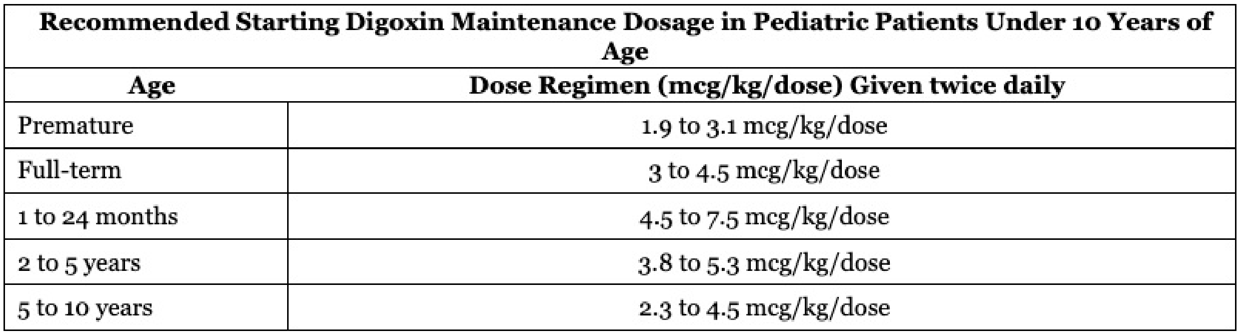
Adults and pediatric patients over 10 years	8 to 12 mcg/kg

Maintenance dosing in adults and pediatric patients over 10 years of age:

2.4 to 3.6 mcg/kg/day given once daily. Doses may be adjusted every 2 weeks according to clinical response, serum drug levels, and toxicity.

PEDIATRIC DOSE

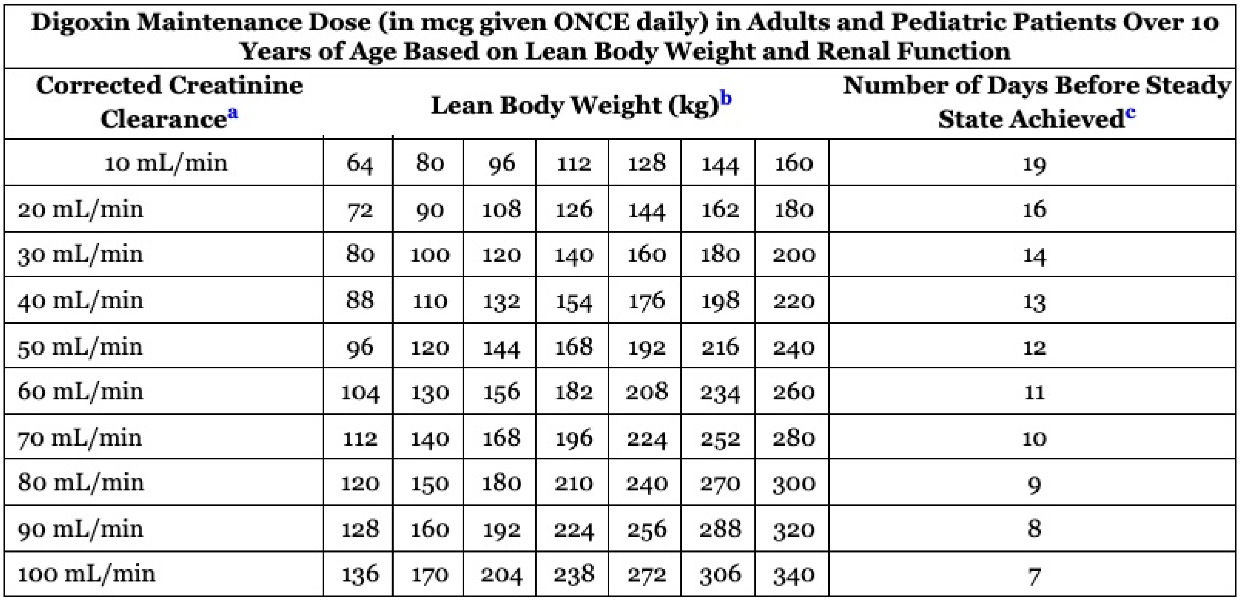
Use 0.1 mg/mL pediatric injection (100 mcg/mL). If using a tuberculin syringe to measure a pediatric dose, do not flush syringe with parenteral solution after contents are injected; may result in an overdose. The recommended starting maintenance dose in pediatric patients under 10 years of age is listed in the following chart. These recommendations assume the presence of normal renal function.



Recommended Starting Digoxin Maintenance Dosage in Pediatric Patients Under 10 Years of Age	
Age	**Dose Regimen (mcg/kg/dose) Given twice daily**
Premature	1.9 to 3.1 mcg/kg/dose
Full-term	3 to 4.5 mcg/kg/dose
1 to 24 months	4.5 to 7.5 mcg/kg/dose
2 to 5 years	3.8 to 5.3 mcg/kg/dose
5 to 10 years	2.3 to 4.5 mcg/kg/dose

DOSE ADJUSTMENTS

The following two charts provide recommended maintenance doses for specific patient populations based on lean body weight and renal function.



Digoxin Maintenance Dose (in mcg given ONCE daily) in Adults and Pediatric Patients Over 10 Years of Age Based on Lean Body Weight and Renal Function								
Corrected Creatinine Clearance[a]	**Lean Body Weight (kg)**[b]							**Number of Days Before Steady State Achieved**[c]
10 mL/min	64	80	96	112	128	144	160	19
20 mL/min	72	90	108	126	144	162	180	16
30 mL/min	80	100	120	140	160	180	200	14
40 mL/min	88	110	132	154	176	198	220	13
50 mL/min	96	120	144	168	192	216	240	12
60 mL/min	104	130	156	182	208	234	260	11
70 mL/min	112	140	168	196	224	252	280	10
80 mL/min	120	150	180	210	240	270	300	9
90 mL/min	128	160	192	224	256	288	320	8
100 mL/min	136	170	204	238	272	306	340	7

[a] For adults, CrCl was corrected to a 70-kg body weight or 1.73 M^2 body surface area. For pediatric patients, the modified Schwartz equation may be used. The formula is based on height in cm and SCr in mg/dL where k is a constant and CCr is corrected to 1.73 M^2 body surface area. During the first year of life, the value of k is 0.33 for preterm infants and 0.45 for term infants. The k is 0.55 for pediatric patients and adolescent girls and 0.7 for adolescent boys:

$$\text{GRF mL/min}/1.73\ M^2 = (k \times \text{Height})/\text{SCr}$$

[b] The doses listed assume average body composition.

[c] If no loading dose administered.

■

Alternatively, the maintenance dose for adults and pediatric patients over 10 years of age may be estimated using the following formula:

Total maintenance dose (mcg) = Loading dose (mcg) × % Daily loss ÷ 100

Where % daily loss = 14 + CrCl ÷ 5.

Digoxin Maintenance Dose[a] (in mcg given TWICE daily) in Pediatric Patients Under 10 Years of Age Based on Lean Body Weight and Renal Function

Corrected Creatinine Clearance[b]	Lean Body Weight (kg)[c]							Number of Days Before Steady State Achieved[d]
10 mL/min	8	16	32	48	64	80	96	19
20 mL/min	9	18	36	54	72	90	108	16
30 mL/min	10	20	40	60	80	100	120	14
40 mL/min	11	22	44	66	88	110	132	13
50 mL/min	12	24	48	72	96	120	144	12
60 mL/min	13	26	52	78	104	130	156	11
70 mL/min	14	28	56	84	112	140	168	10
80 mL/min	15	30	60	90	120	150	180	9
90 mL/min	16	32	64	96	128	160	192	8
100 mL/min	17	34	68	102	136	170	204	7

[a] Recommended doses are to be given twice daily.

[b] The modified Schwartz equation may be used to estimate creatinine clearance. See preceding chart.

[c] The doses listed assume average body composition.

[d] If no loading dose is administered.

■ Reduce dose in patients whose lean weight is an abnormally small fraction of their total body mass because of obesity or edema. ■ Monitor for S/S of digoxin toxicity and clinical response. Adjust dose based on toxicity, efficacy, and blood levels. ■ Reduce dose in partially digitalized patients, in patients with impaired renal function, and in the elderly. ■ Dose reduction may be required before cardioversion. ■ See Drug/Lab Interactions; adjustments may be required with numerous drugs. ■ Renal clearance diminished in neonates, including premature infants; adjust dose as indicated. ■ See Precautions.

DILUTION

Available as a 500 mcg (0.5 mg) in 2 mL injection (250 mcg [0.25 mg] per mL) and as a 100 mcg (0.1 mg) in 1 mL (pediatric) injection. May be given undiluted or each 1 mL may be diluted in 4 mL SWFI, NS, or D5W. Less diluent may cause precipitation. Use diluted solution immediately. Give through Y-tube or three-way stopcock of IV infusion set. See Pediatric Dose.

Storage:

Store unopened vials at CRT protected from light.

COMPATIBILITY

Manufacturer recommends not mixing with other drugs in the same container and not administering simultaneously via the same IV line.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each single dose over a minimum of 5 minutes. Avoid bolus administration. Rapid administration may cause systemic and coronary arteriolar constriction.

ACTIONS

A cardiac glycoside obtained from *Digitalis lanata*. Inhibits Na-K ATPase, the “sodium pump” responsible for moving sodium ions out of cells and potassium ions into cells. The cardiologic consequences of this action are an increase in the force and velocity of myocardial systolic contraction (positive inotropic action), a slowing of the heart rate (negative chronotropic effect), decreased conduction velocity through the AV node, and a decrease in the degree of activation of the sympathetic nervous system and renin-angiotensin system (neurohormonal deactivating effect). Increases cardiac output and left ventricular ejection fraction and lowers pulmonary artery pressure, pulmonary capillary wedge pressure, and systemic vascular resistance. Widely distributed throughout the body. Onset of action is 5 to 30 minutes. Time to peak effect is 1 to 4 hours. Half-life is 1.5 to 2 days. Minimal metabolism. Rapidly excreted in urine, primarily as unchanged drug. Crosses the placenta and is secreted in breast milk.

INDICATIONS AND USES

Treatment of mild to moderate heart failure in adults. ■ To increase myocardial contractility in pediatric patients with heart failure. ■ Control of ventricular response rates in adult patients with chronic atrial fibrillation; see Precautions.

CONTRAINDICATIONS

Ventricular fibrillation and known hypersensitivity to digoxin or other digitalis preparations.

PRECAUTIONS

IV administration is the preferred parenteral route. Used only when oral therapy is not feasible or rapid therapeutic effect is necessary. ■ Commonly prolongs the PR interval; may cause severe sinus bradycardia or sinoatrial block in patients with pre-existing sinus node disease and may cause advanced or complete heart block in patients with pre-existing incomplete AV block. Consider insertion of a pacemaker before treatment with digoxin in these patients. ■ Use in patients with an accessory AV pathway (Wolff-Parkinson-White syndrome) increases risk of ventricular fibrillation and is not recommended. ■ Avoid use in patients with heart failure associated with preserved left ventricular systolic function (e.g., acute cor pulmonale, amyloid heart disease, constrictive pericarditis, idiopathic hypertrophic subaortic stenosis, restrictive cardiomyopathy). Patients with these conditions may experience a decreased cardiac output. Has been used for ventricular rate control in a subgroup of these patients with atrial fibrillation. ■ Avoid use in patients with myocarditis; may precipitate vasoconstriction and promote production of pro-inflammatory cytokines. ■ Use with caution in patients with impaired renal function; risk of toxicity increased; see Dose Adjustments. ■ Use caution in patients with electrolyte disorders because potassium or magnesium depletion sensitizes the myocardium to digoxin; toxicity may occur with serum digoxin concentrations below 2 ng/mL. ■ Use with caution in patients with hypercalcemia. May increase risk of digoxin toxicity. Maintain normocalcemia. ■ Hypocalcemia may nullify effect of digoxin. If calcium levels need to be restored to normal, give calcium slowly and in small amounts. Serious arrhythmias have occurred in digitalized patients receiving calcium. ■ Hypothyroidism may reduce requirements for digoxin. ■ Addressing the underlying condition is suggested in patients with heart failure and/or atrial arrhythmias resulting from hypermetabolic or hyperdynamic states (e.g., hyperthyroidism, hypoxia, or arteriovenous shunt). Atrial arrhythmias associated with hypermetabolic states are particularly resistant to digoxin treatment. ■ Patients with beriberi heart disease may fail to respond adequately to digoxin if the underlying thiamine deficiency is not treated concomitantly. ■ Use is not recommended in patients with myocardial infarction. May cause an increase in myocardial oxygen demand and ischemia. ■ Some clinicians suggest reducing or discontinuing the dose of digoxin for 1 to 2 days before an elective cardioversion of atrial fibrillation to avoid the induction of ventricular arrhythmias, but physicians must consider the consequences of increasing the ventricular response if digoxin is decreased or withdrawn. If digoxin toxicity is suspected, elective cardioversion should be delayed. If it is not prudent to delay cardioversion, the lowest possible energy level should be selected to avoid provoking ventricular arrhythmias. ■ See Drug/Lab Interactions.

Monitor:

Monitor for S/S of digoxin toxicity (anorexia, nausea, vomiting, vision changes, cardiac arrhythmias). ■ Low body weight, advanced age, impaired renal function, hypomagnesemia, hypokalemia, and hypercalcemia may predispose patient to digoxin toxicity. Monitor electrolytes frequently during therapy. Avoid rapid changes. Supplements indicated to maintain normal serum electrolyte levels. ■ Monitor renal function. ■ Monitor digoxin levels. Draw at least 6 hours after the last dose, preferably just before the next dose. Serum digoxin levels less than 0.5 ng/mL have been associated with diminished efficacy, whereas levels above 2 ng/mL have been associated with increased toxicity without increased benefit. ■ Monitor HR and BP. ■ Baseline and periodic ECG monitoring suggested. May prolong the PR interval and cause depression of the ST segment on ECG. ■ The earliest and most frequent manifestation of digoxin toxicity in infants and children is the appearance of cardiac arrhythmias, including sinus bradycardia. ECG monitoring recommended in pediatric patients to avoid intoxication. ■ See Dose Adjustments, Precautions, and Drug/Lab Interactions.

Patient Education:

Review all medications with pharmacist or physician. Capable of numerous drug interactions. ■ Laboratory monitoring of digoxin levels and renal function required. ■ Report any nausea, vomiting, persistent diarrhea, confusion, weakness, or vision disturbances.

Maternal/Child:

Category C: use during pregnancy, labor, and delivery only if clearly needed. ■ Use caution during breast-feeding. Digoxin does distribute into breast milk, but the estimated exposure of the nursing infant to digoxin via breast-feeding is far below the usual infant maintenance dose. ■ Safety and effectiveness of digoxin in the control of ventricular rate in pediatric patients with atrial fibrillation have not been established. ■ Safety and effectiveness in the treatment of heart failure in pediatric patients have not been established in well-controlled studies. However, in published literature of pediatric patients with heart failure of various etiologies, treatment with digoxin has been associated with improvements in hemodynamic parameters and in clinical S/S. ■ Newborn infants display considerable variability in their tolerance to digoxin. Premature and immature infants are particularly sensitive. Dose must be reduced and individualized according to degree of maturity. ■ Carefully titrate dose based on clinical response in pediatric patients with renal disease; see Dose Adjustments. ■ See Monitor.

Elderly:

Monitor carefully. Reduced dose may be indicated. Consider reduced body mass and reduced kidney function.

DRUG/LAB INTERACTIONS

Interactions are numerous. Careful monitoring required when initiating, adjusting, or discontinuing drugs that may interact with digoxin. Monitor serum levels carefully and adjust doses as indicated. ■ Digoxin is a substrate for P-glycoprotein at the level of intestinal absorption, renal tubular secretion, and biliary-intestinal secretion. **Drugs that induce or inhibit P-glycoprotein** have the potential to alter digoxin pharmacokinetics. ■ **Potassium-depleting diuretics** are a major contributing factor to digitalis toxicity. ■ **Calcium** may produce serious arrhythmias in digitalized patients, particularly with too-rapid IV administration. ■ **Amiodarone, propafenone, quinine, spironolactone**, and **verapamil** may increase serum digoxin concentration. Reduce digoxin dose by 15% to 30% and monitor levels. ■ **Quinidine** and **ritonavir** may increase serum levels. Decrease digoxin dose by 30% to 50% and monitor levels. ■ Synergistic with **beta-blockers** and **calcium channel blockers**. Additive effects on AV node conduction may result in bradycardia and/or advanced or complete heart block. ■ **Ivabradine** can increase the risk of bradycardia. ■ **ACE inhibitors, angiotensin receptor blockers, NSAIDs**, and **COX-2 inhibitors** (e.g., celecoxib) may impair excretion of digoxin. ■ Coadministration with **dofetilide** has been associated with a higher incidence of torsades de pointes. ■ Coadministration with **sotalol** has been associated with more proarrhythmic events than when either drug was administered alone. ■ Sudden death was more common in patients receiving digoxin with **dronedarone** than when either drug was given alone.

■ **Teriparatide** transiently increases serum calcium, which may predispose patients to digoxin toxicity. ■ **Succinylcholine** may cause a sudden extrusion of potassium from muscle cells; may cause arrhythmias in digitalized patients. ■ Increased risk of arrhythmias with **sympathomimetic amines** (e.g., dopamine, epinephrine, norepinephrine). ■ Initiation of **thyroid treatment** may require an increase in digoxin dose. ■ Endogenous substances of unknown composition **(digoxin-like immunoreactive substances [DLIS])** can interfere with standard radioimmunoassays for digoxin. This interference usually results in a falsely elevated level but sometimes causes results to be falsely reduced. DLIS are present in up to half of all neonates and in varying percentages of pregnant women, patients with hypertrophic cardiomyopathy, patients with renal or hepatic dysfunction, and other patients who are volume expanded for any reason. **Spironolactone and some traditional Chinese and Ayurvedic medicines** may also interfere with different assays; see manufacturer's prescribing information for further information. ■ See Precautions and Monitor.

SIDE EFFECTS

The overall incidence of adverse reactions with digoxin has been reported as 5% to 20%, with 15% to 20% of adverse reactions considered serious. Cardiac toxicity accounts for about one-half, GI disturbances for about one-fourth, and CNS and other toxicity for about one-fourth of these adverse reactions. ***Cardiac:*** Arrhythmias (e.g., first-degree, second-degree, or third-degree heart block [including asystole]; atrial tachycardia with block; AV dissociation; accelerated junctional [nodal] rhythm; unifocal or multiform ventricular premature contractions [especially bigeminy or trigeminy]; ventricular tachycardia; and ventricular fibrillation). ***GI:*** Abdominal pain, hemorrhagic necrosis of the intestines, intestinal ischemia, nausea and vomiting. ***CNS:*** Apathy, confusion, dizziness, headache, mental disturbances (e.g., anxiety, delirium, depression, hallucinations), and weakness. ***Other:*** Anorexia, gynecomastia, rash, thrombocytopenia, and visual changes.

Toxicity can cause death. The ***most common manifestation of excessive dosing in pediatric patients*** is the appearance of cardiac arrhythmias. Conduction disturbances or supraventricular tachyarrhythmias are the most common type of arrhythmia. Ventricular arrhythmias are less common.

Overdose:

Anorexia, arrhythmias, CNS disturbances, fatigue, hyperkalemia, nausea and vomiting.

ANTIDOTE

Discontinue the drug at the first sign of toxicity, notify the physician, and place the patient on a cardiac monitor. Dosage may be decreased or discontinued. For severe toxicity, digoxin immune Fab is a specific antidote. Consider causes of toxicity (electrolyte disturbances, thyroid, concurrent medications) and correct/treat as indicated. Serum potassium must be obtained before administering potassium salts. See Precautions. Bradycardia and heart block caused by digoxin toxicity may respond to atropine. Ventricular arrhythmias may respond to lidocaine or phenytoin. A temporary pacemaker may also be used. With severe digoxin toxicity, potassium may be released from skeletal muscles, resulting in hyperkalemia. Hyperkalemia, if life-threatening, may be treated with D5W and insulin. Peritoneal dialysis or hemodialysis not effective in overdose.

DIGOXIN IMMUNE FAB (OVINE)

(dih-**JOX**-in im-**MYOUN** fab)
Digibind, DigiFab
Antidote (digoxin intoxication)
pH 6 to 8

USUAL DOSE

Pretreatment:

Testing for sensitivity to sheep serum and/or premedication may be indicated; see Contraindications and Monitor.

Acute toxicity in adults and pediatric patients:

Determine dose by symptoms and clinical findings. Serum concentration may not reflect actual toxicity for 6 to 12 hours. Symptoms of life-threatening toxicity due to digoxin overdose include severe arrhythmias (e.g., VT, VF), progressive bradycardia, second- or third-degree heart block not responsive to atropine, and/or serum potassium levels exceeding 5 to 5.5 mEq/L in adults and 6 mEq/L in pediatric patients.

Dose in numbers of vials based on ingested dose is calculated by dividing the body load of digoxin in milligrams by 0.5. Each vial of ***Digibind*** contains 38 mg/vial and will bind 0.5 mg digoxin. Each vial of ***DigiFab*** contains 40 mg/vial and will bind 0.5 mg of digoxin. Dose may also be based on serum digoxin levels (see package insert; has charts for adults and pediatric patients).

An initial dose of up to 20 vials has been used. 20 vials will bind approximately 50 (0.25 mg) tablets of Lanoxin and should provide adequate treatment of most life-threatening ingestions in adult and pediatric patients. If ingested substance is unknown, if serum digoxin level is not available, or if there is concern about sensitivity to the serum, consider giving 10 vials. Observe clinical response and repeat if indicated. In clinical trials of Digibind the average dose was 10 vials. A single dose may be repeated in several hours if toxicity has not reversed or appears to recur. Febrile reactions are dose related.

Toxicity in chronic therapy:

Adults:

6 vials should be adequate to reverse most cases of toxicity in adults in acute distress or if a serum digoxin concentration is not available.

Pediatric patients:

less than 20 kg: 1 vial should be adequate if signs of toxicity are present.

DILUTION

Each vial must be diluted with 4 mL of SWFI (results in 9.5 mg/mL for Digibind and 10 mg/mL for DigiFab). Mix gently. May be given in this initial dilution or may be further diluted with any desired amount of NS (with ***Digibind,*** 34 mL NS/vial yields 1 mg/mL; with ***DigiFab,*** 36 mL NS/vial yields 1 mg/mL). Consider volume overload in pediatric patients when further diluting in NS. Administer to infants after initial dilution using a tuberculin syringe to deliver an accurate dose with less volume; for extremely small doses, dilute to 1 mg/mL before administration.

Filters:

Digibind:

Must be given through a 0.22-micron membrane filter.

Storage:

Refrigerate unreconstituted vials. Use reconstituted solution promptly or store in refrigerator for up to 4 hours.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Decrease the rate of infusion or discontinue temporarily if an infusion reaction occurs. Do not give as an IV bolus injection unless cardiac arrest is imminent. Be prepared to treat anaphylaxis.

Digibind:

Must be given through a 0.22-micron membrane filter. A single dose as an IV infusion equally distributed over 15 to 30 minutes.

DigiFab:

A single dose as an infusion over 30 minutes.

ACTIONS

Antigen-binding fragments (Fab) prepared from specific antidigoxin antibodies produced in sheep are isolated and purified. Fab fragments bind molecules of digoxin and make them unavailable for binding at their site of action. Freely distributed in extracellular space. Reduces the level of free digoxin in the serum. Onset of action is prompt, with improvement in symptoms of toxicity within 30 minutes. Fab-digoxin complexes are cleared by the kidney. DigiFab is also cleared in the reticuloendothelial system.

INDICATIONS AND USES

Digibind:

Treatment of patients with life-threatening digoxin intoxication or overdose (digoxin).

DigiFab:

Treatment of patients with life-threatening or potentially life-threatening digoxin toxicity or overdose. Not indicated for milder cases of digoxin toxicity.

All formulations:

Indicated for known suicidal or accidental consumption of fatal doses of digoxin, including ingestion of 10 mg or more of digoxin in previously healthy adults, 4 mg (or more than 0.1 mg/kg) in previously healthy pediatric patients, or ingestion causing steady-state serum concentrations greater than 10 ng/mL. ■ Indicated for chronic ingestions causing steady-state serum digoxin concentrations exceeding 6 ng/mL in adults or 4 ng/mL in pediatric patients. ■ Indicated for manifestations of life-threatening toxicity due to digoxin overdose, including severe ventricular arrhythmias (such as VT or VF), progressive bradycardia, or third-degree heart block not responsive to atropine. ■ Also indicated when potassium concentrations are above 5 to 5.5 mEq/L in adults or 6 mEq/L in pediatric patients with rapidly progressive S/S of digoxin toxicity. ■ See Precautions and Maternal/Child.

CONTRAINDICATIONS

None known when used for specific indications. If hypersensitivity exists and treatment is necessary, premedicate with corticosteroids and diphenhydramine and prepare to treat anaphylaxis.

PRECAUTIONS

Administered under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. Cardiac arrest can result from ingestion of more than 10 mg digoxin by healthy adults, 4 mg digoxin by healthy pediatric patients, or serum digoxin levels above 10 ng/mL. ■ Larger doses of digoxin immune Fab act more quickly but increase the possibility of febrile or hypersensitivity reactions. ■ Use caution in impaired cardiac function. Inability to use cardiac glycosides may endanger patient. Support with dopamine or vasodilators. ■ The clinical problem may not be caused by digoxin toxicity if the patient fails to respond to digoxin immune Fab. ■ Consider that multiple drugs may have been used and are producing toxicity in suicide attempts. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Although allergy testing is not required before treating life-threatening digoxin toxicity, patients allergic to ovine proteins or those who have previously received antibodies or Fab fragments produced from sheep are at risk. Determine patient response to any previous injections of serum of any type and history of any allergic-type reactions. In addition, ***DigiFab*** considers that patients with allergies to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may be at risk. ***Digibind*** provides the information below on sensitivity testing; that information is not included in the package insert for ***DigiFab.*** ■ Test for sensitivity if indicated. Make a 1:100 solution by diluting 0.1 mL of reconstituted solution (10 mg/mL) with 9.9 mL sterile NS (100 mcg/mL).

Scratch test: Make a ¼-inch skin scratch through a drop of 1:100 dilution in NS. Inspect the site in 20 minutes. An urticarial wheal surrounded by a zone of erythema is a positive reaction.

Skin test: Inject 0.1 mL (10 mcg) of 1:100 dilution intradermally. Inspect the site in 20 minutes. A urticarial wheal surrounded by a zone of erythema is a positive reaction. Concomitant use of antihistamines may interfere with sensitivity tests. If skin testing causes a systemic reaction, place a tourniquet above the testing site and treat anaphylaxis.

■ Serum digoxin or digitoxin concentration should be obtained before administration if at all possible. These measurements may be difficult to interpret if drawn soon after the last digitalis dose because at least 6 to 8 hours are required for equilibration of digoxin between serum and tissue. ■ Standard treatment of digoxin intoxication includes withdrawal of the intoxicating agent; correction of electrolyte disturbances (especially hyperkalemia), acid-base imbalances, and hypoxia; and treatment of cardiac arrhythmias. ■ Monitor VS, ECG, and potassium concentration frequently during and after drug administration. ■ Monitor for S/S of an acute hypersensitivity reaction (e.g., angioedema, bronchospasm with wheezing or cough, erythema, hypotension, laryngeal edema, pruritus, stridor, tachycardia, urticaria). ■ Potassium may be shifted from inside to outside the cell, causing increased renal excretion. May appear to have hyperkalemia while there is a total body deficit of potassium. When the digoxin effect is reversed, hypokalemia may develop rapidly. ■ Do not redigitalize until all Fab fragments have been eliminated from the body. May take several days. May take longer in severe renal impairment, and reintoxication may occur by release of newly unbound digoxin into the blood. ■ See Precautions and Drug/Lab Interactions.

Maternal/Child:

Category C: use only when clearly indicated and benefits outweigh risks in pregnancy, breast-feeding, and infants. ■ ***Digibind*** indicates that it should be used in infants and children if more than 0.3 mg of digoxin is ingested, if serum digoxin levels are equal to or greater than 6.4 nmol/L, or if there is underlying heart disease.

Patient Education:

Contact the physician immediately if S/S of a delayed hypersensitivity reaction or serum sickness occur (e.g., rash, pruritus, urticaria).

Elderly:

Consider age-related impaired renal function; monitor closely for recurrent toxicity; see Monitor.

DRUG/LAB INTERACTIONS

Will cause a precipitous rise in **total serum digoxin,** but most will be bound to the Fab fragment. Will interfere with digoxin immunoassay measurements until Fab fragment is completely eliminated. ■ **Catecholamines** (e.g., epinephrine) may aggravate digoxin arrhythmias. ■ See skin test in Monitor.

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse is possible. Exacerbation of congestive heart failure and low cardiac output states and increased ventricular response in atrial fibrillation may occur due to withdrawal of digoxin effects. Hypokalemia may be life threatening.

ANTIDOTE

Notify the physician of all side effects. Discontinue the drug and treat anaphylaxis immediately. Corticosteroids, epinephrine, diphenhydramine, oxygen, IV fluids, vasopressors (dopamine), and ventilation equipment must always be available. Resuscitate as necessary. Treat hypokalemia cautiously when necessary. Support exacerbated cardiac conditions as necessary.

DIHYDROERGOTAMINE MESYLATE BBW

(dye-hy-droh-er-**GOT**-ah-meen **MES**-ih-layt)
D.H.E. 45
Ergot alkaloid
Migraine agent
pH 3.2 to 4

USUAL DOSE

Pretreatment:

Verify pregnancy status; see Contraindications.

Abort or prevent headaches:

1 mg (1 mL). May be repeated in 1 hour. No more than 2 doses (2 mg total) may be given IV in 24 hours. Do not exceed 6 mg in 1 week; see Precautions. Administration of an antiemetic (e.g., metoclopramide [Reglan] 10 mg) PO 1 hour before dihydroergotamine is recommended.

Chronic intractable headache:

0.5 mg (0.5 mL). Administer an antiemetic IV (e.g., metoclopramide) about 10 minutes before injection.

Prevention of orthostatic hypotension associated with spinal or epidural anesthesia (unlabeled):

0.5 mg (0.5 mL). Give a few minutes before anesthetic.

PEDIATRIC DOSE

See Maternal/Child. Administration of an antiemetic (e.g., metoclopramide, prochlorperazine), usually PO, 1 hour before dihydroergotamine is recommended.

Pediatric patients 6 to 9 years of age:

100 to 150 mcg (0.1 to 0.15 mg).

Pediatric patients 9 to 12 years of age:

200 mcg (0.2 mg).

Pediatric patients 12 to 16 years of age:

250 to 500 mcg (0.25 to 0.5 mg).

For all age ranges, repeat up to 2 doses at 20-minute intervals if necessary. Another source suggests 250 mcg (0.25 mg) at the start of the attack. Repeat in 1 hour if necessary.

DILUTION

May be given undiluted.

Storage:

Protect ampules from light and heat.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer slowly over 2-3 minutes, or can be given as a continuous infusion.

ACTIONS

An alpha-adrenergic blocking agent that causes constriction of both peripheral and cerebral blood vessels and produces depression of central vasomotor centers. Metabolized by the liver. Metabolites eliminated primarily in feces. Secreted in breast milk.

INDICATIONS AND USES

To abort or prevent vascular headaches (migraine, histamine cephalalgia). Used when rapid control is desired or other routes not feasible. ■ Treatment of chronic intractable headache.

Unlabeled uses:

To prevent orthostatic hypotension associated with spinal or epidural anesthesia. Use SC to enhance heparin effects in preventing postoperative deep vein thrombosis after abdominal, thoracic, or pelvic surgeries or total hip replacement and IM or SC to treat orthostatic hypotension.

CONTRAINDICATIONS

Breast-feeding, coronary artery disease, hepatic or renal disease, hypersensitivity, uncontrolled hypertension, peripheral vascular disease, pregnancy or women who may become pregnant, sepsis. ■ Coadministration with potent CYP3A4 inhibitors, including protease inhibitors and macrolide antibiotics, is contraindicated; see Drug/Lab Interactions.

PRECAUTIONS

IM or SC use is preferred but may be given IV to obtain a more rapid effect. ■ Coadministration with potent CYP3A4 inhibitors, including protease inhibitors and macrolide antibiotics, increases the risk of vasospasm, leading to cerebral ischemia and/or ischemia of the extremities (peripheral). May be serious and/or life threatening; see Contraindications and Drug/Lab Interactions. ■ Use only when a clear diagnosis of migraine has been established. Do not exceed dosing guidelines or use for chronic daily administration; see Usual Dose.

Monitor:

Monitor vital signs; observe closely. ■ See Drug/Lab Interactions.

Patient Education:

Consider birth control options. ■ Take only as directed. ■ Report ineffectiveness or an increase in frequency or severity of headaches. ■ Report chest pain, increased HR, itching, muscle pain or weakness of arms or legs, numbness or tingling of extremities, or swelling.

Maternal/Child:

Category X: avoid pregnancy. See Contraindications. ■ Safety for use in pediatric patients not established. Severe side effects (e.g., extrapyramidal reactions may occur). Pretreatment with an antiemetic may be helpful. Limit pediatric use to patients who have not responded to less toxic treatment.

Elderly:

Increased risk of hypothermia and ischemic complications (e.g., cardiac, peripheral). ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Contraindicated with potent CYP3A4 inhibitors, including **antifungals**, **protease inhibitors** (e.g., ritonavir, nelfinavir, and indinavir), **and macrolide antibiotics**; see Contraindications and Precautions. ■ Administer less potent CYP3A4 inhibitors with caution as vasospasm may occur. **Less potent inhibitors** include, but are not limited to, saquinavir, nefazodone, fluconazole, grapefruit juice, fluoxetine, fluvoxamine, zileuton, and clotrimazole. ■ Opposes vasodilating effects of **nitrates**, decreasing their effectiveness. ■ May cause hypertensive crisis in combination with other **vasopressors** (e.g., epinephrine). ■ May cause peripheral vasoconstriction with ischemia and/or cyanosis with **beta-adrenergic blockers** and **nicotine.**

SIDE EFFECTS

Rare in therapeutic doses, but may include angina pectoris, blindness, gangrene, muscle pains, muscle weakness, nausea, numbness and tingling of the fingers and toes, pleural and retroperitoneal fibrosis, thirst, uterine bleeding, and vomiting.

ANTIDOTE

Discontinue the drug and notify the physician of any side effects. Another drug will probably be chosen if further treatment is indicated. Vasodilators (nitroprusside sodium) and CNS stimulants (e.g., caffeine and sodium benzoate) are indicated as an antidote. Heparin and low-molecular-weight dextran may be used to reduce thrombosis due to excessive vasoconstriction. Hemodialysis may be indicated. Resuscitate as necessary.

DILTIAZEM HYDROCHLORIDE

(dill-**TYE**-a-zem hy-droh-**KLOR**-eyed)
Cardizem
Calcium channel blocker
Antiarrhythmic
pH 3.7 to 4.1

USUAL DOSE

Pretreatment:

Confirmation of diagnosis required; see Monitor.

Bolus:

0.25 mg/kg of body weight initially (20 mg for the average patient). Some patients may respond to an initial dose of 0.15 mg/kg. A second dose of 0.35 mg/kg may be given in 15 minutes if needed to achieve HR reduction (25 mg for the average patient). Any additional bolus doses used to achieve an appropriate response must be individualized to each patient.

Infusion:

Patients with PSVT may respond to bolus doses and may not require an infusion, but to maintain reduction in HR in patients with atrial fibrillation or atrial flutter, immediately follow with an intravenous infusion at an initial rate of 10 mg/hr. Some patients may maintain response with an initial rate of 5 mg/hr. Infusion may be increased by 5 mg/hr increments to a maximum dose of 15 mg/hr. Discontinue infusion within 24 hours. Duration of infusion longer than 24 hours and infusion rates greater than 15 mg/hr have not been studied.

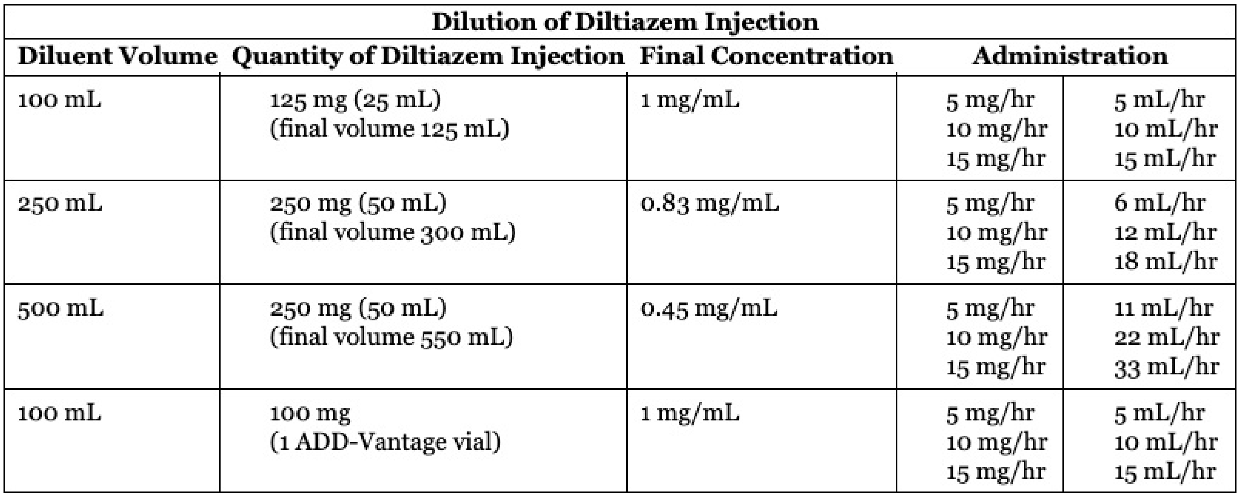
Transition to other antiarrhythmic agents as appropriate. In clinical trials, therapy with agents to maintain reduced heart rate in atrial fibrillation or atrial flutter or for prophylaxis of PSVT was generally started within 3 hours. Medications that were used included digoxin, quinidine, procainamide, calcium channel blockers (e.g., diltiazem, verapamil), beta-blockers (e.g., atenolol, metoprolol, propranolol). See prescribing information for individual agents.

DOSE ADJUSTMENTS

Specific mg/kg dose must be used for patients with low body weights. ■ Reduced dose may be indicated in impaired hepatic or renal function. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on potential for decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

Available as a solution in 25-, 50-, or 125-mg vials (5 mg/mL) and, as a 100-mg ADD-Vantage vial. Dilute according to the following chart.



Dilution of Diltiazem Injection

Diluent Volume	Quantity of Diltiazem Injection	Final Concentration	Administration	
100 mL	125 mg (25 mL) (final volume 125 mL)	1 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	5 mL/hr 10 mL/hr 15 mL/hr
250 mL	250 mg (50 mL) (final volume 300 mL)	0.83 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	6 mL/hr 12 mL/hr 18 mL/hr
500 mL	250 mg (50 mL) (final volume 550 mL)	0.45 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	11 mL/hr 22 mL/hr 33 mL/hr
100 mL	100 mg (1 ADD-Vantage vial)	1 mg/mL	5 mg/hr 10 mg/hr 15 mg/hr	5 mL/hr 10 mL/hr 15 mL/hr

IV injection:

May be given undiluted through Y-site of tubing containing NS, D5W, or D5/½NS.

Infusion:

May be further diluted for infusion in any of the above solutions; see Dilution Chart above.

Filters:

No data available from manufacturer.

Storage:

Store vials containing solution under refrigeration at 2 to 8° C (36 to 46° F). Do not freeze. Some vials may be stored at room temperature for up to 1 month, then discarded. ADD-vantage vials may be stored at CRT. Do not freeze. Following dilution, infusion may be stored at RT or under refrigeration. Use within 24 hours. Discard unused medication and/or solution.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer recommends that **all formulations** not be mixed with any other drugs in the same container and, if possible, that they not be co-infused in the same IV line.

Manufacturer lists **Diltiazem for Injection (ADD-Vantage)** in NS as **compatible** at the **Y-site** with aminophylline, ampicillin, ampicillin/sulbactam, hydrocortisone sodium succinate, insulin (regular U-100), methylprednisolone, nafcillin, and sodium bicarbonate.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each single dose equally distributed over 2 minutes.

Infusion:

5 mg to 15 mg/hr based on patient response. See charts under Dilution for diluent, dose, and infusion rate information. Administer using an infusion pump.

ACTIONS

Directly inhibits the influx of calcium ions through slow channels during membrane depolarization of cardiac and vascular smooth muscle. Effective in supraventricular tachycardias because it slows conduction through the AV node and prolongs the effective refractory period. Has little or no effect on normal AV nodal conduction at normal heart rates. Slows ventricular rate in patients with a rapid ventricular response during atrial fibrillation or atrial flutter. Converts paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm by interrupting the re-entry circuit in AV nodal re-entrant tachycardias and reciprocating tachycardias (e.g. Wolff-Parkinson-White syndrome [WPW]). Because of its effect on vascular smooth muscle, diltiazem decreases total peripheral resistance, resulting in a decrease in both diastolic and systolic BP. In patients with cardiovascular disease, diltiazem reduces BP, systemic vascular resistance, and coronary vascular resistance and increases coronary blood flow. In studies of patients with compromised myocardium (severe CHF, AMI, hypertrophic cardiomyopathy), administration of diltiazem did not produce a significant effect on contractility, left ventricular end diastolic pressure, or pulmonary capillary wedge pressure. The mean ejection fraction and cardiac output/index remained unchanged or increased. Produces less myocardial depression than verapamil. Effective within 3 minutes; maximum effect should occur within 2 to 5 minutes and last for 1 to 3 hours. 70% to 80% bound to plasma proteins. Metabolized in the liver. Half-life is approximately 3.4 hours following a bolus injection and increases to 4.1 to 4.9 hours with continuous infusion. Excreted in urine and feces. Secreted in breast milk.

INDICATIONS AND USES

Temporary control of rapid ventricular rate in atrial fibrillation or atrial flutter unless associated with an accessory bypass tract (e.g., Wolff-Parkinson-White syndrome or short PR syndrome). ■ Rapid conversion of paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm including AV nodal re-entrant tachycardias and reciprocating tachycardias associated with an extranodal accessory pathway (e.g., Wolff-Parkinson-White syndrome or short PR syndrome).

CONTRAINDICATIONS

Atrial fibrillation or flutter when associated with an accessory bypass tract (e.g., Wolff-Parkinson-White or short PR syndrome), cardiogenic shock, known hypersensitivity to diltiazem, second- or third-degree AV block or sick sinus syndrome (unless functioning ventricular pacemaker in place), severe hypotension, patients receiving IV beta-adrenergic blocking agents (e.g., atenolol [Tenormin], propranolol [Inderal]) within a few hours, ventricular tachycardia. Not recommended for wide QRS tachycardias of uncertain origin.

PRECAUTIONS

For short-term use only. ■ Administration of IV diltiazem should take place in a facility with adequate personnel and emergency drugs and equipment (including a defibrillator) to monitor the patient and respond to any medical emergency. ■ While diltiazem will effectively decrease HR, cardioversion will probably be required to convert atrial fibrillation or atrial flutter to a normal sinus rhythm. ■ Appropriate vagal maneuvers (e.g., Valsalva maneuver) recommended before use of diltiazem in patients with paroxysmal supraventricular tachycardia if clinically appropriate. ■ Use IV diltiazem with caution in patients with pre-existing impaired ventricular function (e.g., congestive heart failure, acute myocardial infarction, or pulmonary congestion documented by x-ray); may exacerbate disease. Use of oral diltiazem in these patients is contraindicated. ■ May cause second- or third-degree AV block in sinus rhythm; discontinue diltiazem if high degree AV block occurs. ■ Can cause life-threatening tachycardia with severe hypotension in atrial fibrillation or flutter in patients with an accessory bypass tract and periods of asystole in patients with sick sinus syndrome; see Contraindications. ■ Use with caution in patients with PSVT who are hemodynamically compromised or are taking other drugs that decrease any or all of the following: peripheral resistance, intravascular volume, myocardial contractility or conduction. Symptomatic hypotension is possible. ■ Use with caution in impaired renal or hepatic function. ■ Ventricular premature beats (VPBs) may occur on conversion of PSVT to sinus rhythm; considered to have no clinical significance. ■ Rare instances of significant liver enzymes and other phenomena consistent with acute hepatic injury have been reported with use of oral diltiazem. ■ Rare cases of dermatologic toxicity progressing to erythema multiforme and/or exfoliative dermatitis has been reported with oral diltiazem.

Monitor:

Accurate pretreatment diagnosis differentiating wide-complex QRS tachycardia of supraventricular origin from ventricular origin is imperative. ■ Continuous ECG monitoring required. ■ Monitor BP and HR closely. ■ See Drug/Lab Interactions.

Maternal/Child:

Use during pregnancy only if potential benefit justifies the potential risk to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Overall difference in response between the elderly and younger patients has not been identified, but greater sensitivity of some older individuals cannot be ruled out; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Diltiazem is both a substrate and inhibitor of CYP3A4. Other **drugs that are substrates, inhibitors, or inducers of CYP3A4** may have a significant impact on the efficacy or toxicity of diltiazem. Patients taking drugs that are substrates of CYP3A4 may require dose adjustment when starting or stopping concomitantly administered diltiazem. ■ Do not give concomitantly (within a few hours) with **IV beta-adrenergic blocking agents**; see Contraindications. May result in bradycardia, AV block, and/or depression of contractility. Use extreme caution if these drugs are administered orally or if patient has received before admission; usually tolerated. ■ May result in additive effects with **any agent known to affect cardiac contractility and/or SA or AV node conduction** (e.g., digoxin, beta-blockers). ■ Is used with **digoxin,** but monitor for excessive slowing of HR and/or AV block. ■ Coadministration with **amiodarone** or **clonidine** may result in bradycardia. Monitor closely. ■ May increase effects of certain **benzodiazepines** (e.g., midazolam), **buspirone**, and **methylprednisolone**. ■ May increase serum concentrations of **carbamazepine**, **cyclosporine**, **digoxin**, some **HMG-CoA reductase inhibitors** (e.g., atorvastatin, lovastatin, simvastatin), **nifedipine, quinidine, sirolimus, and tacrolimus**. Monitor serum levels and/or monitor for S/S of toxicity. ■ May potentiate cardiac effects of **anesthetics** (e.g., depression of cardiac contractility, conductivity, automaticity, and vascular dilation); titrate both drugs carefully. ■ Metabolism may be decreased and serum concentrations increased by **cimetidine** and some **azole antifungal agents** (e.g., itraconazole). ■ Metabolism may be increased and serum concentrations decreased by **CYP3A4 inducers** (e.g., rifampin). Avoid use if possible and consider alternative therapy. ■ May increase exposure to **ivabradine** and exacerbate bradycardia and conduction disturbances. Avoid concomitant use. ■ May enhance neurotoxicity of lithium. Variable effects on lithium concentrations have been reported.

SIDE EFFECTS

Arrhythmia (junctional rhythm or isorhythmic dissociation), flushing, hypotension (asymptomatic and symptomatic), and injection site reactions (burning, itching) occurred most frequently and were most often mild and transient but could have serious potential. Amblyopia, asthenia, asystole, atrial flutter, AV block (first- or second-degree), bradycardia, chest pain, congestive heart failure, constipation, dizziness, dry mouth, dyspnea, edema, elevated alkaline phosphatase and AST, headache, hyperuricemia, nausea, paresthesia, pruritus, sinus node dysfunction, sinus pause, sweating, syncope, ventricular arrhythmias, ventricular fibrillation, ventricular tachycardia, and vomiting have occurred. Additional side effects have been reported with oral diltiazem.

ANTIDOTE

Notify physician promptly of all side effects. Treatment will depend on clinical situation. IV fluids or the Trendelenburg position may be required for BP support. Vasopressors (e.g., dopamine or norepinephrine) may be used, if needed. Administer atropine (0.6 to 1 mg) for bradycardia. If no response, administer isoproterenol cautiously. Discontinue diltiazem if a high-degree AV block occurs. Treat with atropine as above. Fixed-high-degree AV block should be treated with cardiac pacing. Treat cardiac failure with inotropic agents (isoproterenol, dopamine, or dobutamine) and diuretics. Calcium chloride or calcium gluconate have been used to reverse the pharmacologic effects of diltiazem overdose with variable results. Treat hypersensitivity reactions or resuscitate as necessary. Not removed by hemodialysis.

DIMENHYDRINATE

(dye-men-**HY**-drih-nayt)
Antihistamine
Antiemetic
Antivertigo agent
pH 6.4 to 7.2

USUAL DOSE

50 mg every 4 hours as needed. Up to 100 mg every 4 hours has been used. Do not exceed 400 mg/24 hr.

PEDIATRIC DOSE

See Contraindications and Maternal/Child.

Pediatric patients 2 to 12 years of age:

1.25 mg/kg of body weight/dose every 6 hours as needed. Do not exceed 300 mg/24 hr. Some sources state that the IV dosage has not been determined for pediatric patients and recommend IM administration.

DOSE ADJUSTMENTS

Caution and lower-end dosing suggested in elderly patients. Consider age-related impaired organ function and concomitant disease or drug therapy. ■ Consider dose reduction in patients with hepatic impairment.

DILUTION

The 50 mg/mL concentration is intended for IM use only. For IV use, each 1 mL (50 mg) must be diluted in 10 mL NS.

Storage:

Store at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 50 mg or fraction thereof properly diluted as an injection over a minimum of 2 minutes.

ACTIONS

An antihistamine with antiemetic and antivertigo actions. Has CNS depressant effects. As an antihistamine, it competes with histamine for H1 receptor sites on effector cells. Its mode of action as an antiemetic is unknown but may be related to central anticholinergic actions or an effect on chemoreceptive triggers. It diminishes vestibular stimulation and depresses labyrinthine function, raising the threshold of susceptibility, especially to motion sickness. Metabolized in the liver (cytochrome P_{450} system) and excreted in changed form in the urine. Secreted in breast milk.

INDICATIONS AND USES

Prevention and/or treatment of nausea and vomiting, dizziness, or vertigo of motion sickness.

CONTRAINDICATIONS

Hypersensitivity to dimenhydrinate or its components. ■ Pediatric patients under 2 years of age; see Precautions and Maternal/Child. Also may contain benzyl alcohol.

PRECAUTIONS

Cross-sensitivity with other antihistamines may occur; use caution in patients with allergies. ■ Will induce drowsiness, often a desirable reaction. ■ Use caution in patients with impaired liver function, bladder neck obstruction, narrow-angle glaucoma, prostatic hypertrophy, and urinary retention. ■ May produce a paradoxical hyperexcitation in pediatric patients and the elderly; overdose has caused convulsions, hallucinations, and death in infants and small children. ■ An antiemetic; may mask signs of overdose of other medications or symptoms of appendicitis.

Monitor:

Monitor V/S; observe closely. ■ Maintenance of a recumbent position is preferred; assist with ambulation. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

May cause drowsiness and dizziness; request help for ambulation. ■ Do not drive or operate hazardous equipment until effects have worn off. ■ Avoid alcohol and other CNS depressants (e.g., diazepam [Valium], narcotics).

Maternal/Child:

Category B: use during pregnancy only if clearly needed. ■ Anticholinergic effect may inhibit lactation. A breast-feeding infant may risk side effects (e.g., unusual excitement, irritability); discontinue breast-feeding. ■ Safety for use in pediatric patients under 2 years of age not established; see Precautions. ■ Newborn and premature infants are more susceptible to CNS excitation and convulsions; see Contraindications.

Elderly:

See Dose Adjustments. ■ May cause confusion, dizziness, hypotension, paradoxical hyperexcitability, and/or sedation. ■ May have increased sensitivity to cholinergic effects (e.g., dry mouth, urinary retention). Discontinue dimenhydrinate if these effects are severe.

DRUG/LAB INTERACTIONS

May mask early symptoms of ototoxicity if given in conjunction with **other potentially ototoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], furosemide, large doses of aspirin). ■ **Alcohol and CNS depressants** will produce an additive effect. ■ Anticholinergic effects are increased with **other anticholinergic drugs** (e.g., phenothiazines [e.g., prochlorperazine (Compazine)], tricyclic antidepressants [e.g., amitriptyline (Elavil)]); paralytic ileus or other anticholinergic side effects may occur. ■ **MAO inhibitors** (e.g., selegiline [Eldepryl]) prolong the anticholinergic and CNS depressant effects of dimenhydrinate; concurrent use is not recommended. ■ May affect the **results of skin testing for allergies.**

SIDE EFFECTS

Blurred vision; difficult or painful urination; dizziness; drowsiness; dryness of the mouth, nose, and throat; nausea and vomiting; paradoxical reaction; photosensitivity; ringing or buzzing in the ears may occur. Many other side effects can occur, including anaphylaxis and cardiac arrhythmias. Overdose produces CNS excitation in pediatric patients, convulsions, hallucinations, hyperpyrexia, marked irritability, and death.

ANTIDOTE

For exaggerated drowsiness or other severe side effects (e.g., anticholinergic effects in the elderly, paradoxical excitement in pediatric patients or the elderly), discontinue the drug and notify the physician. Side effects will usually subside within a few hours or may be treated symptomatically. Treat convulsions with diazepam (Valium) initially; they may then be controlled with phenytoin (Dilantin) or phenobarbital (Luminal). The use of epinephrine to treat hypotension is not recommended; may further decrease blood pressure. Resuscitate as necessary.

DINUTUXIMAB BBW

(dye-new-**TUX**-ih-mab)
Unituxin
Antineoplastic
(monoclonal antibody)
pH 6.8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Verify adequate hematologic, respiratory, hepatic, and renal function ***before initiating each course of dinutuximab***; see Monitor.

Administer required premedication and hydration ***before initiation of each dinutuximab infusion.***

Hydration:

Administer NS 10 mL/kg as an IV infusion over 1 hour just before initiating each dinutuximab infusion.

Premedication:

Analgesics:

Immediately before initiating dinutuximab infusion, administer morphine sulfate 50 mcg/kg IV. Follow with a morphine sulfate drip at an infusion rate of 20 to 50 mcg/kg/hr during and for 2 hours after completion of dinutuximab. Additional 25 to 50 mcg/kg IV doses of morphine may be administered as needed for pain up to once every 2 hours followed by an increase in the morphine infusion rate in clinically stable patients. Consider using fentanyl or hydromorphone (Dilaudid) if morphine is not tolerated. If pain is not managed adequately with opioids, consider use of gabapentin (Neurontin) or lidocaine in conjunction with IV morphine.

Antihistamines:

20 minutes before initiating dinutuximab infusion, administer an antihistamine such as diphenhydramine 0.5 to 1 mg/kg (maximum dose of 50 mg) IV over 10 to 15 minutes. Repeat every 4 to 6 hours as tolerated during the dinutuximab infusion.

Antipyretics:

20 minutes before initiating dinutuximab infusion, administer acetaminophen 10 to 15 mg/kg (maximum dose 650 mg). Repeat every 4 to 6 hours as needed for fever or pain. Administer ibuprofen 5 to 10 mg/kg every 6 hours as needed for control of persistent fever or pain.

Dinutuximab:

17.5 mg/M^2/day as an IV infusion over 10 to 20 hours for 4 consecutive days for a maximum of 5 cycles. See Rate of Administration.

Schedule of Dinutuximab Administration for Cycles 1, 3, and 5						
Cycle Day	**1 through 3**	**4**	**5**	**6**	**7**	**8 through 24**[a]
Dinutuximab		X	X	X	X	

[a]Cycles 1, 3, and 5 are 24 days in duration.

Schedule of Dinutuximab Administration for Cycles 2 and 4						
Cycle Day	**1 through 7**	**8**	**9**	**10**	**11**	**12 through 32**[a]
Dinutuximab		X	X	X	X	

[a]Cycles 2 and 4 are 32 days in duration.

DOSE ADJUSTMENTS

Manage adverse reactions by infusion interruption, infusion rate reduction, dose reduction, or permanent discontinuation of dinutuximab as outlined in the following charts; see Rate of Administration, Monitor, and Antidote.

Dinutuximab Dose Modification for Infusion-Related Reactions		
Mild to moderate adverse reactions (e.g., transient rash, fever, chills, localized urticaria) that respond promptly to symptomatic treatment	Onset of reaction	Reduce dinutuximab infusion rate to 50% of the previous rate and monitor closely.
	After resolution	Gradually increase infusion rate up to a maximum rate of 1.75 mg/M^2/hr.
Prolonged or severe adverse reactions (e.g., mild bronchospasm without other symptoms, angioedema that does not affect the airway)	Onset of reaction	Immediately interrupt dinutuximab.
	After resolution	If S/S resolve rapidly, resume dinutuximab infusion at 50% of the previous rate and monitor closely.
	First recurrence	Discontinue dinutuximab until the following day. If symptoms resolve and continued treatment is warranted, premedicate with hydrocortisone 1 mg/kg IV (maximum dose 50 mg) and administer dinutuximab at a rate of 0.875 mg/M^2/hr in an intensive care unit.
	Second recurrence	Permanently discontinue dinutuximab.

Dinutuximab Dose Modification for Capillary Leak Syndrome		
Moderate to severe but not life-threatening capillary leak syndrome	Onset of reaction	Immediately interrupt dinutuximab.
	After resolution	Resume dinutuximab infusion at 50% of the previous rate.
Life-threatening capillary leak syndrome	Onset of reaction	Discontinue dinutuximab for the current cycle.
	After resolution	In subsequent cycles, administer dinutuximab at 50% of the previous rate.
	First recurrence	Permanently discontinue dinutuximab.

Dinutuximab Dose Modification for Hypotension Requiring Medical Intervention		
Symptomatic hypotension, systolic blood pressure (SBP) less than lower limit of normal for age, or SBP decreased by more than 15% compared to baseline	Onset of reaction	Interrupt dinutuximab infusion.
	After resolution	Resume dinutuximab infusion at 50% of the previous rate. If blood pressure remains stable for at least 2 hours, increase the infusion rate as tolerated up to a maximum rate of 1.75 mg/M^2/hr.

Dinutuximab Dose Modification for Severe Systemic Infection or Sepsis		
Infections such as severe Grade 3 or 4 bacteremia requiring IV antibiotics or other urgent intervention.	Onset of reaction	Discontinue dinutuximab until resolution of infection, and then proceed with subsequent cycles of therapy.

Dinutuximab Dose Modification for Neurologic Disorders of the Eye		
Disorders such as blurred vision, dilated pupil with sluggish light reflex, eyelid ptosis, fixed or unequal pupils, mydriasis, papilledema, optic nerve disorder, or other visual disturbances that do not cause vision loss.	Onset of reaction	Discontinue dinutuximab infusion until resolution.
	After resolution	Reduce dinutuximab dose by 50%.
	First recurrence or if accompanied by visual impairment	Permanently discontinue dinutuximab.

Dinutuximab Dose Modification for Severe Pain	
Severe pain	Decrease dinutuximab infusion rate to 0.875 mg/M²/hr. Discontinue dinutuximab if pain is not adequately controlled despite infusion rate reduction and institution of maximum supportive measures. See Premedication, Analgesics.

DILUTION

Available in a single-use vial containing 17.5 mg/5 mL (3.5 mg/mL). Do not use if solution is cloudy, has pronounced discoloration, or contains particulate matter. Aseptically withdraw the required volume of dinutuximab and inject into a 100-mL bag of NS. Mix by gentle inversion. ***Do not shake.***

Filters:

Specific information not available.

Storage:

Before use, store in refrigerator at 2° to 8° C (36° to 46° F) in outer carton to protect from light. Do not freeze or shake vials. Diluted solution may be refrigerated, but the infusion must begin within 4 hours of preparation. Discard diluted solution 24 hours after preparation. Discard unused contents of vial.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

For use as a diluted IV infusion only. Do not administer as an IV push or bolus. Initiate at an infusion rate of 0.875 mg/M²/hr for 30 minutes. Gradually increase as tolerated to a maximum rate of 1.75 mg/M²/hr. Manage adverse reactions by infusion interruption, infusion rate reduction, dose reduction, or permanent discontinuation of dinutuximab; see Dose Adjustments.

ACTIONS

Dinutuximab is a chimeric monoclonal antibody produced in the murine myeloma cell line SP2/0. It binds to the glycolipid GD2. This glycolipid is expressed on neuroblastoma cells and on normal cells of neuroectodermal origin, including the central nervous system and peripheral nerves. Dinutuximab binds to cell surface GD2 and induces cell lysis of GD2-expressing cells through antibody-dependent, cell-mediated cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC). Terminal half-life is approximately 10 days.

INDICATIONS AND USES

Treatment of pediatric patients with high-risk neuroblastoma who achieve at least a partial response to prior first-line, multiagent, multimodality therapy. Used in combination with granulocyte-macrophage colony-stimulating factor (GM-CSF), interleukin-2 (IL-2), and 13-*cis*-retinoic acid (RA).

CONTRAINDICATIONS

History of anaphylaxis with dinutuximab.

PRECAUTIONS

For use as a diluted IV infusion only. Do not administer as an IV push or bolus. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Serious and potentially life-threatening infusion reactions requiring urgent intervention, including blood pressure support, bronchodilator therapy, corticosteroids, infusion rate reduction, infusion interruption, or permanent discontinuation of dinutuximab, have occurred. ■ Pain was reported in the majority of patients despite pretreatment with analgesics. Pain was most commonly described as abdominal, back, extremity, or musculoskeletal pain; chest pain; generalized pain; neuralgia; and arthralgia. ■ Dinutuximab causes serious neurologic adverse reactions, including severe neuropathic pain and peripheral neuropathy. Severe neuropathic pain occurs in the majority of patients. Administer IV opioids before, during, and for 2 hours after completion of the infusion. Severe motor neuropathy has occurred; resolution did not occur in all cases. ■ Urinary retention that persists for weeks to months after discontinuation of opioids has occurred. ■ Transverse myelitis has occurred. ■ Reversible posterior leukoencephalopathy syndrome (RPLS) has occurred. ■ Capillary leak syndrome was reported. ■ Severe hypotension was reported. Prehydration is required; see Usual Dose. ■ Severe bacteremia requiring IV antibiotics or other urgent intervention has occurred. ■ Neurologic disorders of the eye have been reported. ■ Bone marrow suppression (e.g., severe anemia, febrile neutropenia, neutropenia, and thrombocytopenia) was reported. ■ Electrolyte abnormalities (e.g., hypocalcemia, hypokalemia, and hyponatremia) occur in at least 25% of patients, and some developed inappropriate antidiuretic hormone secretion resulting in severe hyponatremia. ■ Hemolytic-uremic syndrome has been reported. ■ Has not been studied in patients with hepatic or renal impairment. ■ A protein substance; has a potential for immunogenicity. ■ See Dose Adjustments, Monitor, Maternal/Child, and Antidote.

Monitor:

Verify that patients have adequate hematologic, respiratory, hepatic, and renal function before initiating each course of dinutuximab therapy. ■ Administer required IV hydration and premedication with antihistamines, analgesics, and antipyretics before each dose. ■ Obtain baseline CBC and platelets and monitor closely during therapy. ■ Obtain baseline serum electrolytes and monitor daily during therapy. ■ Monitor for S/S of an infusion reaction during and for at least 4 hours after completion of each infusion (e.g., bronchospasm, dyspnea, facial and upper airway edema, hypotension, stridor, urticaria). Infusion reaction generally occurred during or within 24 hours of completing an infusion. Because of an overlap in S/S, it is difficult to distinguish between infusion reactions and hypersensitivity reactions. ■ Assess pain frequently; see Usual Dose, Dose Adjustments, and Antidote. ■ Monitor for S/S of peripheral sensory or motor neuropathy (e.g., burning, numbness, tingling, or weakness). ■

Monitor for S/S of prolonged urinary retention. ■ Promptly evaluate any patient with S/S of transverse myelitis (e.g., incontinence, paresthesia, sensory loss, or weakness). Permanently discontinue if patient develops transverse myelitis. ■ Monitor for S/S of RPLS (e.g., hypertension, lethargy, seizures, severe headache, or vision changes). If S/S of RPLS occur, institute appropriate medical treatment and permanently discontinue. ■ Monitor for S/S of capillary leak syndrome (e.g., edema, fatigue, hemoconcentration, hypotension, light-headedness, nausea, weakness). Interrupt or discontinue dinutuximab. ■ Monitor blood pressure closely. For symptomatic hypotension, interrupt or discontinue dinutuximab and provide supportive management. ■ Monitor for S/S of infection and temporarily discontinue dinutuximab until resolution of the infection. ■ Monitor for S/S of eye disorders (e.g., dilated pupil with sluggish light reflex or other visual disturbances that do not cause vision loss). Interrupt dinutuximab infusion until resolution. ■ Monitor for S/S of hemolytic-uremic syndrome (e.g., anemia, decreased urine output, dizziness, edema, fatigue, hematuria, pallor, renal insufficiency). If symptoms appear, discontinue dinutuximab. ■ See Dose Adjustments, Precautions, Maternal/Child, and Antidote.

Patient Education:

Review manufacturer's medication guide. ■ Effective contraception required during treatment with dinutuximab and for at least 2 months following the last dose of dinutuximab. ■ Promptly report a known or suspected pregnancy. ■ Some side effects may require extensive supportive treatment and interruption or discontinuation of dinutuximab. ■ Promptly report S/S of an infusion reaction (e.g., difficulty breathing, dizziness, facial or lip swelling, light-headedness, urticaria) that occur during or within 24 hours following the infusion. ■ Promptly report severe or worsening pain and S/S of neuropathy such as burning, numbness, tingling, or weakness. ■ Promptly report edema, fatigue, light-headedness, or nausea. ■ Promptly report blurred vision, diplopia, photophobia, ptosis, or unequal pupil size. ■ Promptly report bruising or fatigue. ■ Promptly report heart palpitations, muscle cramping, or seizures. ■ Promptly report decreased urine output, edema, fainting, hematuria, inability to urinate, or pallor. ■ Promptly report S/S of RPLS (e.g., hypertension, lethargy, seizures, severe headache, or vision changes).

Maternal/Child:

Avoid pregnancy. Based on its mechanism of action, dinutuximab can cause fetal harm when administered to a pregnant woman. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients as part of a multiagent, multimodality therapy have been established; see Indications.

Elderly:

Safety and effectiveness for use in the elderly have not been established.

DRUG/LAB INTERACTIONS

No drug-drug interaction studies have been reported with dinutuximab.

SIDE EFFECTS

The most common side effects reported in 25% or more of patients are anemia, capillary leak syndrome, diarrhea, fever, hypoalbuminemia, hypocalcemia, hypokalemia, hyponatremia, hypotension, increased ALT and AST, infusion reactions, lymphopenia, neutropenia, pain, thrombocytopenia, urticaria, and vomiting. The most common serious side effects reported in 5% or more of patients include capillary leak syndrome, fever, hypokalemia, hypotension, infections, infusion reactions, and pain. Decreased appetite, device-related infections, edema, hemorrhage, hyperglycemia, hypertension, hypertriglyceridemia, hypomagnesemia, hypophosphatemia, hypoxia, increased serum creatinine, nausea, neurologic disorders of the eye (e.g., blurred vision, eyelid ptosis, fixed or unequal pupils, mydriasis, optic nerve disorder, papilledema, photophobia), peripheral neuropathy, proteinuria, tachycardia, and weight increase have also been reported.

Post-Marketing:

Neurotoxicity: prolonged urinary retention, transverse myelitis, and reversible posterior leukoencephalopathy syndrome (RPLS).

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Permanently discontinue dinutuximab in patients with any of the following: (1) Grade 3 or 4 anaphylaxis (life-threatening infusion reactions), (2) Grade 3 or 4 serum sickness, (3) Grade 3 pain unresponsive to maximum supportive measures, (4) Grade 4 sensory neuropathy or Grade 3 sensory neuropathy that interferes with daily activities for more than 2 weeks, (5) Grade 2 or greater peripheral motor neuropathy, (6) urinary retention that persists after discontinuation of opioids, (7) transverse myelitis, (8) reversible posterior leukoencephalopathy syndrome (RPLS), (9) subtotal or total vision loss, or (10) Grade 4 hyponatremia despite appropriate fluid management. Interrupt or discontinue dinutuximab and provide supportive management in (1) severe or prolonged infusion reactions, (2) symptomatic or severe capillary leak syndrome, (3) systemic infection, (4) symptomatic hypotension, and (5) patients with a dilated pupil and a sluggish light reflex or other visual disturbances that do not cause vision loss. Permanently discontinue dinutuximab and provide supportive management for signs of hemolytic-uremic syndrome. Treat these side effects aggressively; see Dose Adjustments, Precautions, and Monitor.

DIPHENHYDRAMINE HYDROCHLORIDE

(dye-fen-**HY**-drah-meen hy-droh-**KLOR**-eyed)
Benadryl, Benadryl PF, Diphenhydramine PF
Antihistamine
Antidyskinetic/antiparkinsonism
Antiemetic
Antivertigo agent
Sedative-hypnotic
pH 4 to 6.5

USUAL DOSE

10 to 50 mg. Up to 100 mg may be given. Individualize dose based on patient symptoms and response. Total dosage should not exceed 400 mg/24 hr.

PEDIATRIC DOSE

See Contraindications and Maternal/Child.

Pediatric patients after neonatal period:

1.25 mg/kg/dose every 6 hours as needed or 150 mg/M^2/24 hr in equally divided doses given every 6 hours (37.5 mg/M^2 every 6 hours). Never exceed a total dosage of 300 mg/24 hr.

Anaphylaxis or phenothiazine overdose:

1 to 2 mg/kg IV slowly.

DOSE ADJUSTMENTS

Reduce dose for the elderly or debilitated. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted.

Filters:

No data available from manufacturer.

Storage:

Store below 40° C (104° F), preferably between 15° and 30° C (59° and 86° F). Protect from light and freezing.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

25 mg or fraction thereof over 1 minute. Extend injection time in nonemergency situations and pediatric patients. See Maternal/Child.

ACTIONS

A potent antihistamine, it is capable of blocking the effects of histamine at various receptor sites, either eliminating a hypersensitivity reaction or greatly modifying it. It also has anticholinergic (antispasmodic), antiemetic, antivertigo, and sedative effects. It has rapid onset of action and is widely distributed throughout the body, including the CNS. A portion of this drug is metabolized in the liver; the rest is excreted unchanged in the urine. Half-life is 1 to 4 hours. Some secretion may occur in breast milk.

INDICATIONS AND USES

Allergic reactions to blood or plasma. ■ Supplemental therapy to epinephrine in anaphylaxis and other uncomplicated allergic/hypersensitivity reactions requiring prompt treatment (e.g., angioedema, pruritus, urticaria). ■ Preoperative or generalized sedation. ■ Management of parkinsonism, including drug-induced (e.g., phenothiazines). ■ Severe nausea and vomiting. ■ Motion sickness. ■ To replace oral therapy when it is impractical or contraindicated.

CONTRAINDICATIONS

Breast-feeding, hypersensitivity to antihistamines, newborn or premature infants.

PRECAUTIONS

IV route used only in emergency situations. ■ Avoid SC or perivascular injection. ■ Use with extreme caution in infants, children, elderly or debilitated individuals, asthmatic attack, bladder neck obstruction, narrow-angle glaucoma, lower respiratory tract infections, prostatic hypertrophy, pyloroduodenal obstruction, and stenosing peptic ulcer.

Monitor:

Will induce drowsiness. ■ Monitor vital signs; observe closely. ■ See Drug/Lab Interactions.

Patient Education:

Do not drive or operate hazardous equipment until effects wear off. ■ May cause drowsiness and dizziness; request help to ambulate. ■ Avoid alcohol and other CNS depressants.

Maternal/Child:

See Contraindications, Precautions, Monitor, and Side Effects. ■ Category B: use only when clearly needed. May increase risk of abnormalities during the first trimester. ■ Not recommended during breast-feeding. Small amounts may be distributed into breast milk, causing irritability or excitement in infants. ■ Use extreme caution in infants and children; may cause hallucinations, convulsions, or death. May also reduce mental alertness and cause paradoxical excitation.

Elderly:

See Dose Adjustments, Precautions, Monitor, and Side Effects. ■ May cause confusion, dizziness, hyperexcitability, hypotension, and/or sedation. ■ Sensitivity to anticholinergic effects is increased (e.g., blurred vision, constipation, dry mouth, urinary retention).

DRUG/LAB INTERACTIONS

Increases effectiveness of **epinephrine** and is often used in conjunction with it. ■ Additive central nervous system effects with **alcohol, other CNS depressants** (e.g., hypnotics, sedatives, and tranquilizers), and **procarbazine**. Reduced dose of potentiated drug may be indicated. ■ **MAO inhibitors** (e.g., selegiline) prolong and intensify the anticholinergic (drying) effects of antihistamines. Concurrent use not recommended. ■ Effectiveness of many drugs is reduced in combination with diphenhydramine because of increased metabolism. ■ May inhibit the wheal and flare reaction to **antigen skin tests.**

SIDE EFFECTS

Rare when used as indicated: anaphylaxis; blurring of vision; confusion; constipation; diarrhea; difficulty in urination; diplopia; drowsiness; drug rash; dryness of mouth, nose, and throat; epigastric distress; headache; hemolytic anemia; hypotension; insomnia; nasal stuffiness; nausea; nervousness; palpitations; photosensitivity; rapid pulse; restlessness; thickening of bronchial secretions; tightness of the chest and wheezing; tingling, heaviness, weakness of hands; urticaria; vertigo; vomiting. Overdose may cause convulsions, hallucinations, and death in pediatric patients.

ANTIDOTE

For exaggerated drowsiness or other disturbing side effects, discontinue the drug and notify the physician. Side effects will usually subside within a few hours or may be treated symptomatically. Treat hypotension promptly; may lead to cardiovascular collapse. Use dopamine, norepinephrine, or phenylephrine. Epinephrine is contraindicated for hypotension; further hypotension will occur. Propranolol is the drug of choice for ventricular arrhythmias. Treat convulsions with diazepam 0.1 mg/kg IV slowly. Some central anticholinergic effects may require physostigmine. Avoid analeptics (e.g., caffeine); may cause convulsions. Epinephrine must be available to treat anaphylaxis. Resuscitate as necessary.

DIPHTHERIA ANTITOXIN

(dif-**THER**-e-ah an-tie-**TOX**-sin)
Immunizing agent (active)

USUAL DOSE

Pretreatment:

Testing for sensitivity to horse serum required before use; see Precautions/Monitor.
Suggested ranges for adults and pediatric patients to be given as a single dose.

Pharyngeal or laryngeal disease of 48 hours' duration:

20,000 to 40,000 units.

Nasopharyngeal lesions:

40,000 to 60,000 units.

Extensive disease (3 or more days' duration or anyone with brawny swelling of the neck):

80,000 to 120,000 units.

DILUTION

Each 1 mL should be diluted with 19 mL D5W or NS and given as an infusion. Warm to 32° to 35° C (90° to 95° F).

Storage:

Refrigerate before dilution.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

To be given as a slow IV infusion, 1 mL/min. Titrate carefully to patient reaction.

ACTIONS

A sterile solution of purified antitoxic substances prepared from the blood serum of horses immunized against diphtheria toxin. Neutralizes the toxins produced by *Corynebacterium diphtheriae*.

INDICATIONS AND USES

Passive transient protection against or treatment of patients with clinical symptoms of diphtheria.

CONTRAINDICATIONS

Hypersensitivity to horse serum unless only treatment available for a life-threatening situation. Several techniques including preload of antihistamines and/or desensitization may be considered (see literature).

PRECAUTIONS

In the United States, diphtheria antitoxin may be obtained from the CDC diphtheria duty officer. The CDC phone number is 1-404-639-3311. Read drug literature supplied with antitoxin completely before use. Essential to evaluate symptoms and individual status of each patient. ■ Determine patient response to any previous injections of serum of any type and history of any allergic-type reactions. ■ Hospitalize patient if possible. ■ If diphtheria is suspected, bacteriologic confirmation of the disease is not necessary to initiate treatment. Begin treatment as soon as possible. Each hour delay increases dosage requirements and decreases effectiveness.

Monitor:

Test every patient without exception for sensitivity to horse serum (1-mL vial of 1:10 dilution horse serum supplied). Conjunctival test and skin test recommended for maximum safety.

Conjunctival test:

Instill 1 drop 1:10 horse serum in conjunctival sac for adults (1 drop 1:100 dilution for pediatric patients). Itching, redness, burning, and/or lacrimation within 30 minutes is a positive reaction. A drop of normal saline in the opposite eye is used as a control and should be asymptomatic. Reverse adverse effects of positive reaction with 1 drop epinephrine ophthalmic solution.

Skin test:

Inject 0.1 mL of 1:100 horse serum intradermally. In patients with a history of allergies use 0.05 mL of a 1:1,000 solution. A like injection of normal saline can be used as a control. An urticarial wheal surrounded by a zone of erythema is a positive reaction. Compare in 20 minutes.

Other testing methods may be used. Use at least two. ■ Continue treatment until all symptoms controlled or bacteriologic confirmation of another disease entity confirmed. ■ Use of full therapeutic doses of antimicrobial agents recommended in conjunction with diphtheria antitoxin. ■ All contacts must be evaluated. Prophylactic antibiotics and immunization may be indicated. ■ See Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

Concomitant use of **antihistamines** may interfere with sensitivity tests.

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse. Serum sickness may occur. Usually appears in 7 to 12 days. Local pain, local erythema, and urticaria without systemic reaction can occur.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Treat anaphylaxis immediately. Epinephrine and diphenhydramine, oxygen, vasopressors (dopamine), corticosteroids, and ventilation equipment must always be available. Salicylates, antihistamines, and/or corticosteroids may be useful in serum sickness. Resuscitate as necessary.

DIPYRIDAMOLE

(dye-peer-**ID**-ah-mohl)
Persantine
Coronary vasodilator
Diagnostic agent
Antiplatelet agent
pH 2.2 to 3.2

USUAL DOSE

Pretreatment:

See Monitor.

Myocardial perfusion imaging:

0.57 mg/kg of body weight equally distributed over 4 minutes (0.142 mg/kg/min). A 70-kg adult would receive a total dose of 39.9 mg (10 mg/min). Maximum dose is 60 mg. Thallium should be injected within 5 minutes following the 4-minute infusion of dipyridamole.

Antiplatelet agent (unlabeled):

250 mg/24 hr as an infusion.

DILUTION

Each 1 mL (5 mg) must be diluted with a minimum of 2 mL D5W, D5/½NS, or D5NS. Total volume should range from a minimum of 20 mL to 50 mL (39.9 mg [8 mL] would be diluted in a minimum of 16 mL for a total infusion of 24 mL; additional diluent can be used to facilitate titration). May not be given undiluted; will cause local irritation.

Antiplatelet agent:

Each 250-mg dose should be diluted with 250 mL D5W (1 mg/mL). Concentration may be increased if larger doses required.

Storage:

Undiluted drug should be stored at CRT and protected from direct light; avoid freezing.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be equally distributed over 4 minutes (0.142 mg/kg/min).

Antiplatelet agent:

10 mg/hr as a continuous infusion. Use of a microdrip (60 gtt/mL) or infusion pump recommended.

ACTIONS

A coronary vasodilator that will cause an increase in coronary blood flow velocity of from 3.8 to 7 times greater than resting velocity. Action may result from the inhibition of adenosine uptake. Peak velocity is reached in 2.5 to 8.7 minutes. Will cause a 20% increase in HR and a mild but significant decrease in systolic and diastolic BP in the supine position. Vital signs may take up to 30 minutes to return to baseline measurements. Used in combination with thallium, visualization shows dilation with sustained enhanced flow of intact vessels, leaving reduced pressure and flow across areas of hemodynamically important coronary vascular constriction. Results achieved are comparable to exercise-induced thallium imaging. Metabolized in the liver. Excreted in bile. Secreted in breast milk.

INDICATIONS AND USES

An alternative to exercise in thallium myocardial perfusion imaging for the evaluation of coronary artery disease in patients who cannot exercise adequately.

Unlabeled uses:

Prophylactic inhibition of platelet aggregation in thromboembolism and myocardial infarction.

CONTRAINDICATIONS

Hypersensitivity to dipyridamole.

PRECAUTIONS

Administered by or under the direction of the cardiologist. ■ Full facilities for treatment of any airway problem, cardiac emergency, or hypersensitivity, including laboratory analysis, must be available. ■ Theophylline (aminophylline) and other emergency drugs must be immediately available. ■ Patients with a history of unstable angina or a history of asthma may be at greater risk; use extreme caution. ■ This drug has caused two fatal myocardial infarctions as well as other serious side effects in a small percentage of patients; clinical information to be gained must be weighed against risk to the patient.

Monitor:

An IV line with a Y-tube or three-way stopcock must be in place. ■ Monitor vital signs continuously during infusion and for at least 15 minutes after or until return to baseline. ■ ECG monitoring using at least 1 chest lead should be continuous. ■ Patient is usually in a supine position, but tests have been conducted in a sitting position. Lower to supine with head tilted down (Trendelenburg) if hypotension occurs.

Maternal/Child:

Category B: safety for use during pregnancy not established. Use only if clearly needed. ■ Temporarily discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Theophylline bronchodilators reverse the effect of dipyridamole on myocardial blood flow. Interferes with dipyridamole-assisted **myocardial perfusion studies.** Withhold bronchodilators for 36 hours before testing.

SIDE EFFECTS

BP lability, chest pain/angina pectoris, dizziness, dyspnea, ECG abnormalities (e.g., extrasystoles, ST-T changes, tachycardia), fatigue, flushing, headache, hypertension, hypotension, nausea, pain (unspecified), paresthesia. Numerous other side effects occur in less than 1% of patients.

Major:

Bronchospasm, cerebral ischemia (transient), fatal and nonfatal myocardial infarction, ventricular fibrillation, ventricular tachycardia (symptomatic) occurred in 0.3% of patients.

ANTIDOTE

Physician will be present throughout test administration. Theophylline (aminophylline) is an adenosine receptor antagonist and will reverse the adenosine-mediated effects of dipyridamole (e.g., angina pectoris, bronchospasm, severe hypotension, ventricular arrhythmias). If bronchospasm or chest pain occurs, administer 50 to 250 mg of theophylline at a rate not to exceed 50 mg over 30 seconds. If symptoms are not relieved by 250 mg of theophylline, sublingual nitroglycerin may be helpful. Persistent chest pain may indicate impending potentially fatal myocardial infarction. If patient condition permits, thallium may be injected and allowed to circulate for 1 minute before injection of theophylline; this will permit initial thallium perfusion imaging before reversal of vasodilatory effects of dipyridamole on coronary circulation. Use head-down supine position for hypotension before administering theophylline. After reversal of vasodilatory action, treat arrhythmias as indicated. Resuscitate as necessary.

DOBUTAMINE HYDROCHLORIDE

(doh-**BYOU**-tah-meen hy-droh-**KLOR**-eyed)
Adrenergic agonist
Inotropic agent
pH 2.5 to 5.5

USUAL DOSE

Pretreatment:

See Monitor.

Dobutamine:

0.5 to 1 mcg/kg/min initially in patients likely to respond to minimum treatment. The usual effective initial dose ranges from 2.5 to 15 mcg/kg of body weight/min. AHA guidelines suggest 2 to 20 mcg/kg/min. Gradually adjust rate at 2- to 10-minute intervals to effect desired response. AHA guidelines recommend titrating so HR does not increase by more than 10% of baseline. Up to 40 mcg/kg/min has been used in some instances; increases potential for toxicity (e.g., myocardial ischemia). U.S. experience in controlled trials does not extend beyond 48 hours of therapy.

PEDIATRIC DOSE

AHA guidelines suggest 2 to 20 mcg/kg/min. Adjust rate to effect desired response; see Maternal/Child.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function, concomitant disease, or other drug therapy. See Drug/Lab Interactions.

DILUTION

Available prediluted in D5W, or each 250-mg (20-mL) vial must be further diluted in at least 50 mL. Any amount of infusion solution desired above 50 mL may be used (250 mg in 1 L equals 250 mcg/mL; 250 mg in 500 mL equals 500 mcg/mL; 250 mg in 250 mL equals 1,000 mcg/mL). Adjust to fluid requirements of the patient. **Compatible** with D5W, D10W, D5/½NS, D5NS, D5/Isolyte M, LR, D5LR, Normosol-M in D5W, 20% Osmitrol in water, NS, or sodium lactate.

Filters:

No data available from manufacturer. Another source suggests no significant drug loss through a 0.22-micron cellulose ester membrane filter.

Storage:

Store premixed bags and vials at CRT; do not freeze. When mixed in infusion solution, use within 24 hours. Pink coloring of solution does not affect potency; will crystallize if frozen.

COMPATIBILITY

Manufacturer states, “Do not administer simultaneously with solutions containing sodium bicarbonate or any other strongly alkaline solution” (e.g., aminophylline, barbiturates). Manufacturer recommends not using other drugs as additives, not using in conjunction with other agents, and not using with diluents containing both sodium bisulfate and ethanol.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of an infusion pump is recommended. Rate of infusion in mL/hr may be calculated using the following formula:

Rate (mL/hr) = [Dose (mcg/kg/min) × Weight (kg) × 60 min/hr] ÷ Final concentration (mcg/mL)

Slowly titrate to desired response. May take up to 10 minutes to achieve peak effect of a specific dose. Half-life of dobutamine is only about 2 minutes. See Maternal/Child.

ACTIONS

A synthetic catecholamine chemically related to dopamine, it is a direct-acting inotropic agent whose primary activity results from stimulation of the beta-receptors. Induces short-term increases in cardiac output by improving stroke volume with minimum increases in rate and BP, minimum rhythm disturbances, and some decrease in systemic vascular resistance. Effectiveness may decrease over time. Most use is short-term. Onset of action is 1 to 2 minutes; however, as much as 10 minutes may be required to obtain the peak effect. Has a very short duration of action. Half-life is 2 minutes; may be up to 5 minutes in preterm infants. Metabolized in the liver and other tissues. Metabolites are primarily excreted in the urine.

INDICATIONS AND USES

Short-term inotropic support in cardiac decompensation due to depressed contractility resulting from either organic heart disease or cardiac surgical procedures.

CONTRAINDICATIONS

Hypersensitivity to any components (contains sulfites), idiopathic hypertrophic subaortic stenosis, shock without adequate fluid replacement. ■ Solutions containing dextrose may be contraindicated in patients with known allergy to corn or corn products.

PRECAUTIONS

Use extreme caution in myocardial infarction; increases in contractile force and HR may increase myocardial ischemia and size of infarction. ■ Precipitous hypotension occurs rarely; usually reverses with a decrease in rate of administration; see Antidote. ■ Use with caution in patients with atrial fibrillation; facilitates atrioventricular conduction, placing patients at risk for developing rapid ventricular response. Use digoxin preparation before starting dobutamine in patients with atrial fibrillation with rapid ventricular response. ■ May precipitate or exacerbate ventricular ectopic activity but has rarely caused ventricular tachycardia. ■ Reactions suggestive of hypersensitivity have been reported. ■ Contains sulfites; use caution in patients with allergies. ■ Ineffective if marked mechanical obstruction (e.g., severe valvular aortic stenosis) is present. ■ Use for long-term treatment of CHF has been associated with increased risks of hospitalization and death. ■ Solutions containing dextrose should be used with caution in patients with known or subclinical or overt diabetes mellitus.

Monitor:

Correct hypovolemia and electrolyte disturbances (e.g., hypokalemia, hypomagnesemia) before initiating treatment. ■ Continuous monitoring of ECG, BP, and HR required. Measure pulmonary wedge pressure, central venous pressure, and cardiac output if possible. ■ May cause significant increase in BP or HR, especially systolic pressure. Patients with pre-existing hypertension may be at increased risk of developing an increased pressor response. ■ Monitor for changes in fluid balance (input/output), electrolytes, and acid-base balance. ■ Monitor for S/S of possible hypersensitivity reactions (e.g., bronchospasm, eosinophilia, fever, rash). ■ See Drug/Lab Interactions.

Maternal/Child:

Use only if benefits outweigh risks. ■ Use caution in breast-feeding. ■ Increases cardiac output and systemic BP in pediatric patients of every age-group, usually at infusion rates that are lower than those that cause significant tachycardia. Less effective than dopamine in premature neonates.

Elderly:

Lower-end initial doses may be indicated; see Dose Adjustments. ■ Differences in response compared to younger adults not identified, but greater sensitivity of some elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

May be ineffective if **beta-blocking drugs** have been given. ■ Produces higher cardiac output and lower pulmonary wedge pressure when given concomitantly with **nitroprusside sodium** than when either drug is used alone. ■ May cause severe hypertension with **oxytocic drugs or guanethidine**. ■ Pressor response increased with **tricyclic antidepressants** and **rauwolfia alkaloids** (e.g., reserpine); may cause hypertension. ■ Use with caution in patients taking **MAO inhibitors**; prolonged hypertension may result from concurrent use.

SIDE EFFECTS

Anginal pain, chest pain, headache, hypertension, hypokalemia, hypotension, increased ventricular ectopic activity, myocardial ischemia, nausea, palpitations, phlebitis, shortness of breath, stress cardiomyopathy, tachycardia. Hypersensitivity reactions (e.g., bronchospasm, eosinophilia, fever, skin rash) have been reported. Local inflammatory changes may occur with infiltration.

Overdose:

In addition to all of the above, overdose may cause anorexia, anxiety, excessive hypertension or hypotension, myocardial ischemia, tremor, ventricular tachycardia, and/or fibrillation, vomiting.

ANTIDOTE

Notify physician of all side effects. Many will resolve with a reduction in rate of administration. Decrease infusion rate and notify physician immediately if number of PVCs increases or there is a marked increase in pulse rate or BP. For accidental overdose, reduce rate or temporarily discontinue until condition stabilizes. Maintain a patent airway with adequate oxygenation and ventilation. Meticulously monitor and maintain patient's VS, blood gases, serum electrolytes, etc. Forced diuresis, peritoneal dialysis, hemodialysis, or charcoal hemoperfusion have not been established as beneficial for overdosage. Treat ventricular tachyarrhythmias with propranolol (Inderal) or lidocaine. Hypertension usually responds to a reduced rate or temporarily discontinuing dobutamine. Reduce rate or discontinue dobutamine if hypotension occurs. May require treatment with vasopressors (e.g., dopamine, norepinephrine). See Precautions.

DOCETAXEL BBW

(doh-seh-**TAX**-ell)
Taxotere
Antineoplastic agent (taxane)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication for all patients except those with castration-resistant prostate cancer:

Must be pretreated with oral corticosteroids to reduce the incidence and severity of fluid retention and hypersensitivity reactions. Usual regimen is dexamethasone 8 mg PO twice a day for 3 days. Begin 1 day before each docetaxel infusion.

Premedication for hormone-refractory prostate cancer:

Administer oral dexamethasone 8 mg at 12 hours, 3 hours, and 1 hour before each docetaxel infusion (another steroid, prednisone, is part of the combination therapy).

Breast cancer:

60 to 100 mg/M^2 as an infusion. Repeat every 3 weeks.

Combination therapy for adjuvant treatment of operable node-positive breast cancer:

75 mg/M^2 as an infusion. Administer 1 hour after doxorubicin 50 mg/M^2 and cyclophosphamide 500 mg/M^2. Repeat every 3 weeks for 6 cycles. Prophylactic G-CSF (e.g., filgrastim) may be used to mitigate the risk of hematologic toxicity. See doxorubicin and cyclophosphamide monographs.

Prostate cancer (castration-resistant):

75 mg/M^2 as an infusion. Repeat every 3 weeks. Prednisone 5 mg PO twice daily is administered continuously throughout treatment. See Premedication.

Non–small-cell lung cancer (NSCLC) in chemotherapy-naïve patients:

75 mg/M^2 as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M^2 as an infusion over 30 to 60 minutes. Repeat regimen every 3 weeks. ***Premedicate*** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph.

NSCLC after failure of prior chemotherapy:

75 mg/M^2 as an infusion. Repeat every 3 weeks. Larger doses increased toxicity, infection, and treatment-related mortality.

Gastric adenocarcinoma:

75 mg/M^2 as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M^2 as an

infusion over 1 to 3 hours (both on Day 1 only). ***Premedicate*** with antiemetics and hydration as required for cisplatin administration; see cisplatin and fluorouracil monographs. Follow the cisplatin infusion with fluorouracil 750 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil dose for 4 more 24-hour infusions (total of 5 days). Repeat regimen every 3 weeks. In the study, G-CSF (filgrastim) was recommended during the second and/or subsequent cycles to prevent or attenuate febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days.

Induction chemotherapy followed by radiotherapy for treatment of inoperable, locally advanced squamous cell cancer of the head and neck (SCCHN):

75 mg/M² as an infusion over 1 hour. Follow immediately with cisplatin 75 mg/M² as an infusion over 1 hour (both on Day 1 only). ***Premedicate*** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph. Follow the cisplatin infusion with fluorouracil 750 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil for four more 24-hour infusions (total of 5 days). See fluorouracil monograph. Repeat regimen every 3 weeks for a total of four cycles. Prophylactic antibiotics were used in clinical studies. In the study, G-CSF (filgrastim) was recommended during the second and/or subsequent cycles to prevent or attenuate febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days. Following chemotherapy, patients should receive radiotherapy.

Induction chemotherapy followed by chemoradiotherapy for treatment of locally advanced (unresectable, low surgical cure, or organ preservation) SCCHN:

75 mg/M² as an infusion over 1 hour. Follow with cisplatin 100 mg/M² as a 30-minute to 3-hour infusion (both on Day 1 only). ***Premedicate*** with antiemetics and hydration as required for cisplatin administration; see cisplatin monograph. Follow the cisplatin infusion with fluorouracil 1,000 mg/M² as an infusion equally distributed over 24 hours. Repeat fluorouracil for three more 24-hour infusions (total of 4 days). See fluorouracil monograph. Repeat regimen every 3 weeks for 3 cycles. Prophylactic antibiotics were used in clinical studies. In the study, G-CSF (filgrastim) was recommended during the second and/or subsequent cycles to prevent or attenuate febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days. Following chemotherapy, patients should receive chemoradiotherapy.

Treatment of ovarian cancer (unlabeled):

60 to 75 mg/M² as an infusion in combination with carboplatin. Repeat every 3 weeks.

Metastatic bladder cancer (unlabeled):

100 mg/M² every 3 weeks as a single agent or 35 mg/M² on Days 1 and 8 of a 21-day cycle in combination with gemcitabine and cisplatin. Administer for at least 6 cycles or until disease progression or unacceptable toxicity.

Treatment of esophageal cancer (unlabeled):

75 mg/M^2 as a 1-hour infusion every 21 days used in combination with fluorouracil and cisplatin.

DOSE ADJUSTMENTS

All diagnoses:

Withhold therapy if neutrophils below 1,500/mm^3 or platelets below 100,000 cells/mm^3. A 25% reduction in the dose of docetaxel is recommended during subsequent cycles following severe neutropenia (less than 500/mm^3) lasting 7 days or more, febrile neutropenia, or a Grade 4 infection. ■ Withhold therapy if bilirubin is greater than the ULN or if AST and/or ALT is greater than 1.5 times the ULN concomitant with alkaline phosphatase greater than 2.5 times the ULN. ■ Discontinue therapy in patients who develop Grade 3 or higher peripheral neuropathy. ■ Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ Consider additional dose adjustments when docetaxel is given in combination with other chemotherapeutic agents. ■ See Precautions and Drug/Lab Interactions.

Breast cancer:

Reduce dose to 75 mg/M^2 for patients initially dosed at 100 mg/M^2 who experience febrile neutropenia, severe neutropenia (neutrophils below 500/mm^3 for more than 1 week), severe or cumulative cutaneous reaction, or severe peripheral neuropathy. Further reduce to 55 mg/M^2 or discontinue docetaxel if any of the previously listed reactions persist. ■ Patients receiving the lower dose of docetaxel (60 mg/M^2) may have the dose increased gradually if lower dose was well tolerated. ■ Discontinue therapy in patients who develop Grade 3 or greater peripheral neuropathy.

Combination therapy for adjuvant treatment of operable node-positive breast cancer:

Patients who experience febrile neutropenia should receive G-CSF (e.g., filgrastim) in all subsequent cycles. Patients who continue to experience this reaction should remain on G-CSF and have their docetaxel dose decreased to 60 mg/M^2. ■ Reduce docetaxel dose to 60 mg/M^2 in patients who experience Grade 3 or 4 stomatitis. ■ Reduce docetaxel dose from 75 to 60 mg/M^2 in patients who experience severe or cumulative cutaneous reactions or moderate neurosensory signs and/or symptoms. If side effects persist at the lower dose, discontinue therapy.

Prostate cancer:

Reduce docetaxel dose from 75 to 60 mg/M^2 in patients who experience dose-limiting toxicities (e.g., febrile neutropenia, neutrophils less than 500 cells/mm^3 for more than 1 week, severe or cumulative cutaneous reactions, or moderate neurosensory signs and/or symptoms). If side effects persist at the lower dose, discontinue therapy.

Non–small-cell lung cancer after failure of prior chemotherapy:

In NSCLC patients who experience either febrile neutropenia, neutrophils less than 500 cells/mm^3 for more than 1 week, severe or cumulative cutaneous reactions, or other Grade 3 or 4 nonhematologic toxicities, withhold docetaxel until resolution of toxicity, then resume at 55 mg/M^2. ■ Discontinue therapy in patients who develop Grade 3 or greater peripheral neuropathy.

Non–small-cell lung cancer (NSCLC) in chemotherapy-naïve patients:

Reduce dose to 65 mg/M^2 in patients whose nadir of platelet count during the previous course of therapy was less than 25,000 cells/mm^3, in patients who experienced febrile neutropenia, and in patients with serious nonhematologic toxicities. Dose may be further reduced to 50 mg/M^2 as indicated. See cisplatin monograph for cisplatin dose adjustments.

Gastric adenocarcinoma and head and neck cancer:

Patients who experience febrile neutropenia, documented infection with neutropenia, or neutropenia lasting more than 7 days should receive G-CSF (e.g., filgrastim) in all subsequent cycles. Patients who continue to experience this reaction should remain on G-CSF and have their docetaxel dose decreased to 60 mg/M^2. Reduce dose further to 45 mg/M^2 if subsequent episodes of complicated neutropenia occur. ■ Reduce docetaxel dose from 75 to 60 mg/M^2 in patients who experience Grade 4 thrombocytopenia. ■ Hold subsequent cycles of docetaxel until neutrophils recover to a level of greater than 1,500 cells/mm^3 and platelets recover to a level greater than 100,000 cells/mm^3. ■ If the previously mentioned toxicities persist, discontinue therapy. ■ Additional dose adjustments are outlined in the following chart.

Additional Recommended Dose Adjustments for Toxicities in Gastric Adenocarcinoma or Head and Neck Cancer Patients Treated With Docetaxel in Combination With Cisplatin and Fluorouracil

Toxicity	Dose Adjustment
Diarrhea Grade 3	**First episode:** Reduce 5-FU dose by 20%. **Second episode:** Reduce docetaxel dose by 20%.
Diarrhea Grade 4	**First episode:** Reduce docetaxel and 5-FU doses by 20%. **Second episode:** Discontinue treatment.
Stomatitis/mucositis Grade 3	**First episode:** Reduce 5-FU dose by 20%. **Second episode:** Stop 5-FU only at all subsequent cycles. **Third episode:** Reduce docetaxel dose by 20%.
Stomatitis/mucositis Grade 4	**First episode:** Stop 5-FU only at all subsequent cycles. **Second episode:** Reduce docetaxel dose by 20%.
AST/ALT >2.5 to ≤5 × ULN and AP ≤2.5 × ULN, or AST/ALT >1.5 to ≤5 × ULN and AP >2.5 to ≤5 × ULN	Reduce docetaxel dose by 20%.
AST/ALT >5 × ULN and/or AP >5 × ULN	Discontinue docetaxel.
Peripheral neuropathy Grade 2	Reduce cisplatin dose by 20%.
Peripheral neuropathy Grade 3	Discontinue cisplatin treatment.
Ototoxicity Grade 3	Discontinue cisplatin treatment.
Rise in SCr ≥ Grade 2 (>1.5 × normal value) despite adequate rehydration	Determine CrCl before each subsequent cycle and consider the following dose reductions as outlined below.
CrCl ≥60 mL/min	Full dose of cisplatin given. Repeat CrCl before each treatment cycle.
CrCl >40 and <60 mL/min	Reduce dose of cisplatin by 50% at subsequent cycle. If CrCl was >60 mL/min at end of cycle, give full dose at the next cycle. If no recovery observed, omit cisplatin from the next treatment cycle.
CrCl <40 mL/min	Omit dose of cisplatin for **that treatment cycle only.** Discontinue cisplatin if CrCl remains at <40 mL/min. Reduce cisplatin dose by 50% if CrCl was >40 and <60 mL/min at end of cycle. Give full cisplatin dose if CrCl is >60 mL/min at end of cycle.
Plantar-palmar toxicity Grade 2 or greater	Discontinue fluorouracil until recovery, then reduce fluorouracil dose by 20%.
Other greater than Grade 3 toxicities except alopecia (can be permanent) and anemia	Delay 5-FU chemotherapy (for a maximum of 2 weeks from the planned date of infusion) until resolution to ≤Grade 1. If medically appropriate, resume treatment.

DILUTION

Specific techniques required; see Precautions. If docetaxel or diluted solution comes into contact with skin, immediately and thoroughly wash with soap and water. If docetaxel or diluted solution comes into contact with mucosa, immediately and thoroughly wash with water.

Available in multiple formulations, in ***several concentrations, and as both single-use and multiple-use products; read label carefully.*** Formulations are ***NOT*** interchangeable in a dose. ***Do not use the two-vial formulation (injection concentrate and diluent [contains 13% ethanol in water for injection]) with the one-vial formulation. Read prescribing information carefully for product-specific dilution, storage, and stability information.***

Single-bottle formulations (generic and Taxotere):

Available in 10 mg/mL and 20 mg/mL concentrations in multiple sizes. Manually rotate to mix thoroughly. Requires no initial dilution and is ready to add to an infusion solution; ***read label carefully*** to avoid overdose. Allow required number of vials to stand at room temperature for 5 minutes if refrigerated. Using a 21-gauge needle (product specific), withdraw required amount of docetaxel and inject via a single injection into a 250-mL infusion bag or bottle of NS or D5W; ***see all formulations below.*** Manually rotate to mix thoroughly.

Two-vial formulation (generic):

Available in 20 mg/0.5 mL or in 80 mg/2 mL vials ***(concentration is 2 times greater than the single-bottle formulation; read label carefully).*** Allow required number of vials to stand at room temperature for 5 minutes if refrigerated. Reconstitute the appropriate vial (20 or 80 mg) with the entire contents of the diluent vial. Resulting concentration is 10 mg/mL. Mix well by repeated inversions for at least 45 seconds. ***Do not shake.*** Allow to stand until most of the foam dissipates. After this initial reconstitution, withdraw the required amount of 10 mg/mL concentrate and inject into a 250-mL bag or bottle of NS or D5W; ***see all formulations below.***

All formulations:

Final dilution should be in glass or polypropylene bottles or polypropylene or polyolefin plastic bags for infusion. Thoroughly mix the infusion by manual rotation. Should be administered through polyethylene-lined administration sets. Desired concentration should be between 0.3 and 0.74 mg/mL (100 mg in 250 mL = 0.4 mg/mL). If a dose greater than 200 mg is required, use a larger volume of NS or D5W so that a final concentration of 0.74 mg/mL is not exceeded. Solution should be clear.

Filters:

Not required.

Storage:

Storage requirements and stability are brand specific; check prescribing information. Some products may be stored at RT. Others require refrigeration. Docetaxel injection infusion solution is supersaturated and may therefore crystallize over time. If crystals appear, the solution must no longer be used and should be discarded.

Most formulations:

Most formulations when fully diluted in NS or D5W should be used within 4 hours (including the 1-hour infusion time). **Taxotere** (one-vial formulation) is stable for 6 hours (including the 1-hour infusion time). At least one generic product is available as a multiple-dose vial that is stable for 28 days when refrigerated.

COMPATIBILITY

Leaches out plasticizers, including DEHP, from PVC infusion bags and administration sets. Use glass or polypropylene bottles or plastic (polypropylene or polyolefin) bags and polyethylene-lined administration sets to minimize patient exposure to leached DEHP. Do not allow concentrate to come into contact with plasticized PVC equipment or devices used to prepare and administer solutions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose, properly diluted, equally distributed over 1 hour. Room temperature should be cool and lighting should be low.

ACTIONS

An antineoplastic. A novel, semisynthetic, antimicrotubule agent derived from the needles of the yew plant. It inhibits cancer cell division. Microtubules assemble and disassemble during the cell cycle. Docetaxel promotes assembly and blocks disassembly of microtubules, preventing the cancer cells from dividing. The end result is cancer cell death. Highly protein bound. Metabolized in the liver by CYP3A4, an isoenzyme of the P_{450} family. Half-life is 11.1 hours. Eliminated primarily through feces and, to a lesser extent, urine and bile.

INDICATIONS AND USES

Treatment of locally advanced or metastatic breast cancer after failure of prior chemotherapy. ■ In combination with doxorubicin and cyclophosphamide for adjuvant treatment of operable node-positive breast cancer. ■ As a single agent in the treatment of locally advanced or metastatic NSCLC after failure of platinum-based chemotherapy (e.g., cisplatin). ■ In combination with cisplatin for treatment of patients with unresectable, locally advanced, or metastatic NSCLC who have not previously received chemotherapy for this condition. ■ In combination with prednisone for the treatment of castration-resistant metastatic prostate cancer. ■ In combination with cisplatin and fluorouracil for the treatment of advanced gastric adenocarcinoma, including adenocarcinoma of the gastroesophageal junction, in patients who have not received prior chemotherapy for advanced disease. ■ In combination with cisplatin and fluorouracil for induction therapy of locally advanced SCCHN. Following chemotherapy, patients should receive radiotherapy.

Unlabeled uses:

Treatment of metastatic bladder cancer, esophageal cancer, ovarian cancer, soft tissue sarcomas, and adenocarcinomas of unknown primary site; consult literature.

CONTRAINDICATIONS

Baseline neutropenia less than 1,500 cells/mm^3. ■ History of hypersensitivity reactions to docetaxel or other drugs formulated with polysorbate 80. ■ Severe impaired liver function. In the United States, docetaxel is not recommended for patients with a bilirubin above the ULN or in patients with ALT and/or AST greater than 1.5 times the ULN range and increases in alkaline phosphatase greater than 2.5 times the ULN range; see Precautions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be readily available. ■ Incidence of treatment-related mortality increased in patients with abnormal liver function, in patients receiving higher doses, and in patients with NSCLC and a history of prior treatment with platinum-based chemotherapy who receive docetaxel as a single agent at a dose of 100 mg/M^2. ■ Patients with elevations of bilirubin or abnormalities of transaminase concurrent with alkaline phosphatase are at increased risk for the development of Grade 4 neutropenia, febrile neutropenia, infections, severe thrombocytopenia, severe stomatitis, severe skin toxicity, and toxic death. ■ Not recommended for patients with hepatic impairment; see Contraindications. Risk of toxicity and death is significant. Patients with isolated elevations of transaminases greater than 1.5 times the ULN have a higher rate of neutropenia Grade 4 but not of toxic death. Alcohol content of some products should be considered if given to patients with hepatic impairment. ■ Reversible myelosuppression is the major dose-limiting toxicity of docetaxel. The median time to nadir was 7 days, and the median duration of severe neutropenia (fewer than 500 cells/mm^3) was 7 days. ■ Febrile neutropenia occurred in patients dosed at 100 mg/M^2 but was uncommon in patients dosed at 60 mg/M^2. Hematologic responses, febrile reactions and infections, and rates of septic death for different regimens are dose related. ■ Enterocolitis and neutropenic colitis (typhlitis) have occurred despite the coadministration of G-CSF. Use caution in patients with neutropenia, particularly in patients at risk for developing GI complications. ■ Severe hypersensitivity reactions characterized by generalized rash/erythema, hypotension and/or bronchospasm or, rarely, fatal anaphylaxis have been reported. ■ Patients who have previously experienced a hypersensitivity reaction to paclitaxel may develop a hypersensitivity reaction to docetaxel that may include severe or fatal reactions such as anaphylaxis. ■ In addition to myelosuppression and hypersensitivity reactions, localized erythema of the extremities with edema followed by desquamation, severe fluid retention, severe neurosensory symptoms (e.g., dysesthesia, pain, paresthesia), and severe asthenia (usually in metastatic breast cancer patients) has been reported. ■ Severe fluid retention may occur despite premedication with dexamethasone. ■ Use with caution in patients with pleural effusion; may be exacerbated by docetaxel-induced fluid retention. ■ Second primary malignancies, notably acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), non-Hodgkin lymphoma (NHL), and renal cancer have been reported in patients treated with docetaxel-containing regimens. May occur months to years after docetaxel-containing therapy. ■ Cystoid macular edema (CME) has been reported; see Monitor. ■ Cases of intoxication have been reported with some formulations of docetaxel due to the alcohol content. Alcohol content may affect the CNS and should be considered in patients in whom alcohol intake should be avoided or minimized. May affect ability to drive or use machinery immediately after the infusion. ■ When administering combination therapy, consult all appropriate drug monographs for relevant information. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline CBC with differential and platelets; monitor frequently during therapy and before each dose. See Dose Adjustments. ■ Obtain baseline bilirubin, AST, ALT, and alkaline phosphatase; monitor as indicated during therapy (recommended before each dose). ■ Obtain baseline and periodic renal function, if indicated. ■ Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; discontinue injection; use another vein. ■ Obtain baseline vital signs; monitor during and after infusion. ■ Monitor for hypersensitivity reactions, especially during the first and second infusions; may occur within minutes. Discontinue docetaxel if reaction is severe. Hypersensitivity reactions may occur even in patients premedicated with dexamethasone. ■ Closely monitor patients with a previous history of hypersensitivity to paclitaxel during initiation of docetaxel therapy. ■ Monitor for localized erythema of the palms of the hands and soles of the feet with or without desquamation. Skin eruptions generally occur within 1 week after docetaxel infusion, resolve before the next infusion, and are not disabling. However, severe reactions have been reported. A reduced dose may be indicated if severe. ■ Monitor for fluid retention. Salt restriction and treatment with oral diuretics may be indicated. S/S of severe fluid retention include abdominal distension (severe), cardiac tamponade, dyspnea at rest, peripheral or generalized edema, pleural effusion. ■ Observe for signs of peripheral neurotoxicity (e.g., neurosensory symptoms such as dysesthesia, pain, paresthesia, and peripheral motor neuropathy manifested primarily as distal extremity weakness); docetaxel may need to be discontinued; see Dose Adjustments. In patients with gastric adenocarcinoma or SCCHN, a baseline neurologic exam is recommended. Repeat every 2 cycles and at the end of treatment; see Dose Adjustments. ■ Monitor patients for the onset of any GI toxicity. Enterocolitis and neutropenic enterocolitis may develop at any time and can lead to death as early as the first day of symptom onset. ■ Observe for signs of infection. Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. Monitor patients receiving docetaxel (Taxotere), cisplatin, fluorouracil (5-FU) combination therapy closely for febrile neutropenia and/or neutropenic infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3); see Dose Adjustments. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for signs of existing or developing impaired vision. A prompt comprehensive ophthalmologic exam is indicated. If CME is diagnosed, discontinue docetaxel. ■ Hematologic follow-up required due to risk of delayed second primary malignancies.

Patient Education:

Avoid pregnancy. Females of reproductive potential should use effective contraception during treatment and for 6 months after the last dose of docetaxel. Male patients with female partners of reproductive potential should use effective contraception during treatment and for 3 months after the last dose. ■ May impair fertility in males of reproductive potential. ■ Review of monitoring requirements (e.g., CBCs, liver function tests) and adverse events before therapy imperative. ■ Pretreatment with dexamethasone as prescribed is imperative. ■ Report pain or burning at injection site and any unusual or unexpected symptoms or side effects as soon as possible (e.g., constipation, diarrhea, excessive tearing, fatigue, fever, hair loss [cases of permanent hair loss have been reported], hypersensitivity reaction [e.g., difficulty breathing, itching, rash], infusion site reaction, irregular and/or rapid heartbeat, nausea and vomiting, shortness of breath, swelling of feet and legs, weight gain, change in vision). ■ Promptly report new or worsening symptoms of GI toxicity. ■ Immediately report myalgia or cutaneous or neurologic reactions. ■ Review all medications (prescription and nonprescription) and allergies with nurse and/or physician. ■ Medication may contain alcohol. May affect ability to drive or operate machinery immediately after infusion. ■ See Appendix D, p. 1311. ■ Obtain name and telephone number of a contact person for emergencies, questions, or problems. ■ Seek resources for counseling or supportive therapy. ■ Risk of second primary malignancies requires hematologic follow-up. Changes in blood counts due to leukemia and other blood disorders may occur years after treatment.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. ■ Avoid breast-feeding during treatment and for 1 week after the last dose of docetaxel. ■ Effectiveness in pediatric patients as monotherapy or in combination have not been established. The overall safety profile of docetaxel in pediatric patients receiving monotherapy or combination treatment with cisplatin and 5-fluorouracil was consistent with the known safety profile in adults. Has been used in a small number of pediatric patients; see manufacturer's prescribing information. ■ The alcohol content of docetaxel should be taken into account when given to pediatric patients.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ May be at increased risk for developing side effects such as anemia, anorexia, diarrhea, dizziness, febrile neutropenia, infections, lethargy, nail changes, peripheral edema, stomatitis, and weight loss. ■ Monitor hepatic function carefully.

DRUG/LAB INTERACTIONS

A substrate of CYP3A4. Metabolism may be modified by concomitant administration of other medications that induce, inhibit, or are metabolized by CYP3A4 (e.g., cyclosporine, phenytoin, phenobarbital, tacrolimus, and many others). ■ Metabolism inhibited and serum levels increased with **strong CYP3A4 inhibitors** (e.g., imidazole antifungals [e.g., itraconazole, voriconazole], protease inhibitors [e.g., atazanavir, indinavir, nelfinavir, ritonavir, saquinavir], clarithromycin, and nefazodone). Avoid use. A pharmacokinetic study suggests considering a 50% dose reduction of docetaxel if coadministration of a strong CYP3A4 inhibitor is required; monitor closely for toxicity.

- Docetaxel clearance is not affected by coadministration of **prednisone, dexamethasone, fluorouracil, cyclophosphamide, doxorubicin**, or **cisplatin**.
- Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Generally reversible but can be fatal. The most common side effects across all indications are alopecia, anemia, anorexia, asthenia, constipation, diarrhea, dysgeusia, dyspnea, febrile neutropenia, fluid retention (e.g., ascites, edema, pericardial effusion, pleural effusion), hypersensitivity reactions (e.g., back pain, chest tightness, chills, drug fever, dyspnea, flushing, hypotension, pruritus, rash), infection, mucositis, myalgia, nail disorders, nausea, neuropathy, neutropenia, pain, skin reactions, thrombocytopenia, and vomiting. Increased incidence of bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia) and/or severity of side effects is dose dependent and can be dose limiting. The most serious adverse reactions are alcohol intoxication, asthenia, cutaneous reactions, enterocolitis and neutropenic colitis, eye disorders, fluid retention, hematologic toxicity, hepatotoxicity, hypersensitivity, neurologic reactions, second primary malignancies, and toxic deaths. Abdominal pain; acute myeloid leukemia and myelodysplastic syndrome; acute pulmonary edema; acute respiratory distress syndrome; alcohol intoxication; altered hearing; amenorrhea; arthralgia; bleeding episodes; cardiac arrhythmias; CHF; colitis; confusion; conjunctivitis; cough; cutaneous reactions (e.g., localized rash on hands, feet, arms, face, thorax; erythema multiforme; severe hand and foot syndrome; Stevens-Johnson syndrome; toxic epidermal necrolysis); diarrhea; DIC (often in association with sepsis or multiorgan failure); dizziness; enteritis; esophagitis/dysphagia/odynophagia; eye disorders (e.g., CME); fatigue; fever with or without infection; gastrointestinal pain and cramping; heartburn; hepatitis (sometimes fatal, primarily in patients with pre-existing liver disease); hypotension; increased ALT, AST, and bilirubin; infusion site reactions; interstitial pneumonia; lethargy; lymphedema; myocardial ischemia; neurosensory symptoms (e.g., dysesthesia, pain, paresthesia); neutropenic infection; paresthesias (e.g., pain, burning sensation); perforation of the large intestine; renal insufficiency; seizures or transient loss of consciousness; stomatitis; taste perversion; tearing; vasodilation.

Overdose:

Bone marrow suppression, mucositis, peripheral neurotoxicity.

Post-Marketing:

Acute pulmonary edema, acute respiratory distress syndrome/pneumonitis, alopecia (permanent), anaphylactic shock, atrial fibrillation, bullous eruptions, chest pain, cutaneous lupus erythematosus, cystoid macular edema, deep vein thrombosis, dehydration, diffuse pain, disseminated intravascular coagulation (DIC) (often in association with sepsis or multiorgan failure), duodenal ulcer, dyspnea, ECG abnormalities, esophagitis, gastrointestinal perforation, GI hemorrhage, hearing disorders/loss, hepatitis, hyponatremia, ileus, interstitial lung disease, interstitial pneumonia, intestinal obstruction, ischemic colitis, lacrimation with or without conjunctivitis, MI, myelodysplastic syndrome, neutropenic enterocolitis, ototoxicity, pulmonary embolism, pulmonary fibrosis, radiation pneumonitis, radiation recall phenomenon, renal failure (most commonly associated with concomitant nephrotoxic drugs), renal insufficiency, respiratory failure, scleroderma-like changes (usually preceded by peripheral lymphedema), seizures, syncopy, tachycardia, thrombophlebitis, transient loss of consciousness, transient visual disturbances.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Most hypersensitivity reactions will subside with temporary discontinuation of docetaxel, and incidence seems to decrease with subsequent doses. Discontinue docetaxel if a severe hypersensitivity reaction occurs. Severe reactions may require epinephrine, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., dexamethasone), or bronchodilators (e.g., albuterol). Patients with a history of a severe hypersensitivity reaction should not be rechallenged. If CME is diagnosed, discontinue docetaxel and initiate appropriate treatment. Consider alternative non-taxane cancer treatment. Neutropenia can be profound. Recovery is generally rapid and spontaneous but may be treated with filgrastim or pegfilgrastim. Severe thrombocytopenia may require platelet transfusions. Severe anemia (less than 8 Gm/dL) may require packed cell transfusions. Serious cutaneous reactions with desquamation (rare), serious fluid retention, persistent febrile neutropenia, severe peripheral neuropathy, or severe liver impairment may require discontinuation of docetaxel. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

DOLASETRON MESYLATE

(dohl-**AH**-seh-tron **MES**-ih-layt)
Anzemet
Antiemetic (5HT$_3$ receptor antagonist)
pH 3.2 to 3.8

USUAL DOSE

Pretreatment:

Obtain baseline electrolytes; see Monitor.

Prevention of postoperative nausea and/or vomiting:

12.5 mg as a single dose 15 minutes before cessation of anesthesia. If prophylaxis fails, a repeat dose should **NOT** be administered as rescue therapy.

Treatment of postoperative nausea and/or vomiting:

12.5 mg as a single dose as soon as nausea or vomiting presents.

PEDIATRIC DOSE

Doses are those recommended for ***pediatric patients 2 to 16 years of age.*** Safety and effectiveness in pediatric patients under 2 years of age not established; see Contraindications and Maternal/Child. Dolasetron solution for injection may be mixed with apple or apple-grape juice for oral administration to pediatric patients. See prescribing information for oral doses.

Prevention of postoperative nausea and/or vomiting:

0.35 mg/kg up to a maximum dose of 12.5 mg as a single dose 15 minutes before cessation of anesthesia. If prophylaxis fails, a repeat dose should **NOT** be administered as rescue therapy.

Treatment of postoperative nausea and/or vomiting:

0.35 mg/kg up to a maximum dose of 12.5 mg as a single dose as soon as nausea or vomiting presents.

DOSE ADJUSTMENTS

No dose adjustments required for the elderly, renal failure, or impaired hepatic function; however, caution and lower-end dosing are suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

IV injection:

A single dose may be given undiluted.

IV infusion:

A single dose may be further diluted up to 50 mL in NS, D5W, D5/½NS, D5LR, LR, or 10% mannitol.

Storage:

Store vials at CRT; protect from light. Stable after dilution at CRT for 24 hours or 48 hours if refrigerated.

COMPATIBILITY

Manufacturer states, “Should not be mixed with other drugs. Flush the infusion line with a **compatible** IV solution before and after administration.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush infusion line before and after administration. May cause bradycardia, severe hypotension, and syncope during or shortly after administration.

IV injection:

A single dose over 30 seconds.

IV infusion:

Administer a single dose over 15 minutes.

ACTIONS

An antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5-HT_3) receptors, similar to granisetron and ondansetron. 5-HT3 receptors are located on the nerve terminals of the vagus in the periphery and centrally in the chemoreceptor trigger zone. By antagonizing these receptors, nausea and vomiting are prevented. Rapidly and completely metabolized to its active metabolite, hydrodolasetron. Maximum concentration of hydrodolasetron occurs 0.6 hours after injection or infusion. Widely distributed in the body, 69% to 77% bound to plasma protein. Eliminated by multiple routes. Hydrodolasetron is partially metabolized. Average half-life is 7.3 hours. Excreted in urine and feces as unchanged drug and metabolites. Not known if dolasetron is secreted in breast milk.

INDICATIONS AND USES

Prevention of postoperative nausea and vomiting in adults and pediatric patients 2 years of age and older when indicated. When prophylaxis has failed, a repeat dose should not be initiated as rescue therapy. ■ Treatment of postoperative nausea and/or vomiting in adults and pediatric patients 2 years of age and older.

CONTRAINDICATIONS

Known hypersensitivity to dolasetron. ■ Contraindicated in adult and pediatric patients for the prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy because of risk for dose-dependent QTc prolongation.

PRECAUTIONS

Prolongs the QT interval in a dose-dependent fashion. Torsades de pointes has been reported. Avoid use in patients with congenital long QT syndrome, hypokalemia, or hypomagnesemia. ■ Has been shown to cause dose-dependent prolongation of the PR and QRS interval. Second- or third-degree atrioventricular block, cardiac arrest, and serious ventricular arrhythmias, including fatalities in both adult and pediatric patients, have been reported. At particular risk are patients with underlying structural heart disease, pre-existing conduction system abnormalities, sick sinus syndrome, atrial fibrillation with slow ventricular response, or myocardial ischemia; elderly patients; or patients receiving drugs known to prolong the PR interval (such as verapamil) and QRS interval (e.g., flecainide [Tambocor] or quinidine). Use with caution and monitor ECG. Avoid use in patients with or at risk for complete heart block unless they have an implanted pacemaker. ■ Use with caution in patients who have or may develop prolongation of cardiac conduction intervals, particularly QT intervals (e.g., patients with hypokalemia, hypomagnesemia, congenital QT syndrome, cumulative high-dose anthracycline therapy [e.g., doxorubicin (Adriamycin)], patients taking diuretics with potential for inducing electrolyte abnormalities [e.g., furosemide (Lasix), hydrochlorothiazide] or antiarrhythmic drugs or other drugs that lead to QT prolongation [amiodarone (Nexterone), procainamide, quinidine]). ■ Serotonin syndrome has been reported with 5-HT_3 receptor antagonists. Most reports were associated with concomitant use of serotonergic drugs (e.g., selective serotonin reuptake inhibitors [e.g., paroxetine (Paxil), escitalopram (Lexapro)], serotonin and norepinephrine reuptake inhibitors [e.g., duloxetine (Cymbalta), venlafaxine (Effexor XR)], monoamine oxidase inhibitors [e.g., selegiline (Eldepryl)], mirtazapine [Remeron], fentanyl, lithium, tramadol [Ultram], and intravenous methylene blue). Some cases were fatal. ■ Cross-sensitivity has been reported in patients who received other selective 5HT_3-receptor agonists (e.g., granisetron [Kytril], ondansetron [Zofran]). These reactions have not been seen with dolasetron. ■ See Contraindications, Maternal/Child, Drug/Lab Interactions, and Side Effects.

Monitor:

Observe closely. Monitor VS. Any patient found to have a second-degree or higher AV conduction block should be monitored continuously. ■ Correct hypokalemia and hypomagnesemia before administration of dolasetron. Monitor after administration as clinically indicated. ■ Monitor ECG in patients with CHF, bradycardia, or renal impairment; in the elderly; and in all patients at risk for prolongation of the PR and QRS interval; see Precautions. ■ Monitor for serotonin syndrome, especially when dolasetron is used concurrently with other serotonergic drugs. Symptoms associated with serotonin syndrome may include the following combination of S/S: mental status changes (e.g., agitation, coma, delirium, hallucinations), autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile blood pressure, tachycardia), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), seizures, with or without GI symptoms (e.g., diarrhea, nausea, vomiting). ■ Ambulate slowly to avoid orthostatic hypotension.

Patient Education:

Request assistance for ambulation. ■ May cause serious cardiac arrhythmias; discuss medical history with physician and promptly report a perceived change in heart rate, fainting, or light-headedness. ■ Report promptly if nausea persists. ■ Maintain adequate hydration. ■ Review prescription medications with health care provider. ■ Promptly report S/S of serotonin syndrome (e.g., altered mental status, autonomic instability, and neuromuscular symptoms); see Precautions.

Maternal/Child:

Category B: no evidence of impaired fertility or harm to fetus. Use during pregnancy only if clearly needed. ■ Use caution if required during breast-feeding. ■ See Contraindications. ■ Safety and effectiveness for use in pediatric patients under 2 years of age not established. ■ Plasma clearance increased and half-life reduced in pediatric patients.

Elderly:

Use with caution and continuous ECG monitoring in the elderly; they are at particular risk for prolongation of the PR, QRS, and QT interval. ■ See Dose Adjustments and Contraindications.

DRUG/LAB INTERACTIONS

Does not induce or inhibit the cytochrome P_{450} drug metabolizing system, but metabolism of its active metabolite, hydrodolasetron, is mediated by enzymes in the P_{450} system. Plasma levels increased when given concurrently with **cimetidine** (Tagamet [inhibitor of cytochrome P_{450}]), and decreased when given concurrently with **rifampin** (Rifadin [inducer of cytochrome P_{450}]); clinical significance not known. ■ Clearance decreased when given concurrently with **atenolol.** ■ See Precautions and use extreme caution with **diuretics** with potential for inducing electrolyte abnormalities (e.g., furosemide [Lasix], hydrochlorothiazide) **or antiarrhythmic drugs or other drugs that lead to prolonged QT intervals** (e.g., amiodarone [Nexterone], procainamide, quinidine). ■ Serotonin syndrome (including altered mental status, autonomic instability, and neuromuscular symptoms) has been reported following the concomitant use of 5-HT_3 receptor antagonists and other serotonergic drugs, including selective serotonin reuptake inhibitors (SSRIs) and serotonin and norepinephrine reuptake inhibitors (SNRIs); see Precautions. ■ Clearance not affected by **ACE inhibitors** (e.g., enalapril), **diltiazem** (Cardizem), **furosemide** (Lasix), **glyburide** (DiaBeta), **nifedipine** (Procardia), **propranolol** (Inderal), and **verapamil**. ■ Does not influence anesthesia recovery time.

SIDE EFFECTS

Dizziness, drowsiness, headache, pain, and urinary retention are most common. Sinus arrhythmia, hypotension, orthostatic hypotension, and numerous other side effects may occur in fewer than 2% of patients. May cause bradycardia, severe hypotension, and syncope during or shortly after administration. Can cause ECG interval changes (PR, QT, JT prolongation, and QRS widening). These changes may lead to cardiovascular consequences (e.g., cardiac arrhythmias, heart block). Usually self-limiting with declining blood levels, but may last as long as 24 hours.

Overdose:

Severe hypotension and dizziness.

Post-Marketing:

Wide complex tachycardia, VT, VF, and cardiac arrest have been reported rarely. Serotonin syndrome has been reported as a 5-HT_3 class reaction.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed. Overdose in one patient was treated with plasma expanders (e.g., albumin, dextran), dopamine, atropine, and continuous BP and ECG monitoring. Epinephrine, atropine, and/or cardiac pacing may be required to treat ECG interval changes. Prolonged QT interval may lead to VT or other ventricular arrhythmias; telemetry monitoring may be indicated. If symptoms of serotonin syndrome occur, discontinue dolasetron and initiate supportive care. There is no specific antidote. Treat anaphylaxis and resuscitate as necessary. Not known if dolasetron is removed by hemodialysis.

DOPAMINE HYDROCHLORIDE BBW

(**DOH**-pah-meen hy-droh-**KLOR**-eyed)
Inotropic agent
Cardiac stimulant
Vasopressor
pH 2.5 to 5

USUAL DOSE

Where appropriate, restoration of blood volume with a suitable plasma expander or whole blood should be instituted or completed before administration of dopamine; the goal is a central venous pressure of 10 to 15 cm H_2O or a pulmonary wedge pressure of 14 to 18 mm Hg.

Adults:

2 to 5 mcg/kg of body weight/min initially in patients likely to respond to minimum treatment. 5 to 10 mcg/kg/min may be required initially to correct hypotension in the seriously ill patient. Gradually increase by 5 to 10 mcg/kg/min at 10- to 30-minute intervals until optimum response occurs. Average dose is 20 mcg/kg/min; over 50 mcg/kg/min has been required in some instances but is not recommended. If more than 20 mcg/kg/min is required to maintain BP, consider use of norepinephrine (Levophed) in addition. Doses over 20 mcg/kg/min decrease renal perfusion.

Bradycardia:

AHA guidelines recommend dopamine infusion 2 to 20 mcg/kg/min. Titrate to desired effect; taper slowly. Indicated if atropine is ineffective. Alternately, transcutaneous pacing or epinephrine infusion 2 to 10 mcg/min may be used.

PEDIATRIC DOSE

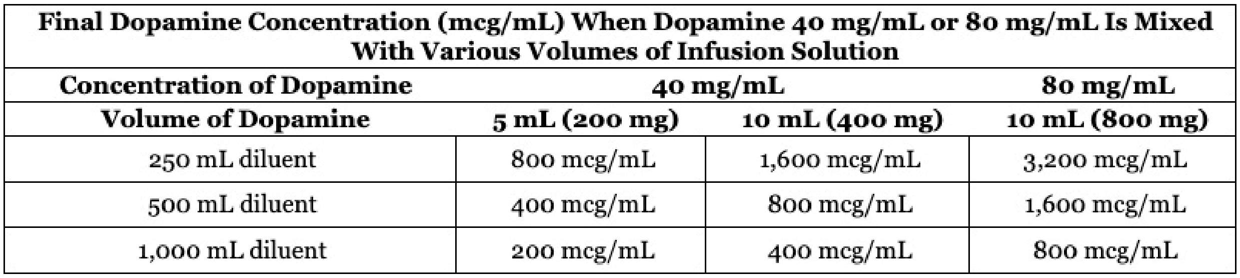
See Maternal/Child. Note comments in Usual Dose. Usual starting dose is 1 to 5 mcg/kg/min. Dose increments range from 2.5 to 5 mcg/kg/min. Usual maximum dose is 15 to 20 mcg/kg/min. Doses up to 50 mcg/kg/min have been administered. Titrate dose gradually to desired effect.

DOSE ADJUSTMENTS

Reduce dose to one-tenth of the calculated amount for individuals who have been treated with MAO inhibitors (e.g., selegiline) within 2 to 3 weeks of administration of dopamine. ■ Lower-end initial doses may be appropriate in the elderly based on potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce dose if possible if increased number of ectopic beats is observed. ■ See Drug/Lab Interactions.

DILUTION

Each 200-mg, 400-mg, or 800-mg ampule must be diluted in 250 to 500 mL of the following IV solutions and given as an infusion: NS, D5W, D5NS, D5/½NS, D5LR, ⅙ M sodium lactate, or LR injection. See the following chart.



Final Dopamine Concentration (mcg/mL) When Dopamine 40 mg/mL or 80 mg/mL Is Mixed With Various Volumes of Infusion Solution

Concentration of Dopamine	40 mg/mL		80 mg/mL
Volume of Dopamine	**5 mL (200 mg)**	**10 mL (400 mg)**	**10 mL (800 mg)**
250 mL diluent	800 mcg/mL	1,600 mcg/mL	3,200 mcg/mL
500 mL diluent	400 mcg/mL	800 mcg/mL	1,600 mcg/mL
1,000 mL diluent	200 mcg/mL	400 mcg/mL	800 mcg/mL

Also available prediluted in 250 mL or 500 mL of D5W. Dopamine concentration varies. More concentrated solutions may be used if absolutely necessary to reduce fluid volume.

Storage:

Store at CRT. Protect from freezing. Discard diluted solution after 24 hours. Do not use if solution is darker than slightly yellow.

COMPATIBILITY

Manufacturer states, "Do not add to sodium bicarbonate or any other strongly alkaline solution (e.g., aminophylline, barbiturates [e.g., phenobarbital]), oxidizing agents, or iron salts. Dopamine is inactivated in alkaline solution." Do not mix with alteplase or amphotericin B. Do not administer solutions containing dextrose through the same administration set as blood; may result in pseudoagglutination or hemolysis.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Begin with recommended dose for body weight and seriousness of condition. Gradually increase by 5 to 10 mcg/kg/min to produce desired response. Titrate to desired hemodynamic or renal response. When titrating to the desired increase in systolic BP, the optimum dosage rate for renal response may be exceeded and may necessitate a rate reduction after the hemodynamic condition is stabilized. Use of a volumetric infusion pump is recommended for accuracy. Optimum urine flow determines correct evaluation of dosage. Decrease dose gradually; may cause marked hypotension if discontinued suddenly. Expansion of blood volume with IV fluids may be indicated. If hypotension occurs at lower infusion rate, the infusion rate should be rapidly increased until adequate blood pressure is obtained. If hypotension continues, dopamine should be discontinued and a more potent vasoconstrictor agent (e.g., norepinephrine) should be administered. If a disproportionate rise in diastolic pressure is observed, the infusion rate should be decreased and the patient observed for further evidence of predominant vasoconstrictor activity unless such an effect is desired.

Dopamine Infusion Rate (mL/hr): 400 mcg/mL Concentration						
Desired Dose	**Weight in Kilograms**					
	50 kg (mL/hr)	**60 kg (mL/hr)**	**70 kg (mL/hr)**	**80 kg (mL/hr)**	**90 kg (mL/hr)**	**100 kg (mL/hr)**
5 mcg/kg/min	37.5	45	52.5	60	67.5	75
10 mcg/kg/min	75	90	105	120	135	150
20 mcg/kg/min	150	180	210	240	270	300
30 mcg/kg/min	225	270	315	360	405	450
40 mcg/kg/min	300	360	420	480	540	600

Dopamine Infusion Rate (mL/hr): 800 mcg/mL Concentration						
Desired Dose	**Weight in Kilograms**					
	50 kg (mL/hr)	**60 kg (mL/hr)**	**70 kg (mL/hr)**	**80 kg (mL/hr)**	**90 kg (mL/hr)**	**100 kg (mL/hr)**
5 mcg/kg/min	18.75	22.5	26.25	30	33.75	37.5
10 mcg/kg/min	37.5	45	52.5	60	67.5	75
20 mcg/kg/min	75	90	105	120	135	150
30 mcg/kg/min	112.5	135	157.5	180	202.5	225
40 mcg/kg/min	150	180	210	240	270	300

ACTIONS

Dopamine is a naturally occurring catecholamine that possesses alpha, beta, and dopaminergic receptor–stimulating actions. The effects of dopamine are dose-related. At low doses (0.5 to 2 mcg/kg/min), dopamine causes vasodilation in the renal, mesenteric, coronary, and intracerebral vascular beds, thereby increasing glomerular filtration rate, renal blood flow, sodium excretion, and urine flow. At medium doses (2 to 10 mcg/kg/min), beta-adrenoceptors are stimulated, resulting in improved myocardial contractility, increased sinoatrial rate, and enhanced impulse conduction in the heart. Systolic and pulse pressure may increase, but there is little, if any, effect on diastolic pressure at these doses. At higher doses (10 to 20 mcg/kg/min), alpha-adrenoceptors are stimulated, resulting in vasoconstriction and an increase in blood pressure. At doses above 20 mcg/kg/min, alpha effects predominate and vasoconstriction may compromise circulation in the limbs and override the dopaminergic effects of dopamine, reversing renal dilation and natriuresis. Dopamine is widely distributed. It has an onset of action of 5 minutes, a duration of action of 10 minutes, and a plasma half-life of 2 minutes. Metabolized in the liver, kidney, and plasma by monoamine oxidase (MAO) and catechol *O*-methyltransferase (COMT), with about 25% of the dose being converted to norepinephrine. Primarily excreted in urine.

INDICATIONS AND USES

To correct hemodynamic imbalances, including hypotension resulting from shock syndrome of myocardial infarction, trauma, endotoxic septicemia, open heart surgery, renal failure, and chronic cardiac decompensation. ■ Drug of choice for hypotension and shock. ■ AHA guidelines recommend dopamine as the second drug of choice after atropine to treat symptomatic bradycardia.

Unlabeled uses:

Chronic obstructive pulmonary disease, congestive heart failure, infant respiratory distress syndrome, symptomatic bradycardia, calcium channel blocker overdose, beta-blocker overdose, and drug-induced hypovolemic shock; consult literature.

CONTRAINDICATIONS

Hypersensitivity to any components (contains sulfites), pheochromocytoma, uncorrected tachyarrhythmias, ventricular fibrillation. Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Avoid bolus administration. ■ Some preparations contain sulfites; use caution in patients with allergies. ■ Use with caution in patients with known subclinical or overt diabetes mellitus. ■ IV administration of fluids may cause fluid overload, resulting in dilution of serum electrolyte concentrations, overhydration, a congested state, or pulmonary edema. ■ Avoid hypovolemia. ■ Presence of hypoxia, hypercapnia, or acidosis may reduce the effectiveness of dopamine and/or increase the incidence of dopamine-induced adverse events. ■ Ventricular arrhythmias have been reported. Reduce dose if possible if an increased number of ectopic beats is observed. ■ Use caution in patients with a history of occlusive vascular disease (e.g., atherosclerosis, arterial embolism, Raynaud's disease, cold injury, diabetic endarteritis, and Buerger's disease). ■ Excess administration of potassium-free solutions may result in significant hypokalemia. ■ See Dose Adjustments and Drug/Lab Interactions.

Monitor:

Recognition of signs and symptoms of hemodynamic imbalance and prompt treatment with dopamine will improve prognosis. ■ Close monitoring of BP, cardiac output, cardiac rhythm, and urine output required. Avoid hypertension. If possible, check central venous pressure or pulmonary wedge pressure before administration and as ordered thereafter. ■ Use larger veins (antecubital fossa) and avoid extravasation; may cause necrosis and sloughing of tissue. Central vein preferred for continuous infusions; see Antidote. ■ If possible, correct hypovolemia with IV fluids, whole blood or plasma as indicated; correct acidosis if present. ■ Monitor for decreased urine output, increased tachycardia, or new arrhythmias. ■ With high-dose administration, palpate pulses and monitor extremities for signs of peripheral vasoconstriction (e.g., coldness, paresthesias). ■ Therapy may be continued until the patient can maintain hemodynamic and renal functions. ■ Monitor changes in fluid balance, electrolyte concentration, and acid-base balance during prolonged parenteral therapy or whenever patient's condition warrants such evaluation. ■ See Maternal/Child and Drug/Lab Interactions.

Maternal/Child:

Safety for use in pregnancy and breast-feeding not established. If used, benefits must outweigh risks. ■ Safety for use in pediatric patients not established. Has been used, but experience is limited. ■ Do not administer into an umbilical arterial catheter. Vasospastic events have been reported when dopamine is infused through the umbilical artery.

Elderly:

Lower-end initial doses may be appropriate; see Dose Adjustments. ■ Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Alkaline solutions, including sodium bicarbonate, inactivate dopamine. ■ May cause serious arrhythmias in presence of **cyclopropane or halogen anesthetics.** ■ May cause severe hypertension with **oxytocic drugs** (e.g., methylergonovine or oxytocin). ■ **MAO inhibitors** prolong and potentiate the effect of dopamine. Concurrent use may cause hypertensive crisis. ■ Concurrent administration of low-dose dopamine and diuretic agents may produce an additive or potentiating effect on urine flow. ■ Antagonizes effects of **guanethidine**. ■ Cardiac effects may be antagonized by **alpha- or beta-blocking agents**. ■ **Tricyclic antidepressants** may potentiate the cardiovascular effects of dopamine. ■ May cause severe bradycardia and hypotension with **phenytoin**. ■ **Alpha-adrenergic blocking agents**

antagonize the peripheral vasoconstriction caused by high-dose dopamine. ■ **Butyrophenones** (e.g., haloperidol) and **phenothiazines** (e.g., chlorpromazine, prochlorperazine) can suppress the dopaminergic renal and mesenteric vasodilation induced with low-dose dopamine. ■ See Dose Adjustments.

SIDE EFFECTS

Aberrant conduction/arrhythmias (e.g., atrial fibrillation, ectopic beats, widened QRS complex, ventricular arrhythmias), anginal pain, anxiety, azotemia, bradycardia, dyspnea, headache, hypertension, hypotension, nausea, palpitation, piloerection, tachycardia, vasoconstriction, vomiting. Gangrene of the extremities has occurred with high doses administered for prolonged periods and in patients with occlusive vascular disease receiving a low dose of dopamine.

ANTIDOTE

Notify the physician of all side effects. Decrease infusion rate and notify the physician immediately for decrease in established urine flow rate, disproportionate rise in diastolic BP (i.e., a marked decrease in pulse pressure), increasing tachycardia, or new arrhythmias. For accidental overdosage with hypertension, reduce rate or temporarily discontinue until condition stabilizes. Phentolamine, an alpha-adrenergic blocker, may be useful in an overdose situation that does not respond to discontinuation of dopamine. To prevent sloughing and necrosis in areas where extravasation has occurred, use a fine hypodermic needle to inject 5 to 10 mg of phentolamine (Regitine) diluted in 10 to 15 mL normal saline liberally throughout the tissue in the extravasated area. Begin as soon as extravasation is recognized.

DOXAPRAM HYDROCHLORIDE

(**DOX**-ah-pram hy-droh-**KLOR**-eyed)
Dopram
Respiratory stimulant
Analeptic
pH 3.5 to 5

USUAL DOSE

Pretreatment:

Specific testing may be indicated before administration; see Precautions.

In all situations, do not exceed 3 Gm/24 hr. Minimum effective dosage is recommended. Repetitive doses are to be used only if the initial dose elicits a positive response.

Postanesthesia respiratory depression: *Injection:*

An initial dose of 0.5 to 1 mg/kg. May be repeated every 5 minutes. Maximum single dose is 1.5 mg/kg. Maximum total dose is 2 mg/kg. ***Infusion:*** 0.5 to 1 mg/kg as a continuous infusion at a rate of 5 mg/min until response. Maintain with 1 to 3 mg/min.

4 mg/kg or a total dose of 300 mg for the average adult is the recommended total dose by infusion.

Drug-induced CNS depression (mild):

An initial dose of 1 mg/kg. May repeat in 5 minutes and every 1 to 2 hours until sustained arousal. Alternately, an initial dose of 1 mg/kg may be followed by a continuous infusion of 1 to 2 mg/kg/hr. Discontinue if patient awakens or at the end of 2 hours. After patient awakens, monitor for relapse into unconsciousness or the development of respiratory depression (does not affect the metabolism of CNS-depressant drugs). If a relapse occurs, resume injections every 1 to 2 hours until arousal is sustained or a total maximum daily dose (3 Gm) is given. Allow patient to sleep until 24 hours after the first injection; use assisted or automatic respiration if necessary. After this 24-hour lapse, repeat procedure until patient breathes spontaneously and sustains the desired level of consciousness or until the maximum dose (3 Gm) has been given.

Drug-induced CNS depression (moderate):

An initial dose of 2 mg/kg. May repeat in 5 minutes and every 1 to 2 hours until sustained arousal. Alternately, an initial dose of 2 mg/kg may be followed by a continuous infusion of 2 to 3 mg/kg/hr. Discontinue if patient awakens or at the end of 2 hours. See comments under Drug-induced CNS depression (mild).

Chronic obstructive pulmonary disease:

1 to 2 mg/min. Maximum dose is 3 mg/min over no more than 2 hours. Maximum total dose is 360 mg. Repeat doses not recommended.

Shivering:

A single dose of 0.18 mg/kg as an injection.

NEONATAL DOSE

Safety and effectiveness in pediatric patients under 12 years of age not established; see Maternal/Child.

Methylxanthine-refractory neonatal apnea (unlabeled):

0.5 to 2.5 mg/kg/hr as an IV infusion. Another source suggests a ***loading dose*** of 2.5 to 3 mg/kg as an infusion over 15 minutes. Follow with a continuous infusion of 1 mg/kg/hr titrated to the lowest effective dose. Maximum recommended dose is 2.5 mg/kg/hr. 0.5 to 2.5 mg/kg/hr will result in benzyl alcohol doses from 5.4 to 27 mg/kg daily; use not recommended.

DILUTION

May be given undiluted or diluted with equal parts of SW for injection; or dilute 250 mg (12.5 mL) in 250 mL D5W, D10W, D5NS, D10NS, or NS and give as an infusion.

Chronic obstructive pulmonary disease:

Dilute 400 mg in 180 mL infusion fluid (2 mg/mL). May be given by slow IV injection or infusion.

Storage:

Store at CRT.

COMPATIBILITY

Manufacturer states, “Admixture with alkaline solutions such as aminophylline, furosemide (Lasix), sodium bicarbonate, or thiopental (Pentothal) will result in precipitation or gas formation.” Manufacturer also lists as incompatible with ascorbic acid, cefotaxime (Claforan), cefotetan, cefuroxime (Zinacef), dexamethasone, diazepam (Valium), folic acid, hydrocortisone sodium succinate (Solu-Cortef), methylprednisolone Solu-Medrol).

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Rapid infusion may result in hemolysis.

Post-anesthesia respiratory depression:

Total desired dose of undiluted medication over 5 minutes. Infusion rate may start at 5 mg/min; decrease to 1 to 3 mg/min with observance of respiratory response. If an infusion is used after the initial priming dose, rate may start at 1 to 3 mg/min depending on patient response. Discontinue use after 2 hours, wait 1 to 2 hours, and repeat entire process. Use an infusion pump or microdrip (60 gtt/mL) for accuracy. See Monitor.

Chronic obstructive pulmonary disease:

Specific dose over a 2-hour period. Begin at 1 to 2 mg/min. May be titrated to response by injection or infusion. ***Never*** exceed 3 mg/min.

ACTIONS

An analeptic CNS stimulant. Affects medullary respiratory center to increase the depth of respiration and to slightly increase the rate. Achieves maximum effect in 2 minutes and lasts about 5 to 12 minutes with a single dose. Elevates BP and HR. Rapidly metabolized. See Precautions.

INDICATIONS AND USES

Post-anesthesia:

To pharmacologically stimulate deep breathing in the postoperative patient. ■ After eliminating the possibility of airway obstruction and/or hypoxia, may be used to stimulate respiration in patients with drug-induced post-anesthesia respiratory depression or apnea other than that due to **muscle-relaxant** drugs.

Drug-induced CNS depression:

To stimulate respiration, hasten arousal, and encourage the return of laryngopharyngeal reflexes in patients with mild to moderate respiratory and CNS depression due to drug overdose; see Precautions.

Chronic pulmonary disease associated with acute hypercapnia:

As a temporary measure in hospitalized patients with acute respiratory insufficiency superimposed on chronic obstructive pulmonary disease (COPD). Its use should be for a short period of time as an aid in the prevention of elevation of arterial CO_2 tension during administration of O_2. Do not use in conjunction with mechanical ventilation.

Unlabeled uses:

Has been used for the treatment of neonatal apnea when methylxanthines (e.g., caffeine, theophyllines) have failed.

CONTRAINDICATIONS

Cardiovascular impairment (significant), cerebral edema, cerebrovascular accidents, convulsive states of any etiology, coronary artery disease, head injury, heart failure (uncompensated), hypertension (severe), inadequate ventilation capacity, known hypersensitivity to doxapram or any of its components, neonates, proven or suspected pulmonary embolism. ■ Patients with mechanical disorders of ventilation, such as acute bronchial asthma, flail chest, mechanical obstruction, muscle paresis (including neuromuscular blockade), pneumothorax, pulmonary fibrosis, or other conditions resulting in restriction of chest wall, muscles of respiration, or alveolar expansion.

PRECAUTIONS

Do not use in conjunction with mechanical ventilation. ■ Rule out airway obstruction, hypoxia, and/or apnea due to muscle relaxants before use. ■ Not an antagonist to muscle relaxant drugs or a specific narcotic antagonist. Specific tests (e.g., peripheral nerve stimulation, pulse oximetry, end tidal carbon dioxide) to assess adequacy of ventilation are recommended before administration. ■ Anticonvulsants such as IV short-acting barbiturates (e.g., pentobarbital [Nembutal]), oxygen, and resuscitative equipment must be available. ■ Adjunctive therapy only. May not stimulate adequate spontaneous breathing or provide sufficient arousal in patients who are ***severely*** depressed due to either respiratory or CNS-depressant drugs. ■ Stimulates systemic epinephrine increase. ■ Use care in agitation, cardiac arrhythmias or disease, gastric surgery, hyperthyroidism, increased intracranial pressure, pheochromocytoma, tachycardia, ulcers, and hepatic or renal impairment.

Monitor:

Maintain an adequate airway at all times. May induce vomiting; protect airway. Oxygen and facilities for controlled ventilation must be available. ■ Observe patient continuously and monitor BP, pulse, and deep tendon reflexes during therapy until 1 hour after doxapram is discontinued. Adjust rate if indicated. ■ Mild depression is classified as either Class 0 (asleep but can be aroused and answer questions) or Class 1 (comatose, will withdraw from painful stimuli, reflexes intact). Moderate depression is classified as Class 2 (comatose, will not withdraw from painful stimuli, reflexes intact) or Class 3 (comatose, reflexes absent, no depression of circulation or respiration). ■ Arterial blood gas measurements are desirable to determine effective ventilation. ■ Failure to respond to treatment may indicate CNS source for sustained coma; requires neurologic evaluation; repeat doses are not indicated. ■ Confirm patency of vein; vascular extravasation and thrombophlebitis can result from extended use.

Chronic obstructive pulmonary disease:

Arterial blood gases (ABGs) before administration and every 30 minutes thereafter are mandatory ***to ensure against the insidious development of CO_2* retention and acidosis.** Do not use in conjunction with mechanical ventilation. Adjust rate of infusion and oxygen delivery as indicated by arterial blood gases and patient response. Consider increased work of breathing. Observe for CO_2 retention and acidosis. If ABGs deteriorate, discontinue doxapram and initiate mechanical ventilation. Repeat infusions not recommended. ■ See Drug/Lab Interactions.

Maternal/Child:

Category B: safety for use in pregnancy, breast-feeding, and pediatric patients under 12 years of age not established. ■ Administration to premature neonates has resulted in serious side effects (e.g., abdominal distention, bloody stools, disturbed sleep, erratic limb movements, excessive crying, glucosuria, hyperglycemia, hypertension, increased gastric residuals, irritability, jitteriness, necrotizing enterocolitis, premature eruption of teeth, QT prolongation resulting in heart block and vomiting). Seizures have occurred in premature neonates with risk factors (e.g., intracerebral hemorrhage, perinatal asphyxia, previous seizure); occurred in many instances when doxapram was administered after xanthines (e.g., caffeine, aminophylline, theophylline). ■ Contains benzyl alcohol; a preservative-free preparation is not available in the United States. ■ Contains benzyl alcohol; has been associated with a fatal “gasping syndrome” in neonates. ■ See Contraindications.

DRUG/LAB INTERACTIONS

Sympathomimetics (e.g., epinephrine), **MAO inhibitors** (e.g., selegiline [Eldepryl]), **and vasopressors** (e.g., dobutamine, isoproterenol) may increase pressor effects when used concurrently with doxapram and produce excessive hypertension. ■ In patients who have received a **volatile anesthetic agent** (e.g., cyclopropane, halothane) known to sensitize the myocardium to catecholamines, delay administration of doxapram until the volatile agent has been excreted to reduce the potential for cardiac arrhythmias. ■ May temporarily mask the residual effects of **muscle relaxants** (e.g., cisatracurium [Nimbex], diazepam [Valium]). ■ Increased skeletal muscle activity, agitation, and hyperactivity may result from concurrent use with **aminophylline or theophylline.**

SIDE EFFECTS

Albuminuria; apprehension; chest pain or tightness; clonus; confusion; cough; decreased hemoglobin, hematocrit, and RBCs; diaphoresis; diarrhea; disorientation; dizziness; dyspnea; elevated BUN; fever; flushing; hallucinations; headache; hemolysis;

hiccups; hyperactivity; hyperventilation; involuntary movements; muscle fasciculations; muscle spasticity; nausea; paresthesias; phlebitis; pruritus; pupillary dilation; pyrexia; salivation; tachypnea; urinary retention or urgency; vomiting; warmth.

Major:

Aggravated deep tendon reflexes, arrhythmias (e.g., VT, VF), bilateral Babinski sign, bronchospasm, convulsions, hypertension, hypotension, laryngospasm, PVCs, respiratory alkalosis, skeletal muscle spasm, tachycardia.

Chronic obstructive pulmonary disease:

Acidosis and CO_2 retention.

ANTIDOTE

Notify physician of any side effect. Depending on severity, physician may elect to continue the drug at a reduced rate of administration or discontinue it. Discontinue doxapram with onset of sudden hypotension or dyspnea. Oxygen and IV diazepam (Valium) or pentobarbital sodium (Nembutal) may be useful in overdose. Discontinue doxapram if blood gases deteriorate. Resuscitate as necessary.

DOXERCALCIFEROL

(**DOX**-err-kal-**sif**-er-ol)
Hectorol Injection
Vitamin D analog

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Optimal dose of doxercalciferol must be individualized. The dose is adjusted in an attempt to achieve intact parathyroid hormone (iPTH) levels within a targeted range of 150 to 300 pg/mL. See Precautions and Monitor. Recommended initial dose for a patient with an iPTH level greater than 400 pg/mL is 4 mcg administered as a bolus dose three times weekly at the end of dialysis (approximately every other day). Total weekly dose is 12 mcg/week. Maximum dose was limited to 18 mcg/week in clinical studies.

DOSE ADJUSTMENTS

Adjust dosing based on patient response in order to lower blood iPTH into the range of 150 to 300 pg/mL. The dose may be increased at 8-week intervals by 1 to 2 mcg if iPTH is not lowered by 50% and fails to reach the target range. Doses higher than 18 mcg weekly have not been studied. During titration monitor iPTH, serum calcium, phosphorus, and calcium × phosphorus product (Ca × P) weekly. Maximize iPTH suppression while maintaining serum calcium and phosphorous levels in prescribed ranges; see Monitor. ■ Immediately suspend dosing if hypercalcemia, hyperphosphatemia, or a Ca × P product of greater than 55 mg^2/dL^2 is noted. Reinitiate therapy at a dose that is 1 mcg lower when parameters have normalized. ■ Patients with impaired hepatic function may not metabolize doxercalciferol appropriately; see Precautions. ■ The following chart is a suggested approach to dose titration.

Suggested Dose Adjustment Guidelines for Doxercalciferol	
iPTH Level	**Doxercalciferol Dose Guidelines**
Decreased by <50% and above 300 pg/mL	Increase by 1 to 2 mcg at 8-week intervals as necessary
Decreased by >50% and above 300 pg/mL	Maintain
150 to 300 pg/mL	Maintain
<100 pg/mL	Suspend for 1 week, then resume at a dose that is at least 1 mcg lower

DILUTION

May be given undiluted. Available as a single-use injection containing either 4 mcg/2 mL or 2 mcg/mL and as a multidose injection containing 4 mcg/2 mL.

Storage:

Store unopened vials at 25° C (77° F); range: 15° to 30° C (59° to 86° F). Protect from light. Discard unused portion of single-use vial. After initial multidose vial use, the contents remain stable up to 3 days when stored at 2° to 8° C (36° to 46° F). Discard unused portion of multidose vial after 3 days.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as a bolus dose at the end of dialysis.

ACTIONS

A synthetic vitamin D analog. Metabolizes to a naturally occurring, biologically active form of vitamin D_2 that regulates blood calcium at levels required for essential body functions (i.e., intestinal absorption of dietary calcium, tubular reabsorption of calcium by the kidney and, in conjunction with the parathyroid hormone [PTH], the mobilization of calcium from the skeleton). Acts directly on bone cells (osteoblasts) to stimulate skeletal growth and on the parathyroid glands to suppress PTH synthesis and secretion. In uremic patients, deficient production of biologically active vitamin D metabolites leads to secondary hyperparathyroidism, which contributes to the development of metabolic bone disease. Doxercalciferol is activated in the liver. Peak blood levels are reached in 2.1 to 13.9 hours. Mean half-life range is 32 to 96 hours.

INDICATIONS AND USES

Treatment of secondary hyperparathyroidism in patients with chronic kidney disease undergoing dialysis.

CONTRAINDICATIONS

Evidence of vitamin D toxicity, hypercalcemia, hyperphosphatemia, or known hypersensitivity to any ingredient in this product; see Precautions.

PRECAUTIONS

Overdose of any form of vitamin D, including doxercalciferol, is dangerous. Progressive hypercalcemia due to overdose of vitamin D and its metabolites may require emergency attention. Acute hypercalcemia may exacerbate tendencies for cardiac arrhythmias and seizures and may potentiate the action of digoxin drugs. Chronic hypercalcemia can lead to elevated Ca × P product, and generalized vascular and other soft-tissue calcification. If clinically significant hypercalcemia develops, dose should be reduced or held. Do not allow the Ca × P product to exceed 55 mg^2/dL^2. See Side Effects and Antidote. ■ To avoid possible additive effects and hypercalcemia, vitamin D–related compounds should not be taken concomitantly with doxercalciferol. ■ Serious hypersensitivity reactions, including fatal outcome, have been reported. ■ Oversuppression of iPTH levels may lead to a dynamic bone syndrome. ■ Hyperphosphatemia can exacerbate hyperparathyroidism. ■ Use caution in patients with impaired hepatic function. More frequent monitoring of iPTH, calcium, and phosphorus levels is recommended. ■ Patients with higher pretreatment serum levels of calcium (more than 10.5 mg/dL) or phosphorus (more than 6.9 mg/dL) may be more likely to experience hypercalcemia or hyperphosphatemia; see Contraindications.

Monitor:

During initiation of therapy, obtain baseline serum iPTH, calcium, and phosphorus levels, and determine levels weekly during the early phase of treatment (i.e., first 12 weeks). For dialysis patients, serum or plasma iPTH and serum calcium, phosphorus, and alkaline phosphatase should be determined periodically. See Dose Adjustments. ■ Calculate Ca × P (should be less than 55 mg^2/dL^2). ■ Monitor serum calcium levels weekly after all dose changes and during subsequent dose titration. ■ Monitor for signs and symptoms of hypercalcemia. See Side Effects. Radiographic evaluation of suspect anatomical regions may be useful in the early detection of generalized vascular or other soft-tissue calcification. ■ Oral calcium-based or other non–aluminum-containing phosphate binders and a low phosphate diet are indicated to control serum phosphorus levels in dialysis patients. Hyperphosphatemia can lessen the effectiveness of doxercalciferol in reducing blood PTH levels. After initiating doxercalciferol therapy, the dose of calcium-containing phosphate binders should be decreased to correct persistent mild hypercalcemia (10.6 to 11.2 mg/dL for 3 consecutive determinations), or increased to correct persistent mild hyperphosphatemia (7 to 8 mg/dL for 3 consecutive determinations). ■ Persistent or markedly elevated serum calcium levels may be corrected by dialysis against a reduced calcium or calcium-free dialysate. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis with symptoms of angioedema [involving face, lips, tongue, and airways], cardiopulmonary arrest, chest discomfort, hypotension, shortness of breath, unresponsiveness). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Report symptoms of hypercalcemia promptly. Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and restriction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate, sevelamer) may be needed to control serum phosphorus levels in patients with CRF, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel) should be avoided. ■ Review all nonprescription drugs with physician.

Maternal/Child:

Category B: safety for use in pregnancy not established; use only if clearly needed. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in effectiveness or safety observed.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ **Digoxin** toxicity is potentiated by hypercalcemia. Use caution when doxercalciferol is prescribed concomitantly with digoxin compounds. ■ **Phosphate or vitamin D**–related compounds should not be taken concomitantly with doxercalciferol. ■ May reduce serum total **alkaline phosphatase levels.** ■ **Magnesium-containing antacids** may cause hypermagnesemia; concomitant use is not recommended. ■ Concomitant use with **cytochrome P_{450} enzyme inducers** (e.g., phenobarbital, phenytoin, rifampin) may affect hydroxylation of doxercalciferol and require dose adjustments. ■ Concomitant use with **cytochrome P_{450} enzyme inhibitors** (e.g., erythromycin, ketoconazole) may inhibit metabolism of the active form of vitamin D, decreasing effectiveness.

SIDE EFFECTS

Dose-limiting side effects are hypercalcemia, hyperphosphatemia, and oversuppression of iPTH (less than 150 pg/mL). Overdose or chronic administration may lead to hypercalcemia. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include: ***Early:*** anorexia, bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. ***Late:*** albuminuria, anorexia, apathy, arrested growth, cardiac arrhythmias, conjunctivitis (calcific), death, decreased libido, dehydration, ectopic calcification, elevated AST and ALT, elevated BUN, hypercholesterolemia, hypertension, hyperthermia, nocturia, overt psychosis (rare), pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, sensory disturbances, urinary tract infections, and weight loss.

Post-Marketing:

Hypersensitivity reactions, including fatal outcome (e.g., anaphylaxis with symptoms of angioedema [involving face, lips, tongue, and airways], cardiopulmonary arrest, chest discomfort, hypotension, shortness of breath, unresponsiveness).

Overdose:

Hypercalcemia, hypercalciuria, hyperphosphatemia, and oversuppression of PTH secretion leading in certain cases to adynamic bone disease. High intake of calcium and phosphate concomitant with doxercalciferol may lead to similar abnormalities. High levels of calcium in the dialysate bath may contribute to hypercalcemia.

ANTIDOTE

Notify physician of any side effects. Treatment of patients with clinically significant hypercalcemia (more than 1 mg/dL above the upper limit of normal range) consists of immediate dose reduction or interruption of the therapy and includes a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), forced diuresis, and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Monitor serum calcium levels frequently until calcium levels return to within normal limits. Not removed from blood during hemodialysis. When serum calcium levels return to within normal limits (usually 2 to 7 days), therapy may be restarted at a dose that is at least 1 mcg lower than prior therapy. Should a hypersensitivity reaction occur, discontinue doxercalciferol and initiate appropriate treatment and monitoring as indicated.

DOXORUBICIN HYDROCHLORIDE BBW ■ DOXORUBICIN HYDROCHLORIDE LIPOSOMAL INJECTION BBW

pH 3.8 to 6.5 ■ pH 6.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Assessment required before dosing; see Precautions and Monitor.

Conventional Doxorubicin

60 to 75 mg/M^2 once every 21 days as a ***single agent.*** When used in ***combination*** with other agents, the most common dose of doxorubicin is 40 to 75 mg/M^2 every 21 to

28 days.

Breast cancer with lymph node involvement after resection:

Doxorubicin 60 mg/M² in combination with cyclophosphamide 600 mg/M² given IV sequentially on Day 1 of each 21-day treatment cycle. Four cycles have been administered.

Adjuvant treatment of operable node-positive breast cancer:

Treatment protocol includes doxorubicin, cyclophosphamide, and docetaxel. Administer doxorubicin 50 mg/M² and cyclophosphamide 500 mg/M². One hour later, give docetaxel 75 mg/M². Repeat every 3 weeks for 6 cycles. See docetaxel and cyclophosphamide monographs.

Doxil (Liposomal Doxorubicin)

Do not substitute Doxil for conventional doxorubicin.

AIDS-related Kaposi's sarcoma:

20 mg/M² as an IV infusion over 60 minutes every 21 days until disease progression or unacceptable toxicity.

Ovarian cancer:

50 mg/M² as an IV infusion over 60 minutes every 28 days until disease progression or unacceptable toxicity.

Multiple myeloma:

Given in combination with bortezomib (Velcade).

Bortezomib:

Administer 1.3 mg/M² as an IV bolus on Days 1, 4, 8, and 11 of each 21-day cycle; see bortezomib monograph.

Doxil:

Administer 30 mg/M² as an IV infusion over 60 minutes on Day 4 of each 21-day cycle following bortezomib. Continue regimen for 8 cycles or until disease progression or the occurrence of unacceptable toxicity.

Breast cancer (unlabeled):

50 mg/M² as an IV infusion over 60 minutes every 4 weeks. Other combination protocols are in use.

PEDIATRIC DOSE

Conventional Doxorubicin:

In combination with other chemotherapeutic agents as first-line treatment, 30 to 60 mg/M^2 every 21 to 42 days. See Maternal/Child.

Doxil:

Safety for use in pediatric patients not established.

DOSE ADJUSTMENTS

Conventional Doxorubicins:

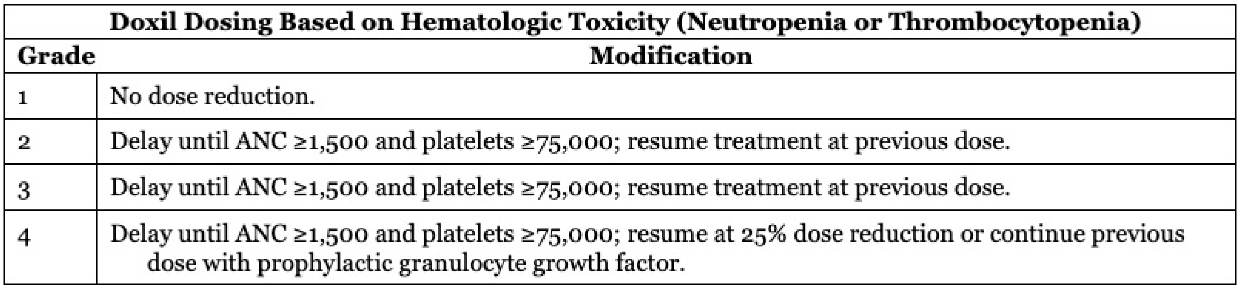
Reduce dose in patients with impaired hepatic function. ***Elevated serum bilirubin:*** Give 50% of above doses for serum bilirubin from 1.2 to 3 mg/mL and 25% of above doses for serum bilirubin above 3 mg/mL. Discontinue therapy for serum bilirubin greater than 5 mg/dL. ■ See Precautions. ■ Consider lower-end doses or longer intervals between cycles for heavily pretreated patients, elderly patients, or obese patients.

Breast cancer with lymph node involvement after resection:

Reduce dose to 75% of the starting dose for neutropenic fever/infection. If necessary, delay the next cycle of treatment until the ANC is 1,000 cells/mm^3 or more and the platelet count is 100,000 cells/mm^3 or more and nonhematologic toxicities have resolved.

Doxil:

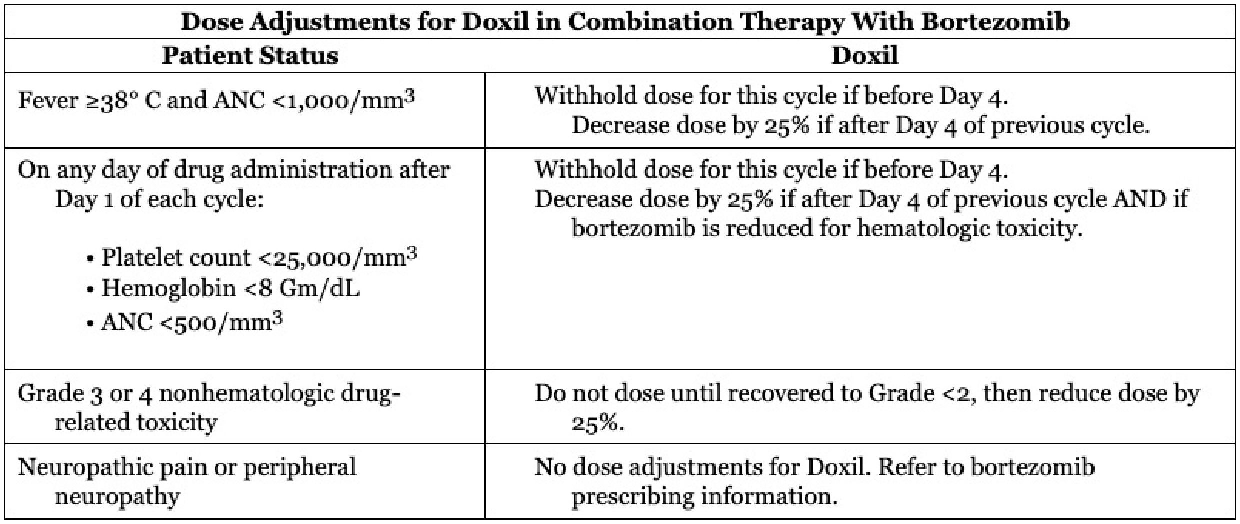
Reduce dose for serum bilirubin of 1.2 or higher. ■ Dose adjustments are required in hematologic toxicity (see the following chart) and in patients with stomatitis or hand-foot syndrome (HFS) (see product literature for guidelines). Adjust or delay a dose as described in the product literature at the first sign of a Grade 1 or higher adverse event. ■ Do not increase Doxil dose after a dose reduction for toxicity.



Doxil Dosing Based on Hematologic Toxicity (Neutropenia or Thrombocytopenia)

Grade	Modification
1	No dose reduction.
2	Delay until ANC ≥1,500 and platelets ≥75,000; resume treatment at previous dose.
3	Delay until ANC ≥1,500 and platelets ≥75,000; resume treatment at previous dose.
4	Delay until ANC ≥1,500 and platelets ≥75,000; resume at 25% dose reduction or continue previous dose with prophylactic granulocyte growth factor.

Dose adjustments for Doxil in combination therapy with bortezomib for treatment of multiple myeloma are listed in the following chart. See bortezomib monograph for bortezomib dose adjustments.



Dose Adjustments for Doxil in Combination Therapy With Bortezomib

Patient Status	Doxil
Fever ≥38° C and ANC <1,000/mm³	Withhold dose for this cycle if before Day 4. Decrease dose by 25% if after Day 4 of previous cycle.
On any day of drug administration after Day 1 of each cycle: • Platelet count <25,000/mm³ • Hemoglobin <8 Gm/dL • ANC <500/mm³	Withhold dose for this cycle if before Day 4. Decrease dose by 25% if after Day 4 of previous cycle AND if bortezomib is reduced for hematologic toxicity.
Grade 3 or 4 nonhematologic drug-related toxicity	Do not dose until recovered to Grade <2, then reduce dose by 25%.
Neuropathic pain or peripheral neuropathy	No dose adjustments for Doxil. Refer to bortezomib prescribing information.

DILUTION

Specific techniques required;

see Precautions**.**

Conventional Doxorubicin:

Each 10 mg must be diluted with 5 mL of NS to obtain a final concentration of 2 mg/mL. Do not use bacteriostatic diluent. Shake gently to dissolve completely. Also available in preservative-free solutions. May be further diluted in 50 mL or more D5W or NS and given as a continuous infusion through a central venous line.

Doxil:

Doses up to 90 mg must be diluted in 250 mL D5W. Not a clear solution, but a translucent red liposomal dispersion. Do not use filters. Doses over 90 mg should be diluted in 500 mL D5W. See Compatibility.

Filters:

Conventional doxorubicin:

Data not available from manufacturer; however, one source indicates no evidence of drug loss when administered through a 0.2-micron in-line nylon filter, and another source indicates no significant drug loss using various types of 0.2-micron filters.

Doxil:

Do not use filters during preparation or administration.

Storage:

Conventional doxorubicin:

Retain vials in carton until time of use. Refrigerate unopened vials containing solution.

Refrigeration can result in the formation of a gelled product. If this occurs, place vial at RT for 2 to 4 hours to return the product to a slightly viscous mobile solution. Vials containing lyophilized powder may be stored at CRT. All forms should be protected from light.

Doxil:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Refrigerate diluted solution and use within 24 hours.

COMPATIBILITY

Conventional Doxorubicin

Manufacturer lists fluorouracil and heparin as **incompatible** and states mixing with other drugs is not recommended unless specific **compatibility** data available. Avoid contact with alkaline solutions; can lead to hydrolysis of doxorubicin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Doxil

Manufacturer states, "Do not mix Doxil with other drugs. Do not use any other diluent (use D5W only). Do not use any bacteriostatic agents (e.g., benzyl alcohol)."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Conventional Doxorubicin

IV injection:

A single dose of properly diluted medication over a minimum of 3 to 10 minutes. Should be given through a central line or a secure and free-flowing peripheral venous line containing NS, ½NS, or D5W. Slow injection rate further for erythematous streaking along the vein or facial flushing.

Continuous infusion:

Central venous line required. Equally distributed over time interval outlined in given protocol.

Doxil

Do not administer as an undiluted suspension or as an IV bolus. For IV infusion only. Rapid infusion may increase risk of acute infusion-related reactions. Primarily occurs during the first infusion; may resolve with a reduced rate or may take up to a day after infusion completed to resolve.

Begin with an initial rate of 1 mg/min to minimize the risk of infusion reactions. If no adverse infusion-related effects, the rate may be increased from the initial rate of 1 mg/min to evenly distribute and complete infusion over 1 hour. Avoid rapid flushing of the infusion line.

ACTIONS

Conventional Doxorubicin:

A highly cytotoxic anthracycline topoisomerase II inhibitor that is cell-cycle specific for the S phase. Widely distributed and rapidly cleared from plasma, it interferes with cell division by binding with DNA to slow production of nucleic acid synthesis. Metabolized in the liver. Elimination half-life is 20 to 48 hours. Does not cross blood-brain barrier. Slowly excreted in bile and urine. Secreted in breast milk.

Doxil:

Doxorubicin encapsulated in long-circulating STEALTH liposomes (phospholipids). The small size of these liposomes and their persistence in the circulation enable them to evade immune system detection and penetrate the often altered and/or compromised vasculature of tumors. Once distributed to tumor tissue, the doxorubicin is released by an unknown mechanism. It differs from conventional doxorubicin because it mostly confines itself to vascular fluid volume. Metabolized and eliminated renally. Plasma clearance is slower. Half-life is extended to 55 hours. Concentration in Kaposi's sarcoma lesions is much higher than in normal skin (range is 3 to 53 times higher).

INDICATIONS AND USES

Conventional Doxorubicin:

Adjuvant therapy in women with evidence of axillary lymph node involvement following resection of primary breast cancer. ■ Treatment of acute lymphoblastic leukemia, acute myeloblastic leukemia, Hodgkin lymphoma, non-Hodgkin lymphoma, metastatic breast cancer, metastatic Wilms' tumor, metastatic neuroblastoma, metastatic soft tissue sarcoma, metastatic bone sarcoma, metastatic ovarian carcinoma, metastatic transitional cell bladder carcinoma, metastatic thyroid carcinoma, metastatic gastric carcinoma, metastatic bronchogenic carcinoma.

Doxil:

Treatment of AIDS-related Kaposi's sarcoma in patients after failure of prior systemic chemotherapy or in patients who are intolerant to such therapy. ■ Treatment of patients with ovarian cancer whose disease has progressed or recurred after platinum-based chemotherapy (e.g., cisplatin, carboplatin). ■ Treatment of multiple myeloma in combination with bortezomib (Velcade) in patients who have received one prior therapy but have not previously received bortezomib.

Unlabeled uses:

Doxil:

Treatment of refractory metastatic breast cancer.

CONTRAINDICATIONS

Conventional Doxorubicin:

Severe myocardial insufficiency, recent myocardial infarction (occurring within the last 4 to 6 weeks), severe persistent drug-induced myelosuppression, severe hepatic impairment (Child-Pugh Class C or serum bilirubin level greater than 5 mg/dL).

All Doxorubicins:

History of hypersensitivity to conventional or liposomal formulations of doxorubicin or to their components.

PRECAUTIONS

All Doxorubicins:

Follow guidelines for handling cytotoxic agents and patient excreta. Precautions recommended for up to 5 days after a dose. See Appendix A, p. 1308. ■ Usually administered by or under the direction of a physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ ***Do Not Substitute*** Doxil for conventional doxorubicin. Severe side effects have resulted. Differences in liposomal products as well as conventional products can substantially affect the functional properties of these agents; do not substitute one agent for another. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, hepatic impairment, previous treatment with other anthracyclines (e.g., daunorubicin), anthracenediones (e.g., mitoxantrone), other cardiotoxic agents (e.g., bleomycin), concurrent cyclophosphamide therapy, or radiation therapy encompassing the heart; risk of cardiotoxicity increased and may occur at lower doses. ■ All forms of doxorubicin may cause cardiotoxicity. May be manifest by acute (e.g., arrhythmias, including life-threatening arrhythmias, ECG abnormalities) or delayed (e.g., reduction in LVEF, CHF) events. Life-threatening or fatal left ventricular failure may occur during therapy or months after therapy is completed. Cardiotoxicity occurs with increasing frequency as cumulative doses increase above 300 mg/M^2. The risk of developing CHF increases rapidly with increasing total cumulative doses above 400 mg/M^2; see Antidote. Prior use of other anthracyclines or anthracenediones should be included in calculations of total cumulative dose. Patients with active or dormant cardiovascular disease or patients who have received radiotherapy to the mediastinal area or concomitant therapy with other anthracyclines (e.g., daunorubicin, idarubicin), anthracenediones, or other cardiotoxic agents (e.g., bleomycin, cyclophosphamide, mitoxantrone, mitomycin C, trastuzumab) may be at greater risk. Patients receiving doxorubicin after stopping treatment with trastuzumab may also be at an increased risk of developing cardiotoxicity. Trastuzumab may persist in the circulation for up to 7 months. When possible, avoid anthracycline-based therapy for up to 7 months after stopping trastuzumab. If anthracyclines are used before this time, carefully monitor cardiac function. Consider the use of dexrazoxane to reduce the incidence and severity of cardiomyopathy due to doxorubicin in patients who have received a cumulative dose of 300 mg/M^2 and who will continue to receive doxorubicin. ■ May cause severe myelosuppression resulting in serious infection, septic shock, required transfusions, hospitalization, hemorrhage, and death. ■ See Maternal/Child and Side Effects.

Conventional Doxorubicin:

In addition to cardiomyopathy, pericarditis and myocarditis have been reported during or after therapy with doxorubicin. ■ Secondary acute myelogenous leukemia (AML) and myelodysplastic syndrome (MDS) have been reported and generally occur within 1 to 3 years of treatment. ■ Tumor lysis syndrome may occur; see Monitor.

Doxil:

Benefits must outweigh risks if Doxil is used in patients with a history of cardiovascular disease. ■ Serious, life-threatening and fatal infusion-related reactions and serious, sometimes life-threatening or fatal hypersensitivity/anaphylactoid-like reactions have been reported; see Monitor. ■ Has caused hand-foot syndrome (HFS). Incidence may be increased with higher doses or increased frequency. Generally seen after 2 or 3 cycles, but may occur earlier. May be severe and require a dose adjustment or discontinuation of Doxil. ■ Secondary oral cancers, primarily squamous cell carcinoma, have been reported in patients who have received Doxil for a year or longer. Malignancies have been diagnosed both during treatment and up to 6 years after completion of therapy. ■ Severe, additive myelosuppression may occur in Kaposi's sarcoma patients and may be dose limiting.

Monitor:

All Doxorubicins:

Monitoring of CBC including differential and platelet count, uric acid levels, electrolytes, liver function (AST, ALT, alkaline phosphatase, and bilirubin), kidney function, ECG, chest x-ray, echocardiogram, and left ventricular ejection fraction (LVEF) is necessary before and during therapy. At a minimum, CBC with platelets should be monitored before each dose. Testing for renal and hepatic function may also be indicated; see Dose Adjustments. ■ Observe for S/S of cardiotoxicity (e.g., fast or irregular HR, shortness of breath, swelling of the feet or lower legs). Endomyocardial biopsy or gated radionuclide scans have been used to monitor potential cardiac toxicity. Increase frequency of assessment as cumulative dose exceeds 300 mg/M^2. Use same method of assessment of LVEF at all time points. ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Use of prophylactic antibiotics may be indicated pending C/S in a febrile, neutropenic patient. Sepsis in a neutropenic patient has resulted in discontinuation of treatment and, in rare cases, death. ■ Prophylactic antiemetics are indicated. ■ See Drug/Lab Interactions.

Conventional Doxorubicin:

Monitor for tumor lysis syndrome. S/S include hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure. Prevent or alleviate tumor lysis syndrome with appropriate supportive and pharmacologic measures. ■ Maintain adequate hydration. ■ Uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may prevent formation of uric acid crystals. ■ Use only large veins. Avoid veins over joints or in extremities with compromised venous or lymphatic drainage. Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. ***Extravasation may occur with or without stinging or burning and even if blood returns well on aspiration of infusion needle***. Observe and touch site frequently to feel air and/or liquid under the skin. If extravasation occurs, discontinue injection; use another vein; see Antidote.

Doxil:

Monitor for S/S of acute infusion reactions and/or hypersensitivity (e.g., apnea, asthma, back pain, bronchospasm, chills, cyanosis, facial swelling, fever, flushing, headache, hypotension, pruritus, rash, shortness of breath, syncope, tachycardia, tightness in the chest or throat). The majority of infusion-related reactions occur during the first infusion. ■ Monitor for HFS (skin eruptions characterized by swelling, pain, erythema, and possible desquamation of the skin on the hands and feet). ■ Monitor for the presence of oral ulceration or oral discomfort that may be indicative of secondary oral cancer. ■ Extravasation may cause irritation at infusion site. Discontinue and use another vein.

Patient Education:

All Doxorubicins:

Urine and other body fluids will be reddish for several days (from dye, not hematuria). ■ Effective birth control required for females of reproductive potential during treatment and for 6 months after the last dose and for males with female partners of reproductive potential during treatment and for 3 months after the last dose. May cause infertility in both men and women. ■ Effects may be additive with current medications. Review all medications (prescription and nonprescription) with nurse and/or physician. ■ Promptly report cough, fast heartbeat, shortness of breath, and/or swelling of the feet or lower legs. ■ Report S/S of infection (e.g., chills, fever, painful urination), stomatitis, bothersome side effects, or any unusual bleeding (e.g., bruising, tarry stools). ■ Report IV site burning, stinging, puffiness, or the feeling of liquid under the skin and any other side effects promptly. ■ Report tingling, burning, redness, flaking, swelling, blisters or small sores on the palms of hands or soles of feet. ■ See Precautions. ■ See Appendix D, p. 1311.

Maternal/Child:

All Doxorubicins:

Avoid pregnancy. Based on its mechanism of action, can cause fetal harm. ■ Has been used only when benefits outweigh risks (see Doxil). ■ Discontinue breast-feeding during treatment and for 10 days after the final dose.

Conventional Doxorubicin:

Treatment during childhood may result in abnormal cardiac function. ■ Infants and children are at increased risk for developing delayed cardiotoxicity; follow-up cardiac evaluation is recommended; see Precautions. ■ In infants under 2 years of age, doxorubicin clearance is similar to adults, but clearance may be increased in pediatric patients over 2 years of age. ■ May contribute to prepubertal growth failure and/or gonadal impairment (which is usually temporary). ■ See Precautions, extended recommendations for handling patient excreta.

Doxil:

If use during pregnancy is considered, avoid use during the first trimester. ■ Safety for use in pediatric patients not established.

Elderly:

All Doxorubicins:

Response similar to that seen in younger adults, but greater sensitivity of some older individuals cannot be ruled out. ■ Cardiotoxicity and myelotoxicity may be more severe in patients over 70 years of age. ■ Consider age-related organ impairment and concomitant disease and/or drug therapy; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Studies not yet completed for Doxil; interactions may be similar to conventional doxorubicins. ■ Doxorubicin is a major substrate for cytochrome P_{450} CYP3A4 and CYP2D6 and P-glycoprotein. Clinically significant interactions have been reported with inhibitors of CYP3A4 and CYP2D6 and P-glycoprotein (e.g., **verapamil**), resulting in increased concentrations and clinical effects of doxorubicin. Inducers of CYP3A4 (e.g., **phenobarbital, phenytoin, St. John's wort**) and P-glycoprotein may decrease the concentration of doxorubicin. Avoid concurrent use with **inhibitors or inducers of CYP3A4 and CYP2D6 and P-glycoprotein.** ■ Avoid concurrent administration of doxorubicin and **trastuzumab**; results in an increased risk of cardiac dysfunction. Patients receiving doxorubicin after stopping treatment with trastuzumab may also be at an increased risk of developing cardiotoxicity. Trastuzumab may persist in the circulation for up to 7 months. When possible, avoid anthracycline-based therapy for up to 7 months after stopping trastuzumab. If anthracyclines are used before this time, carefully monitor cardiac function. ■ May exacerbate **cyclophosphamide**-induced hemorrhagic cystitis or increase hepatotoxicity of **6-mercaptopurine.** ■ May increase bone marrow toxicity of **other chemotherapeutic agents and radiation.** ■ **Barbiturates** increase clearance and decrease effects. ■ May decrease serum levels of **digoxin.** ■ May decrease serum levels of **anticonvulsants** (e.g., phenytoin, carbamazepine, valproate). ■ Risk of cardiotoxicity increased in patients previously treated with **other anthracyclines** (e.g., idarubicin) **and/or radiation encompassing the heart.** ■ **Cyclosporine and streptozocin** may decrease clearance and increase toxicity of doxorubicin. ■ **Paclitaxel** appears to decrease the clearance of doxorubicin. Administration of doxorubicin before paclitaxel is recommended to prevent increased toxicity. ■ Coadministration with high-dose **progesterone** may increase doxorubicin toxicity. ■ Many drug interactions possible; observe patient closely. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Increased toxicity to mucosa, myocardium, skin (including redness and exfoliative changes), and liver possible when given concurrently **with or after radiation.** ■ **Dexrazoxane** is given with doxorubicin to reduce cardiotoxic effects. May also decrease antitumor effectiveness if given before a cumulative dose of doxorubicin 300 mg/M² is reached or other chemotherapeutic agents are included in the protocol (e.g., fluorouracil). ■ See Precautions.

SIDE EFFECTS

All Doxorubicins:

Abdominal pain; alopecia (complete); anorexia; asthenia; bone marrow suppression (e.g., anemia, hypochromic anemia, leukopenia, neutropenia [ANC less than 1,000/mm³], thrombocytopenia may be dose-limiting); cardiac toxicity (e.g., CHF); constipation; decreased serum calcium; depressed QRS voltage; diarrhea; dry skin; esophagitis; fatigue; fever; gonadal suppression; headache; hyperpigmentation of nail beds and dermal creases; hypersensitivity reactions (including life-threatening or fatal anaphylaxis); hyperuricemia; increase in alkaline phosphatase, ALT, AST, bilirubin, BUN, glucose, SCr; infection; mucositis; nausea; oral moniliasis; paresthesia; prolonged PT; rash; recall of skin reactions due to prior radiotherapy; stomatitis; weakness; vomiting.

Doxil:

In addition to all of the above, acute infusion reactions, hand-foot syndrome, secondary oral cancer. ***Kaposi's sarcoma*** patients may be taking numerous other drugs that may confuse the overall side effect picture (e.g., didanosine [ddl], stavudine [D4T], sulfamethoxazole/trimethoprim, zalcitabine [ddC], zidovudine [AZT, Retrovir]).

Post-Marketing:

Muscle spasms, myelogenous leukemia, pulmonary embolism, and skin and subcutaneous tissue disorders (e.g., erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis).

Overdose:

All Doxorubicins:

Increase in bone marrow suppression and mucositis.

ANTIDOTE

All Doxorubicins:

Most side effects will either be tolerated or treated symptomatically. Keep the physician informed. Bone marrow toxicity may require cessation of therapy. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Acute cardiac failure occurs suddenly (most common when total cumulative dosage approaches 550 mg/M²) and frequently does not respond to currently available treatment (digoxin, diuretics [e.g., furosemide], ACE inhibitors [e.g., enalapril]). Close monitoring of accumulated dosage, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal cardiac side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Treat hypersensitivity reactions as required; discontinue therapy if severe.

Conventional Doxorubicin:

Discontinue doxorubicin in patients who develop signs or symptoms of cardiomyopathy. For extravasation, attempt to aspirate extravasated fluid before removing needle. Do not flush line or apply pressure to site. Elevate the extremity and apply ice for 15 minutes four times a day for 3 days. If appropriate, administer dexrazoxane at the site of extravasation as soon as possible and within the first 6 hours after extravasation. Site should be observed promptly by a reconstructive surgeon.

Doxil:

In addition to all of the above, treatment may have to be interrupted or discontinued for severe hand-foot syndrome or acute infusion reactions. Infusion reactions may resolve with slowing of infusion rate. May be able to control hand-foot syndrome by allowing it to resolve and by increasing intervals between subsequent cycles. For extravasation, discontinue infusion and apply ice over site for 30 minutes to alleviate local reaction.

DOXYCYCLINE HYCLATE

(dox-ih-**SYE**-kleen **HI**-klayt)
Doxy 100, Doxy 200, Vibramycin
Antibacterial (tetracycline)
Antiprotozoal
Antimalarial
pH 1.8 to 3.3

USUAL DOSE

Pretreatment:

Verify pregnancy status; see Contraindications.

Parenteral therapy is indicated only when oral therapy is not indicated. Transfer to oral therapy as soon as practical.

Adults and Pediatric Patients Weighing 45 kg or More

200 mg the first day in one or two infusions followed by 100 to 200 mg/24 hr on subsequent days with 200 mg administered in one or two infusions. Depends on severity of the infection.

Primary and secondary syphilis:

300 mg daily for at least 10 days.

Acute pelvic inflammatory disease:

100 mg every 12 hours. Used in combination with cefoxitin 2 Gm every 6 hours.

Treatment of inhalational anthrax (postexposure):

100 mg every 12 hours. Continue therapy for 60 days.

PEDIATRIC DOSE

All Doses are For Pediatric Patients Weighing Less Than 45 kg

4.4 mg/kg of body weight on the first day of treatment, administered in one or two infusions. Subsequent daily dose is 2.2 mg/kg to 4.4 mg/kg of body weight/day given as one or two infusions depending on the severity of the infection. Transfer to oral therapy as soon as practical. Do not exceed adult dose. See Maternal/Child.

Treatment of inhalational anthrax (postexposure):

2.2 mg/kg of body weight every 12 hours. Do not exceed adult dose. Continue therapy for 60 days.

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

Each 100 mg or fraction thereof is diluted with 10 mL of SWFI or NS (may also be reconstituted with any of the **compatible** solutions listed for further dilution). Further dilute each 100 mg (10 mL) with 100 to 1,000 mL of a **compatible** infusion solution such as NS, D5W, R, LR, D5LR, 10% invert sugar in water, Normosol-M or Normosol-R in 5% dextrose in water, or other **compatible** solutions (see literature). Recommended concentrations 0.1 to 1 mg/mL. 100 mg in 1,000 mL of solution equals 0.1 mg/mL, 100 mg in 100 mL equals 1 mg/mL.

Storage:

Store vials at CRT in carton; protect from light. Stable for 48 hours when diluted with NS or D5W to concentrations between 0.1 and 1 mg/mL and stored at 25° C (77° F). Protect from direct sunlight during storage and infusion. These dilutions may be stored for 72 hours if refrigerated and protected from sunlight *and* artificial light. Infusion must be completed within 12 hours. Solutions must be used within these time periods or discarded. See manufacturer's prescribing information for stability data when mixed with other solutions.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Avoid rapid administration. Duration of infusion may vary with dose but is usually 1 to 4 hours. The recommended minimum infusion time for 100 mg of a 0.5 mg/mL solution is 1 hour.

ACTIONS

A broad-spectrum tetracycline antibiotic, bacteriostatic against many microorganisms, including gram-positive, gram-negative, anaerobic, atypical, and parasitic organisms. Thought to interfere with the protein synthesis of microorganisms. Doxycycline is well distributed in most body tissues and is highly bound to plasma protein. Half-life is 18 to 22 hours. Concentrated by the liver in the bile and excreted in urine and feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Infections caused by susceptible strains of several microorganisms, including many gram-positive, gram-negative, anaerobic, atypical bacteria (e.g., *Rickettsia, Chlamydia, Chlamydophila, Mycoplasma*) or parasites (e.g., *Balantidium coli, Entamoeba* species).Types of infections treated may include GU infections, including those caused by *Chlamydia trachomatis* and *Neisseria gonorrhoeae;* respiratory tract infections, including mycoplasma pneumonia; skin and soft tissue infections; syphilis; and others. ■ To substitute for contraindicated penicillin or sulfonamide therapy. ■ Adjunct to amebicides in acute intestinal amebiasis. ■ Prevention and/or treatment of anthrax in all its forms, including cutaneous and inhalation anthrax postexposure.

CONTRAINDICATIONS

Known hypersensitivity to tetracyclines. Not recommended in pediatric patients under 8 years or in pregnancy or breast-feeding.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of the causative organism to doxycycline. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, doxycycline should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with doxycycline. ■ Initiate oral therapy as soon as possible. ■ Cross-resistance with other tetracyclines is common. ■ Intracranial hypertension (IH, pseudotumor cerebri) has been associated with the use of tetracyclines, including doxycycline. Clinical manifestations include headache, blurred vision, diplopia, vision loss, and papilledema. Women of childbearing age who are overweight or have a history of IH are at greater risk for developing tetracycline-associated IH. ■ In venereal diseases in which coexistent syphilis is suspected, perform a dark-field examination before initiating treatment. Repeat blood serology monthly for at least 4 months. ■ The antianabolic action of tetracyclines may cause an increase in BUN. Studies to date indicate that this does not occur with the use of doxycycline in patients with impaired renal function. ■ All infections due to group A beta-hemolytic streptococci should be treated for at least 10 days.

Monitor:

Determine absolute patency of vein and avoid extravasation; thrombophlebitis may occur. ■ Monitor for S/S of intracranial hypertension. If visual symptoms develop during treatment with doxycycline, prompt ophthalmologic evaluation is warranted. Intracranial pressure can remain elevated for weeks after drug cessation. Continue ophthalmologic monitoring until patient stabilizes. Permanent vision loss can occur. ■ Monitor hematopoietic, renal, and hepatic studies periodically in long-term therapy. ■ Monitor for S/S of hypersensitivity reactions. ■ See Drug/Lab Interactions.

Patient Education:

Report severe diarrhea, S/S of hypersensitivity reactions, or S/S of IH promptly. ■ Alert patient to photosensitive skin reaction. ■ Consider birth control options.

Maternal/Child:

Avoid pregnancy; see Contraindications. ■ May cause retardation of skeletal development in the fetus and in infants. ■ Exposure during the last half of pregnancy, infancy, and childhood to the age of 8 years may cause permanent discoloration of the teeth. Avoid exposure in this age-group unless potential benefits are expected to outweigh the risks in severe or life-threatening infections (e.g., anthrax, Rocky Mountain spotted fever), particularly when there are no alternative therapies. ■ Discontinue breast-feeding.

DRUG/LAB INTERACTIONS

May render **oral contraceptives** less effective; may result in pregnancy or breakthrough bleeding. ■ Interferes with bactericidal action of **all penicillins** (e.g., ampicillin, oxacillin). Avoid concomitant use. ■ Serum levels decreased by **barbiturates, carbamazepine, hydantoins** (e.g., phenytoin), and others. ■ May depress **plasma prothrombin activity;** a reduction in **anticoagulant** dose may be indicated. ■ Avoid concomitant use with **isotretinoin**.

SIDE EFFECTS

Relatively nontoxic in average doses. More toxic in large doses or if given too rapidly. Anogenital lesions, anorexia, blood dyscrasias (eosinophilia, hemolytic anemia, neutropenia, thrombocytopenia), diarrhea, dysphagia, elevated BUN, enterocolitis, glossitis, nausea, skin rashes, vomiting.

Major:

Hypersensitivity reactions (including anaphylaxis, angioneurotic edema, exacerbation of systemic lupus erythematosus, pericarditis, and urticaria), bulging fontanels in infants, CDAD, drug rash with eosinophilia and systemic symptoms (DRESS), exfoliative dermatitis, hepatotoxicity, intracranial hypertension (blurred vision, diplopia, headache, papilledema, vision loss), photosensitivity, systemic candidiasis, thrombophlebitis.

ANTIDOTE

Notify the physician of all side effects. If minor side effects are progressive or any major side effect occurs, discontinue the drug, treat hypersensitivity reactions as indicated, or resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of doxycycline. Treat antibiotic-related CDAD with fluid, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. Not removed by hemodialysis.

DROPERIDOL BBW

(droh-**PER**-ih-dohl)
Inapsine
Antiemetic
Anesthesia adjunct
pH 3 to 3.8

USUAL DOSE

Pretreatment:

Electrolyte correction indicated; see Precautions. Baseline ECG required; see Monitor.

May cause serious proarrhythmic effects and death; reserve use to patients for whom other treatments are ineffective or inappropriate. Dose should be individualized and initiated at a low dose. Adjust upward, with caution, to achieve the desired effect. Consider age, body weight, physical status, underlying pathologic conditions, use of other drugs, type of anesthesia to be used, and surgical procedure involved; see Precautions. Maximum recommended initial dose is 2.5 mg. Additional 1.25-mg doses may be given to achieve the desired effect but should be used only if the potential benefit outweighs the potential risk.

Prevention of perioperative nausea and vomiting:

Dose should be individualized; maximum initial dose is 2.5 mg by slow IV injection. Additional 1.25-mg doses may be given with caution to achieve desired effect only if benefits outweigh potential risk. 0.625 to 1.25 mg has been shown to have an effect similar to ondansetron (Zofran) 4 mg.

PEDIATRIC DOSE

Prevention of perioperative nausea and vomiting, pediatric patients 2 to 12 years:

The maximum recommended dose is 0.1 mg/kg (100 mcg/kg). Another source suggests 0.03 to 0.07 mg/kg/dose (30 to 70 mcg/kg/dose) over 2 minutes or up to 0.1 mg/kg/dose with caution to achieve desired effect only if benefits outweigh potential risk and total dose does not exceed 2.5 mg. May be given IM or IV. See Maternal/Child.

DOSE ADJUSTMENTS

Initiate at a low dose and adjust upward with caution to achieve the desired effect. ■ Reduce dose of narcotics and all CNS depressants to one-fourth or one-third of usual dose before, during, and for 24 hours after injection of droperidol. ■ If other CNS depressants (e.g., narcotics) have been given previously, reduce dose of droperidol. ■ Reduce dose for elderly, debilitated, and poor-risk patients and those with impaired kidney or liver function.

DILUTION

May be given undiluted. Give through Y-tube or three-way stopcock of the infusion set. May be added to a convenient volume of selected infusion solutions (D5W, NS, or LR).

Filters:

No data available from manufacturer.

Storage:

Store vials at CRT; protect from light. Diluted solutions stable at CRT for at least 48 hours (up to 7 days in selected solutions; see literature).

COMPATIBILITY

Manufacturer states, “Will precipitate if mixed with barbiturates” (e.g., phenobarbital). Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Adults: 2.5 mg or fraction thereof over 1 to 2 minutes. ***Pediatric patients:*** A single dose or fraction thereof over a minimum of 2 minutes.

Infusion:

Titrate by dose and desired patient response. Do not exceed rate for IV injection.

ACTIONS

An antianxiety agent that produces marked tranquilization and sedation. Has an antiemetic action also. It produces mild alpha-adrenergic blockade and produces peripheral vascular dilation. May decrease an abnormally high pulmonary arterial pressure. A dose-dependent and significant QT prolongation at all dose levels (0.1, 0.175, and 0.25 mg/kg) has been observed within 10 minutes of administration in patients without known cardiac disease. Effective in 3 to 10 minutes with maximum results in 30 minutes. Lasts 2 to 4 hours. Some effects persist for 12 hours. Metabolized in the liver. Excreted in urine and feces. Crosses placental barrier very slowly. Secreted in breast milk.

INDICATIONS AND USES

To reduce the incidence of nausea and vomiting associated with surgical and diagnostic procedures.

Unlabeled uses:

Antiemetic in cancer chemotherapy including potent emetic agents (e.g., cisplatin). ■ Treatment of acute psychotic episodes manifested by severe agitation and combativeness. ■ Adjunct to local or general anesthesia.

CONTRAINDICATIONS

Known hypersensitivity to droperidol or other butyrophenones (e.g., haloperidol [Haldol]) and patients with known or suspected QT prolongation, including those with congenital long QT syndrome.

PRECAUTIONS

Use of agents other than droperidol is recommended. ■ QT prolongation and torsades de pointes have been reported with doses at or below those recommended. Some cases have occurred in patients with no known risk factors for QT prolongation, and some cases have been fatal. ■ Use with extreme caution in patients who may be at risk for development of prolonged QT syndrome (e.g., clinically significant bradycardia [less than 50 bpm]; CHF or any clinically significant cardiac disease; use of a diuretic; treatment with Class Ia antiarrhythmics and/or Class III antiarrhythmics; treatment with MAO inhibitors [e.g., selegiline]; concomitant treatment with other drug products known to prolong the QT interval; electrolyte imbalance, in particular hypokalemia or hypomagnesemia; alcoholism; or concomitant treatment with drugs that may cause electrolyte imbalance or hypovolemia). See Drug Interactions. ■ Other risk factors may include patients over 65 years of age, alcohol abuse, pheochromocytoma, and the use of agents such as benzodiazepines, volatile anesthetics, and IV opiates. ■ Correct hypokalemia and/or hypomagnesemia before administration. ■ When used without a general anesthetic, topical anesthesia is still required when appropriate (e.g., bronchoscopy). ■ May worsen symptoms of Parkinson’s disease.

Monitor:

A potent drug. Obtain a baseline ECG on all patients. Do not administer droperidol if a prolonged QT interval exists (QTc greater than 440 msec for males or 450 msec for females). ■ Monitor VS and ECG closely. Monitor for palpitations, syncope, and/or other symptoms of irregular cardiac rhythm and evaluate promptly. ■ Resuscitation equipment, a narcotic antagonist (if a narcotic has been used concurrently), IV infusion line, IV fluids, and equipment and drugs to manage emergency situations must be readily available. ■ In patients for whom the benefit is believed to outweigh the risks of potentially serious arrhythmias, monitor for arrhythmias during the treatment and for 2 to 3 hours after treatment. ■ Orthostatic hypotension is common; move and position patients with care. ■ EEG pattern may be slow in returning to normal postoperatively.

See Precautions.

Patient Education:

Avoid activities that require alertness for 24 hours after receiving droperidol. ■ Do not drink alcoholic beverages or take other CNS depressants (e.g., antihistamines, pain medications, sleeping pills) for 24 hours after receiving droperidol.

Maternal/Child:

Category C: safety for use during pregnancy not established; is rarely used. An exception is selected use during cesarean section; it has also been used to treat hyperemesis gravidarum (no longer recommended). ■ Is secreted in breast milk; avoid breast-feeding. ■ Pediatric patients may be more susceptible to extrapyramidal side effects, especially acute dystonic reactions. ■ Safety for use in pediatric patients under 2 years not established.

Elderly:

See Dose Adjustments. ■ More likely to experience hypotension, excessive sedation, and prolonged QT syndrome.

DRUG/LAB INTERACTIONS

Concurrent use with **fentanyl** may cause hypotension and decrease pulmonary arterial pressure. ■ May cause precipitous hypotension with **epinephrine.** ■ Use caution with **other CNS depressant drugs** (e.g., barbiturates, tranquilizers, opioids, and general anesthetics); may have additive or potentiating effects **with droperidol;** see Dose Adjustments. ■ Increased risk of QT prolongation and torsades de pointes with **other drugs known to increase the QT interval** (e.g., **Class Ia antiarrhythmics** [e.g., disopyramide, procainamide, quinidine] **and/or Class III antiarrhythmics** [e.g., amiodarone, dofetilide, ibutilide, sotalol], **anticonvulsants, antidepressants, antihistamines** [e.g., diphenhydramine], **antimalarials, antineoplastics, azole antifungal agents, calcium channel blockers, fluoroquinolones, other neuroleptics** [e.g., haloperidol, lithium], **and many others**); see Precautions. ■ Concurrent administration with **volatile anesthetics, benzodiazepines**, or **IV opiates** may produce prolonged QT syndrome. Initiate therapy at a low dose and adjust with caution. ■ Concomitant treatment with **diuretics, laxatives, steroids with mineralocorticoid potential** (e.g., hydrocortisone) may cause hypovolemia and/or induce hypokalemia or hypomagnesemia. ■ Concurrent use with **other agents that produce hypotension** may cause orthostatic hypotension; risk is increased with **agents that produce vasodilation** (e.g., amiodarone, milrinone, nitroprusside sodium, nicardipine). ■ See Dose Adjustments and Precautions.

SIDE EFFECTS

Common:

Abnormal EEG, chills, dizziness, hallucinations, hypotension, restlessness, shivering, tachycardia.

Major/overdose:

Apnea; cardiac arrest; extrapyramidal symptoms; hypotension (severe); neuroleptic malignant syndrome (altered consciousness, muscle rigidity, and autonomic instability); palpitations, syncope, or other symptoms of irregular cardiac rhythm; QT prolongation and torsades de pointes; respiratory depression; ventricular tachycardia; death.

ANTIDOTE

Notify the physician of any side effect. Minor side effects will probably be transient; for major side effects discontinue the drug, treat symptomatically, and notify the physician. Treat hypotension with fluid therapy (rule out hypovolemia) and vasopressors. Phenylephrine may help to counteract the alpha-blocking effects of droperidol. Epinephrine is contraindicated for hypotension. Further hypotension will occur. Treat extrapyramidal symptoms with benztropine mesylate or diphenhydramine. Treat cardiac arrhythmias as indicated (e.g., magnesium sulfate for torsades de pointes, lidocaine for ventricular tachycardia). An increase in temperature, HR, or CO_2 production may be symptoms of neuroleptic malignant syndrome or malignant hyperpyrexia. Consider prompt treatment with dantrolene. Resuscitate as necessary.

DURVALUMAB

(dur-**VAL**-ue-mab)
Imfinzi
Antineoplastic agent
Monoclonal antibody (Anti-PD-L1)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

May be considered in subsequent infusions in patients who experience a Grade 1 or 2 infusion-related reaction.

Urothelial carcinoma:

10 mg/kg as an IV infusion over 60 minutes every 2 weeks until disease progression or unacceptable toxicity.

Non–small-cell lung cancer:

10 mg/kg as an IV infusion over 60 minutes every 2 weeks until disease progression, unacceptable toxicity, or a maximum of 12 months.

DOSE ADJUSTMENTS

No dose reductions are recommended for durvalumab. Withhold and/or discontinue durvalumab to manage adverse reactions as described in the following chart.

Recommended Treatment Modifications for Durvalumab Adverse Reactions

Treatment-Related Adverse Reaction	Severity of Adverse Reaction[a]	Durvalumab Treatment Modification	Corticosteroid Treatment Unless Otherwise Specified
Pneumonitis	Grade 2	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	Grade 3 or 4	Permanently discontinue	Initial dose of 1 to 4 mg/kg/day prednisone or equivalent followed by a taper
Hepatitis	ALT or AST >3 but ≤8 × ULN or total bilirubin >1.5 but ≤5 × ULN	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	ALT or AST >8 × ULN or total bilirubin >5 × ULN	Permanently discontinue	
	OR		

	Concurrent ALT or AST >3 × ULN and total bilirubin >2 × ULN with no other cause		
Colitis or diarrhea	Grade 2	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	Grade 3 or 4	Permanently discontinue	
Hypothyroidism	Grades 2 to 4		Initiate thyroid hormone replacement as clinically indicated
Hyperthyroidism	Grades 2 to 4	Withhold dose until clinically stable	Medical management
Adrenal insufficiency, hypophysitis/hypopituitarism	Grades 2 to 4	Withhold dose until clinically stable	Initiate 1 to 2 mg/kg/day prednisone or equivalent followed by a taper and hormone replacement as clinically indicated
Type 1 diabetes mellitus	Grades 2 to 4	Withhold dose until clinically stable	Initiate treatment with insulin as clinically indicated
Nephritis	Creatinine >1.5 to 3 × ULN	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	Creatinine >3 × ULN	Permanently discontinue	
Rash or dermatitis	Grade 2 for >1 week or Grade 3	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Consider initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	Grade 4	Permanently discontinue	
Infection	Grade 3 or 4	Withhold dose until clinically stable	Treat with anti-infectives for suspected or confirmed infections

Infusion-related reactions	Grade 1 or 2	Interrupt or slow the rate of the infusion	Consider premedications with subsequent doses
	Grade 3 or 4	Permanently discontinue	
Other immune-mediated adverse reactions	Grade 3	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than 10 mg/day (or equivalent)[b]	Initial dose of 1 to 2 mg/kg/day prednisone or equivalent followed by a taper
	Grade 4	Permanently discontinue	Consider initial dose of 1 to 4 mg/kg/day prednisone or equivalent followed by a taper
Persistent Grade 2 or 3 adverse reactions (excluding endocrinopathies)	Grade 2 or 3 adverse reaction that does not recover to Grade 0 or 1 within 12 weeks after last durvalumab dose	Permanently discontinue	
Inability to taper corticosteroids	Inability to reduce to prednisone ≤10 mg/day (or equivalent) within 12 weeks after last durvalumab dose	Permanently discontinue	
Recurrent Grade 3 or 4 adverse reaction	Recurrent Grade 3 or 4 (severe or life-threatening) adverse reaction	Permanently discontinue	

[a] Toxicity was graded per the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), Version 4.03.

[b] Based on the severity of the adverse reactions, durvalumab should be withheld and corticosteroids administered. For adverse reactions that do not result in permanent discontinuation, resume treatment when adverse reaction returns to ≤ Grade 1 and the corticosteroid dose has been reduced to ≤10 mg prednisone or equivalent per day.

■ No pharmacokinetic differences were observed in patient subgroups defined by age, body weight, gender, albumin levels, LDH levels, creatinine levels, race, soluble PD-L1, tumor type, mild renal impairment (CrCl 60 to 89 mL/min), moderate renal impairment (CrCl 30 to 59 mL/min), mild hepatic impairment (bilirubin less than or equal to the ULN and AST greater than the ULN or bilirubin greater than 1 to 1.5 times the ULN and any AST), or ECOG performance status. ■ The effect of severe renal impairment (CrCl 15 to 29 mL/min), moderate hepatic impairment (bilirubin greater than 1.5 to 3 times the ULN and any AST), or severe hepatic impairment (bilirubin greater than 3 times the ULN and any AST) on the pharmacokinetics of durvalumab is unknown. ■ See Monitor and Precautions.

DILUTION

Available as a 120 mg/2.4 mL (50 mg/mL) and 500 mg/10 mL (50 mg/mL), clear to opalescent, colorless to slightly yellow solution in a single-dose vial. ***Do not shake***. Withdraw the required volume from the vial(s) and transfer into an IV bag containing NS or D5W. Mix diluted solution by gentle inversion. ***Do not shake.*** The final concentration of the diluted solution should be between 1 and 15 mg/mL.

Filters:

Use of sterile, nonpyrogenic, low–protein-binding, in-line filter (pore size of 0.2 or 0.22 micron) required.

Storage:

Before use, refrigerate vials at 36° to 46° F (2° to 8° C) in original carton to protect from light. ***Do not freeze or shake.*** Immediate use of prepared solution is preferred. If solution is not administered immediately, the total time from vial puncture to start of administration should not exceed 24 hours if stored in a refrigerator or 4 hours if stored at RT. Discard any partially used or empty vials.

COMPATIBILITY

Manufacturer states, “Do not coadminister other drugs through the same infusion line.”

RATE OF ADMINISTRATION

A single dose equally distributed over 60 minutes through an IV line containing a sterile, nonpyrogenic, low–protein-binding, in-line filter (pore size of 0.2 or 0.22 micron). Interrupt or slow the rate of infusion for mild or moderate infusion-related reactions; see Dose Adjustments.

ACTIONS

A human IgG1 kappa monoclonal antibody. Durvalumab is a programmed cell death–ligand 1 (PD-L1) blocking antibody. Durvalumab binds PD-L1 and blocks the interaction between PD-L1 and its receptors PD-1 and B7.1. This interaction releases the inhibitory effects of PD-L1 on the immune response without inducing antibody-dependent cell-mediated cytotoxicity. This results in the restoration of immune responses, including antitumor immune responses. Terminal half-life is 18 days.

INDICATIONS AND USES

Treatment of patients with locally advanced or metastatic urothelial carcinoma who have disease progression during or following platinum-containing chemotherapy or who have disease progression within 12 months of neoadjuvant or adjuvant treatment with platinum-containing therapy. (This indication is approved under accelerated approval based on tumor response and duration of response. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trials.) ■ Treatment of patients with unresectable Stage III non–small-cell lung cancer (NSCLC) whose disease has not progressed following concurrent platinum-based chemotherapy and radiation therapy.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Immune-mediated pneumonitis and interstitial lung disease with fatalities have been reported. ■ Immune-mediated hepatitis with fatalities has been reported. ■ Durvalumab can cause immune-mediated colitis. ■ Durvalumab can cause immune-mediated endocrinopathies (e.g., adrenal insufficiency, thyroid disorders [hypothyroidism/hyperthyroidism], type 1 diabetes mellitus, and hypophysitis/hypopituitarism). ■ Durvalumab can cause immune-mediated thyroid disorders. Thyroid disorders can occur at any time during treatment. Manage hypothyroidism with hormone replacement therapy, if indicated. Initiate medical management for control of hyperthyroidism, if indicated. ■ Durvalumab can cause diabetes, including type 1 diabetes mellitus. Withhold durvalumab and administer antihyperglycemics or insulin in patients with severe or life-threatening hyperglycemia. ■ Immune-mediated nephritis with fatalities has been reported. ■ Immune-mediated dermatologic reactions (e.g., bullous dermatitis, Stevens-Johnson syndrome [SJS]/toxic epidermal necrolysis [TEN]) have been reported with other products in this class. ■ Durvalumab has caused other immune-mediated adverse reactions, including aseptic meningitis, hemolytic anemia, immune thrombocytopenic purpura, myocarditis, myositis, and ocular inflammatory toxicity (e.g., uveitis and keratitis). Immune-mediated reactions may involve any organ. They usually occur during treatment with durvalumab but may also manifest after discontinuation of therapy; see Dose Adjustments. ■ Serous infections, including fatal cases, have been reported. ■ Severe or life-threatening infusion-related reactions have been reported. ■ A protein substance; has a potential for immunogenicity.

Monitor:

Obtain baseline serum creatinine, serum glucose, liver function tests, and thyroid function tests before initiating treatment and monitor periodically during treatment and as indicated based on clinical evaluation. Repeat serum creatinine and liver function tests before each cycle. ■ Monitor for S/S of pneumonitis. Evaluate patients with suspected pneumonitis with radiographic imaging. ■ Monitor for S/S of colitis. Antidiarrheal agents may be used in addition to corticosteroids and treatment modifications as outlined in Dose Adjustments. ■ Monitor for S/S of adrenal insufficiency during and after treatment. S/S may include fatigue, hyperkalemia, hyponatremia, hypotension, low cortisol concentrations, nausea, and vomiting. Administer corticosteroids and hormone replacement as appropriate for adrenal insufficiency. ■ Monitor for hyperglycemia or other S/S of diabetes. For patients with severe or life-threatening hyperglycemia, resume treatment with durvalumab when metabolic control is achieved with insulin replacement or antihyperglycemics. ■ Monitor for S/S of hypophysitis or hypopituitarism (e.g., fatigue, headache, low levels of the hormones produced by the pituitary gland [adrenocorticotropic hormone (ACTH), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), growth hormone (GH), prolactin]). Administer corticosteroids and hormone replacement as clinically indicated. ■ Monitor for S/S of rash. ■ Monitor for other possible immune-mediated adverse reactions. Evaluate to confirm or rule out an immune-mediated adverse reaction and to exclude other causes. Use of high-dose corticosteroids and/or hormone replacement therapy may be indicated. ■ Monitor for S/S of infection. Initiate treatment with anti-infectives for suspected or confirmed infections. ■ Monitor for S/S of infusion-related reactions, including back pain, chills, dizziness, dyspnea, fever, flushing, hypotension, pruritus, rash, urticaria, and wheezing. Interrupt or slow the rate of infusion in patients with mild or moderate infusion reactions. ■ Administer corticosteroids followed by a corticosteroid taper for Grade 2 or greater colitis, hepatitis, nephritis, pneumonitis, dermatitis, or other immune-mediated reactions; see Precautions and Dose Adjustments.

Patient Education:

Review manufacturer’s medication guide. ■ Avoid pregnancy; females of childbearing potential should use effective contraception during treatment with durvalumab and for at least 3 months after the last dose. ■ Promptly report S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of abdomen, or severe nausea or vomiting). ■ Promptly report S/S of colitis (e.g., blood or mucus in stools, diarrhea, or severe abdominal pain). ■ Promptly report S/S of endocrinopathies (e.g., adrenal insufficiency, diabetes mellitus, hyperthyroidism, hypophysitis, or hypothyroidism). ■ Promptly report S/S of nephritis and renal dysfunction (e.g., blood in urine, decreased urine output, loss of appetite, swelling in ankles, and any other symptoms of renal dysfunction). ■ Promptly report S/S of other possible immune-mediated adverse reactions (e.g., aseptic meningitis, hemolytic anemia, myocarditis, myositis, rash, thrombocytopenic purpura, uveitis, and keratitis). ■ Promptly report S/S of infection (e.g., chills, fever). ■ Promptly report S/S of infusion-related reactions (e.g., chills, fever, hives, and shortness of breath or wheezing).

Maternal/Child:

Based on its mechanism of action, durvalumab can cause fetal harm. Females of reproductive potential should use effective contraception during treatment with durvalumab and for at least 3 months after the last dose. ■ Discontinue breast-feeding during therapy with durvalumab and for at least 3 months after final dose. ■ Safety and effectiveness for use in pediatric patients has not been established.

Elderly:

The majority of patients in studies were 65 years of age or older. Differences between elderly patients and younger patients were not identified.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted.

SIDE EFFECTS

The most common side effects reported were constipation, cough, decreased appetite, dyspnea, fatigue, musculoskeletal pain, nausea, peripheral edema, pneumonitis/radiation pneumonitis, rash, upper respiratory tract infection, and urinary tract infection. The most common Grade 3 or Grade 4 adverse reactions were abdominal pain, dehydration, fatigue, general physical health deterioration, musculoskeletal pain, and urinary tract infection. Other side effects reported were diarrhea/colitis, fever, hypothyroidism, pneumonia, and pruritus. Laboratory abnormalities included anemia; hypercalcemia; hyperglycemia; hyperkalemia; hypermagnesemia; hypoalbuminemia; hypokalemia; hyponatremia; increased alkaline phosphatase, ALT, AST, bilirubin, creatinine, GGT; lymphopenia; and neutropenia. Serious infections, infusion-related reactions, immune-mediated colitis, immune-mediated dermatologic reactions, immune-mediated endocrinopathies, immune-mediated hepatitis, immune-mediated nephritis and renal dysfunction, immune-mediated pneumonitis, and other immune-mediated reactions have occurred.

ANTIDOTE

No overdose information is available. Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated; see Dose Adjustments. For life-threatening infusion reactions, immediately and permanently stop durvalumab and administer appropriate supportive treatment. For less severe infusion reactions, management may involve temporarily stopping the infusion, reducing the infusion rate, and/or administering symptomatic treatment (e.g., IV saline, diphenhydramine, bronchodilators such as albuterol, and acetaminophen). Resuscitate if indicated.

USUAL DOSE

Pretreatment:

A meningococcal vaccine must be administered at least 2 weeks before initial dosing with eculizumab to all patients who have not been previously vaccinated. A booster dose may be required for patients previously vaccinated. Revaccinate according to current medical guidelines. If eculizumab must be initiated immediately and vaccines are administered less than 2 weeks before starting eculizumab therapy, provide patients with 2 weeks of antibacterial drug prophylaxis. Baseline laboratory studies indicated; see Monitor.

Administer eculizumab at the recommended dosage regimen time points or within 2 days of these time points.

Paroxysmal nocturnal hemoglobinuria (PNH) in patients 18 years of age or older:

Administer 600 mg as an infusion weekly for the first 4 weeks, followed by 900 mg for the fifth dose 1 week later, then 900 mg every 2 weeks thereafter.

Atypical hemolytic uremic syndrome (aHUS) in patients 18 years of age or older:

Administer 900 mg as an infusion weekly for the first 4 weeks, followed by 1,200 mg for the fifth dose 1 week later, then 1,200 mg every 2 weeks thereafter.

Generalized myasthenia gravis in adults (gMG):

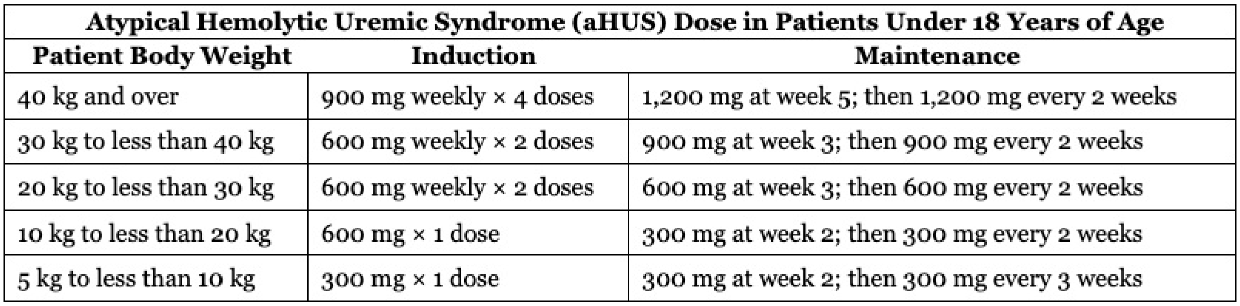
Administer 900 mg as an infusion weekly for the first 4 weeks, followed by 1,200 mg for the fifth dose 1 week later, then 1,200 mg every 2 weeks thereafter.

PEDIATRIC DOSE

See general comments under Usual Dose.

Atypical hemolytic uremic syndrome (aHUS) in patients under 18 years of age:

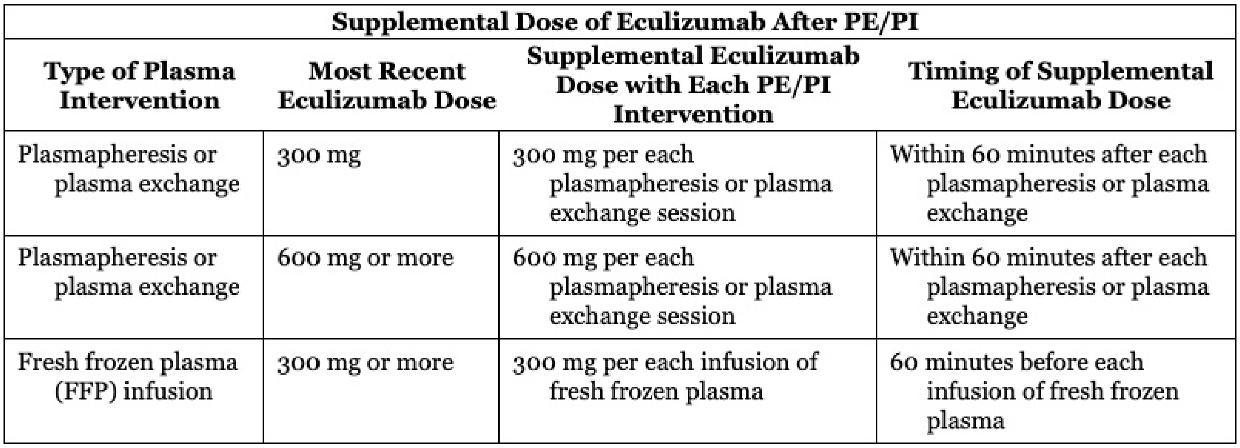
Administer eculizumab based on body weight as outlined in the following chart.



Atypical Hemolytic Uremic Syndrome (aHUS) Dose in Patients Under 18 Years of Age		
Patient Body Weight	**Induction**	**Maintenance**
40 kg and over	900 mg weekly × 4 doses	1,200 mg at week 5; then 1,200 mg every 2 weeks
30 kg to less than 40 kg	600 mg weekly × 2 doses	900 mg at week 3; then 900 mg every 2 weeks
20 kg to less than 30 kg	600 mg weekly × 2 doses	600 mg at week 3; then 600 mg every 2 weeks
10 kg to less than 20 kg	600 mg × 1 dose	300 mg at week 2; then 300 mg every 2 weeks
5 kg to less than 10 kg	300 mg × 1 dose	300 mg at week 2; then 300 mg every 3 weeks

DOSE ADJUSTMENTS

A variance of 1 to 2 days in the scheduled administration time points is allowed if indicated. ■ Age, gender, race, and renal function do not appear to influence the pharmacokinetics of eculizumab. ■ Supplemental dosing of eculizumab is required in patients with aHUS and adult patients with gMG in the setting of concomitant support with PE/PI (plasmapheresis or plasma exchange, or fresh frozen plasma infusion). See the following chart for supplemental dosing based on the type of intervention.



Supplemental Dose of Eculizumab After PE/PI			
Type of Plasma Intervention	**Most Recent Eculizumab Dose**	**Supplemental Eculizumab Dose with Each PE/PI Intervention**	**Timing of Supplemental Eculizumab Dose**
Plasmapheresis or plasma exchange	300 mg	300 mg per each plasmapheresis or plasma exchange session	Within 60 minutes after each plasmapheresis or plasma exchange
Plasmapheresis or plasma exchange	600 mg or more	600 mg per each plasmapheresis or plasma exchange session	Within 60 minutes after each plasmapheresis or plasma exchange
Fresh frozen plasma (FFP) infusion	300 mg or more	300 mg per each infusion of fresh frozen plasma	60 minutes before each infusion of fresh frozen plasma

DILUTION

Available in 300 mg/30 mL single-use vials (10 mg/mL). A clear, colorless solution. Withdraw the required dose of eculizumab (2 vials are required for the 600-mg dose, 3 vials are required for the 900-mg dose, and 4 vials are required for the 1,200-mg dose) and transfer it to an infusion bag. Must be further diluted to a 5 mg/mL concentration by adding an amount of NS, ½NS, D5W, or Ringer's injection to the infusion bag equal to the total volume of the eculizumab.

Preparation and Reconstitution of Eculizumab		
Eculizumab Dose	**Diluent Volume**	**Final Volume**
300 mg	30 mL	60 mL
600 mg	60 mL	120 mL
900 mg	90 mL	180 mL
1,200 mg	120 mL	240 mL

Invert gently to ensure thorough mixing. Allow the diluted solution to reach room temperature before infusion. Do not use an artificial heat source (e.g., microwave). Discard unused portions; contains no preservatives.

Filters:

Specific information not available.

Storage:

Refrigerate vials in original carton at 2° to 8° C (36° to 46° F) and protect from light. Vials may be held in the original carton at RT (not more than 25° C [77° F]) for only a single period up to 3 days. Do not use beyond the expiration date on the vial. Diluted solution is stable for 24 hours refrigerated or at RT. Do not freeze or shake.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not administer as an IV push or a bolus injection. For infusion via gravity feed, syringe-type pump, or infusion pump.

Adults:

A single dose as an infusion over 35 minutes. If infusion is slowed or stopped for any reason, the total infusion time should not exceed 2 hours.

Pediatric patients:

A single dose as an infusion over 1 to 4 hours.

ACTIONS

A recombinant, DNA-derived, humanized IgG monoclonal antibody. A genetic mutation in patients with paroxysmal nocturnal hemoglobinuria (PNH) leads to the generation of abnormal RBCs (known as PNH cells) that are deficient in terminal complement inhibitors; this deficiency makes these RBCs sensitive to persistent terminal complement-mediated destruction. Ongoing destruction of these RBCs is called hemolysis. Eculizumab, a complement inhibitor, specifically binds to the complement protein C5 and prevents complement-mediated intravascular hemolysis. It improves the lives of patients suffering from this disease by directly targeting the underlying disease process and markedly decreasing the ongoing RBC destruction that causes the hemolysis responsible for the S/S of PNH. In aHUS, impairment in the regulation of complement activity leads to uncontrolled terminal complement activation, resulting in platelet activation, endothelial cell damage, and thrombotic microangiopathy. Eculizumab inhibits the complement-mediated thrombotic microangiopathy (TMA) in patients with aHUS. Half-life is 270 to 375 hours. Plasma exchange or infusion increases clearance of eculizumab and reduces the half-life to 1.26 hours.

INDICATIONS AND USES

A complement inhibitor for the treatment of patients with paroxysmal nocturnal hemoglobinuria (PNH) to reduce hemolysis. PNH is a rare, disabling, and life-threatening genetic mutation blood disorder defined by chronic RBC destruction (hemolysis). Symptoms may include anemia; disabling fatigue; dysphagia; dyspnea; erectile dysfunction; hemoglobinuria; jaundice; recurrent pain in the abdomen, back, or head; renal dysfunction; and thromboses. Average age of onset is the early 30s. ■ Treatment of adult patients with generalized myasthenia gravis (gMG) who are anti–acetylcholine receptor (AchR) antibody-positive. ■ Treatment of patients with atypical hemolytic uremic syndrome (aHUS) to inhibit complement-mediated thrombotic microangiography; see Limitation of Use.

Limitation of use:

Eculizumab is NOT indicated for treatment of patients with Shiga toxin *E. coli*–related hemolytic uremic syndrome (STEC-HUS).

CONTRAINDICATIONS

Do not use in patients with unresolved serious *Neisseria meningitidis* infection or in patients not currently vaccinated against *N. meningitidis* unless the risk of delaying eculizumab therapy outweighs the risk of developing meningococcal infection.

PRECAUTIONS

For IV infusion only; do not administer by IV push or bolus injection.
■ Life-threatening and fatal meningococcal infections have occurred in patients treated with eculizumab. Susceptibility to serious meningococcal infections (septicemia and/or meningitis) is increased approximately 2,000-fold in comparison to the general U.S. population. Meningococcal infections may become rapidly life threatening or fatal if not recognized and treated early. ■ Comply with the most current Advisory Committee on Immunization Practices (ACIP) recommendations for meningococcal vaccination in patients with complement deficiencies. Revaccinate according to current medical guidelines, considering the duration of eculizumab therapy. ■ A meningococcal vaccine must be administered at least 2 weeks before initial dosing with eculizumab to all patients who have not been previously vaccinated unless the risks of delaying eculizumab therapy outweigh the risks of developing meningococcal infection. If urgent eculizumab therapy is indicated in an unvaccinated patient, administer the

meningococcal vaccine as soon as possible and provide patients with 2 weeks of antibacterial drug prophylaxis. In clinical studies, such patients received antibiotics for prophylaxis of meningococcal infection until at least 2 weeks after vaccination. Benefits and risks of antibiotic prophylaxis not established. Vaccination reduces, but does not eliminate, the risk of meningococcal infections. ■ Use caution in patients with any systemic infection. ■ Serious infections with *Neisseria species* (other than *N. meningitides*), including disseminated gonococcal infections, have been reported. Eculizumab blocks terminal complement activation; therefore patients may have increased susceptibility to infections, especially with encapsulated bacteria. *Aspergillus* infections have occurred in immunocompromised and neutropenic patients. Pediatric patients may be at increased risk of developing serious infections due to *Streptococcus pneumoniae* or *Haemophilus influenzae* type B (Hib). Administer vaccinations for prevention of these infections according to guidelines of the Advisory Committee on Immunization Practices (ACIP). ■ Serious hemolysis or thrombotic microangiopathy (TMA) may occur in patients who discontinue eculizumab therapy; see Monitor and Antidote. ■ A protein product; infusion reactions may occur. Hypersensitivity reactions, including anaphylaxis, are possible; however, infusion reactions severe enough to discontinue eculizumab did not occur during clinical trials. ■ Has a potential for immunogenicity. Low titers of antibodies to eculizumab have been detected but did not appear to correlate to clinical response. ■ Continue established anticoagulant therapy during eculizumab treatment; the effect of withdrawal of anticoagulant therapy during eculizumab therapy has not been established. ■ Eculizumab is available through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS). Prescribers must be enrolled in the program. Contact manufacturer for further information.

Monitor:

Obtain baseline and periodic CBC with differential and platelets, lactic dehydrogenase (LDH), SCr, bilirubin, and urinalysis. ■ LDH levels increase during hemolysis and with TMA. Monitoring may assist in determining the effectiveness of eculizumab therapy. ■ Monitor for early S/S of meningococcal infections (moderate to severe headache with nausea or vomiting, fever, or a stiff neck or stiff back; fever of 103° F [39.4° C] or higher; fever and a rash; confusion; and/or severe muscle aches with flu-like symptoms and light sensitivity). Evaluate immediately and treat with antibiotics if indicated. Discontinue eculizumab during treatment of serious meningococcal infections. ■ Monitor for other types of infections. ■ Monitor for S/S of an infusion or hypersensitivity reaction (e.g., chills, dyspnea, pruritus) during infusion and for at least 1 hour postinfusion. Slow or temporarily discontinue the infusion as indicated. ■ Monitor patients with PNH who discontinue eculizumab for a minimum of 8 weeks to detect serious hemolysis (S/S may include blood clots; chest pain; confusion; decreased hemoglobin, hematocrit, and haptoglobin; difficulty breathing; elevated LDH, bilirubin, or SCr; free serum hemoglobin; and hemoglobinuria with pink/red urine). ■ Monitor patients with aHUS who discontinue eculizumab for S/S of TMA complications for a minimum of 12 weeks. Clinical S/S of TMA may include angina, dyspnea, mental status changes, seizures, or thrombosis. Changes in laboratory parameters that may indicate TMA include a decrease in platelet count by 25% or more compared with baseline or nadir during eculizumab treatment or an increase in SCr and LDH by 25% or more compared with baseline or nadir during eculizumab treatment.

Patient Education:

Read the patient medication guide before initiating eculizumab and before each dose. ■ Meningococcal vaccination is required before initiating therapy. Previously vaccinated individuals may require a booster dose. Vaccination may not prevent meningococcal infection. Important to receive and stay up-to-date on all recommended immunizations. Discuss immunization status with physician. ■ Eculizumab affects the immune system and can lower the ability to fight infections. Immediately report S/S of a meningococcal infection (moderate to severe headache with nausea or vomiting, fever, or a stiff neck or stiff back; fever of 103° F [39.4° C] or higher; fever and a rash; confusion; and/or severe muscle aches with flu-like symptoms and light sensitivity). Manufacturer supplies a patient safety card that lists these symptoms. Card should be carried at all times during treatment and for 3 months after the last dose of eculizumab is administered. Share card with all health care providers treating you. ■ Promptly report other S/S of an infection. ■ Prevent gonorrheal infections; patients at risk should be tested regularly. ■ Promptly report chills, dyspnea, and/or itching during or soon after an infusion. ■ Report a suspected pregnancy and/or tell your doctor if you are breast-feeding. ■ Stopping the infusions may have serious side effects and requires prolonged monitoring for development of hemolysis or TMA. Increased risk of meningococcal infection continues for several weeks after eculizumab is discontinued.

Maternal/Child:

Use during pregnancy only if the benefits justify the potential risk to the fetus. There are risks to the mother and fetus associated with untreated PNH and aHUS. PNH in pregnancy is associated with adverse maternal outcomes, including bleeding, cytopenias (worsening), infections, miscarriages, thrombotic events, and increased maternal mortality, as well as adverse fetal outcomes, including fetal death and premature delivery. aHUS in pregnancy is associated with adverse maternal outcomes, including pre-eclampsia and preterm delivery, and adverse fetal/neonatal outcomes, including intrauterine growth restriction (IUGR), low birth weight and fetal death. Treatment with eculizumab may increase fetal survival and decrease maternal complications. ■ Use caution if breast-feeding; IgG is secreted in breast milk. There is insufficient information on the presence of eculizumab in human milk or the effects on breast-fed infants or human milk production. Consider risks to infant versus benefits of breast-feeding. ■ Safety and effectiveness have been established for use in pediatric patients for treatment of aHUS ■ Safety and effectiveness for use in pediatric patients have NOT been established for treatment of PNH or gMG. ■ Follow ACIP guidelines for vaccinations for prevention of infections due to *Neisseria meningitidis, Streptococcus pneumoniae,* and Hib.

Elderly:

Limited experience did not identify age-related differences in safety and effectiveness.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ **Intravenous immunoglobulin (IVIG)** treatment may interfere with the endosomal neonatal Fc receptor (FcRn) recycling mechanism of monoclonal antibodies, such as eculizumab, and decrease serum eculizumab concentrations. ■ Continue established anticoagulant therapy during eculizumab treatment; the effect of withdrawal of anticoagulant therapy during eculizumab therapy has not been established.

SIDE EFFECTS

PNH and aHUS:

Meningococcal infections (meningitis and/or septicemia) are the most serious side effects reported; may be life threatening and may occur in patients who have been vaccinated.

PNH:

The most commonly reported side effects are back pain, headache, nasopharyngitis, and nausea. The most serious reactions include anemia, fever, headache, infection (including viral infections), and the progression of PNH. Other reported side effects include constipation, cough, fatigue, herpes simplex infections, influenza-like illness, myalgia, pain in extremity, respiratory tract infection, and sinusitis.

aHUS:

The most commonly reported side effects are abdominal pain, anemia, cough, diarrhea, fever, headache, hypertension, nasopharyngitis, nausea, peripheral edema, upper respiratory infection, UTI, and vomiting. The most serious reactions include chronic renal failure, hypertension, infections, renal impairment, upper respiratory tract infection, and viral gastroenteritis. Other reported side effects include arthralgia, asthenia, back pain, bronchitis, fatigue, gastroenteritis, hypokalemia, hypotension, insomnia, leukopenia, neoplasms (benign, malignant, and unspecified), proteinuria, pruritus, rash, and renal impairment.

gMG:

The most commonly reported side effect is musculoskeletal pain. Other reported side effects include abdominal pain, arthralgia, fever, headache, diarrhea, infections, nasopharyngitis, nausea, peripheral edema, and upper respiratory tract infection.

Post-Marketing:

Cases of serious or fatal infections (e.g., *Neisseria gonorrhoeae, Neisseria meningitidis, Neisseria sicca/subflava, Neisseria* spp unspecified) have been reported.

ANTIDOTE

Keep physician informed of all side effects. Some will be treated symptomatically. Potential meningococcal infections must be evaluated immediately and treated with antibiotics promptly; may be life threatening. Treat hypersensitivity or infusion reactions as indicated; may respond to slowing or temporarily discontinuing the infusion or may require the use of epinephrine, corticosteroids, diphenhydramine bronchodilators (e.g., albuterol, aminophylline), IV saline, oxygen, and/or acetaminophen. Interrupt infusion and institute appropriate supportive measures if signs of cardiovascular instability or respiratory compromise occur. Total infusion time should not exceed 2 hours. If TMA complications occur after eculizumab is discontinued, consider reinstitution of treatment, plasma therapy (plasmapheresis, plasma exchange or FFP infusion [PE/PI]), or appropriate organ-specific supportive measures. Resuscitate as necessary.

EDARAVONE

(e-**DAR**-a-vone)
Radicava
Free radical scavenger
pH 4

USUAL DOSE

Initial treatment cycle:

60 mg as an IV infusion over 60 minutes once daily for 14 days, followed by a 14-day drug-free period.

Subsequent treatment cycles:

60 mg as an IV infusion over 60 minutes once daily for 10 days out of 14-day periods, followed by a 14-day drug-free period.

DOSE ADJUSTMENTS

The effect of renal or hepatic impairment on the pharmacokinetics of edaravone has not been studied. No dose adjustment is needed in patients with renal impairment or mild or moderate hepatic impairment. No specific dosing recommendations can be provided for patients with severe hepatic impairment. ■ Age, gender, and race have not been found to affect the pharmacokinetics of edaravone.

DILUTION

Available as a 60 mg/100 mL (0.6 mg/mL) clear, colorless, sterile solution in a single-dose polypropylene bag. Each bag is overwrapped with polyvinyl alcohol secondary packaging containing an oxygen absorber and oxygen indicator, which should be pink to reflect appropriate oxygen levels.

Filters:

Data are not available.

Storage:

Store at CRT. Protect from light. Store in overwrapped package to protect from oxygen degradation until time of use. The oxygen indicator will turn blue or purple if the oxygen has exceeded acceptable levels. Do not use if the oxygen indicator has turned blue or purple before opening the package. Once the overwrap package is opened, use within 24 hours.

COMPATIBILITY

Manufacturer states, “Other medications should not be injected into the infusion bag or mixed with edaravone.”

RATE OF ADMINISTRATION

A single dose equally distributed over 60 minutes.

ACTIONS

The mechanism by which edaravone exerts its therapeutic effect in patients with amyotrophic lateral sclerosis (ALS) is unknown. The maximum plasma concentration is reached by the end of the infusion. Edaravone is highly bound to plasma proteins, primarily albumin. It is metabolized to inactive sulfate and glucuronide conjugates and is excreted mainly in the urine as the glucuronide conjugate. Terminal elimination half-life is 4.5 to 6 hours.

INDICATIONS AND USES

Treatment of amyotrophic lateral sclerosis.

CONTRAINDICATIONS

History of hypersensitivity to edaravone or any of the inactive ingredients of this product.

PRECAUTIONS

For IV infusion only. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ Edaravone contains sodium bisulfite, a sulfite that may cause allergic-type reactions, including anaphylactic symptoms and life-threatening or less severe asthmatic episodes in susceptible people; use caution in patients with asthma.

Monitor:

Monitor for S/S of hypersensitivity reactions (e.g., dyspnea, erythema multiforme, hypotension, urticaria, wheals).

Patient Education:

Read FDA-approved patient information. ■ Promptly report S/S of a hypersensitivity reaction (e.g., breathing problems; dizziness; hives; itching; swelling of the face, lips, or tongue; wheezing). ■ Edaravone contains sodium bisulfite. ■ Notify health care provider if pregnant or breast-feeding or if you intend to become pregnant or breast-feed.

Maternal/Child:

There are no adequate data on the developmental risk associated with the use of edaravone in pregnant women. Adverse developmental effects (e.g., increased mortality, decreased growth, delayed sexual development, and altered behavior) have been observed in animal studies. ■ Use caution in breast-feeding. Data on the presence of edaravone in human milk and safety in breast-feeding are not available. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No overall differences in safety or effectiveness were observed between patients over 65 years of age and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

The pharmacokinetics of edaravone is not expected to be significantly affected by inhibitors of CYP enzymes, UGTs, or major transporters. ■ Edaravone and its metabolites are not expected to induce CYP1A2, CYP2B6, or CYP3A4.

SIDE EFFECTS

The most common adverse reactions are contusion, gait disturbance, and headache. Other commonly reported adverse reactions include dermatitis, eczema, glycosuria, hypoxia, respiratory failure, and tinea infection.

Post-Marketing:

Hypersensitivity reactions, including anaphylaxis.

ANTIDOTE

Discontinue the infusion at the first S/S consistent with a hypersensitivity reaction. Treat per standard of care (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids) and monitor until condition resolves. Resuscitate as necessary.

EDETATE CALCIUM DISODIUM BBW

(**ED**-eh-tayt **KAL**-see-um **DYE**-so-dee-um)
Calcium Disodium Edetate, Calcium Disodium Versenate, Calcium EDTA
Antidote
Chelating agent
Lead mobilization
pH 6.5 to 8

USUAL DOSE

Pretreatment:

Specific fluid requirements indicated; see Monitor and Maternal/Child.

Do not exceed recommended daily dose.

Asymptomatic adults and pediatric patients with blood lead levels over 20 mcg/dL but under 70 mcg/dL:

1,000 mg/M^2/24 hr (50 mg/kg/24 hr) for 3 to 5 days. After a rest period of 2 to 4 days (preferably up to 2 weeks) to allow for redistribution of lead, repeat the process, if indicated, based on severity of lead toxicity and patient tolerance.

Symptomatic adults and pediatric patients with blood levels over 70 mcg/dL:

Dimercaprol (BAL) will be given IM in divided doses every 4 hours for a minimum of 3 or up to 5 days. 4 hours after the first dose of BAL, begin edetate calcium disodium 1,000 mg/M^2/24 hr or 25 to 50 mg/kg/24 hr for 5 days. If blood lead concentrations rebound to above 45 mcg/dL within 5 to 7 days after the initial course, repeat the edetate calcium disodium. Do not repeat the dimercaprol regimen.

DOSE ADJUSTMENTS

Reduce dose in pre-existing renal disease and/or adults with lead nephropathy. In adults with lead nephropathy, dose is based on serum creatinine levels and repeated monthly until lead excretion is reduced toward normal according to the following chart.

Dose Adjustments in Impaired Renal Function and/or Adults With Lead Nephropathy

Serum Creatinine Level	Dose
<2 mg/dL	1,000 mg/M^2/24 hr for 5 days
2-3 mg/dL	500 mg/M^2/24 hr for 5 days
3-4 mg/dL	500 mg/M^2/48 hr for 3 doses
>4 mg/dL	500 mg/M^2/week

DILUTION

Add total daily dose to 250 to 500 mL of D5W or NS for infusion.

Storage:

Before use, store at CRT.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists amphotericin B (conventional), hydralazine, D10W, 10% invert sugar in NS, LR, Ringer’s solution, ⅙ M lactate as **incompatible.** Must be diluted in specific IV solutions; see Dilution.

RATE OF ADMINISTRATION

References vary greatly. Manufacturer recommends the total daily dose be evenly distributed over 8 to 12 hours. May cause an increase in intracranial pressure with too-rapid injection in patients with lead encephalopathy and cerebral edema.

ACTIONS

A chelating agent. Helps to remove metals, especially lead, from the body. Will form a stable chelate with metals that have the ability to displace calcium from the molecule (e.g., lead, zinc, cadmium). Distributed primarily in the extracellular fluid. Half-life is 20 to 60 minutes. Chelated compounds are excreted in urine; up to 50% in 1 hour and 95% in 24 hours. The primary source of lead chelated by edetate calcium disodium is from bone. Following administration, urinary lead output increases and blood lead concentration decreases, but brain lead is significantly increased due to internal redistribution of lead.

INDICATIONS AND USES

Reduction of blood levels and depot stores of lead in lead poisoning (acute and chronic) and lead encephalopathy in both pediatric and adult patients.

Unlabeled uses:

Treatment of poisoning by radioactive and nuclear fission products such as plutonium, thorium, uranium, and yttrium. ■ Treatment of poisoning from other heavy metals such as chromium, manganese, nickel, zinc, and possibly vanadium.

CONTRAINDICATIONS

Anuria, active renal disease, or hepatitis.

PRECAUTIONS

Do not confuse with edetate disodium, which does not chelate lead but actually removes calcium from the body and can be very dangerous. ■ Patients with lead encephalopathy and cerebral edema may have a lethal increase in intracranial pressure with IV infusion; IM injection preferred; see Maternal/Child. ■ Equally effective with IM or IV administration. IM route is used for all patients with overt lead encephalopathy and has been suggested as the preferred route by some for young pediatric patients. ■ Usually given IM in pediatric patients, unless given concurrently with BAL (insufficient IM injection sites); see Maternal/Child. ■ May produce toxic and fatal effects. ■ Produces the same renal damage as lead poisoning (e.g., proteinuria and microscopic hematuria). ■ Nephrotoxicity is dose dependent and may be reduced by ensuring adequate diuresis before treatment begins. ■ Use with caution in mild renal disease; see Dose Adjustments. ■ Patients must be removed from the source of contamination promptly. ■ Use for diagnosis of lead poisoning as a lead mobilization test is controversial; see literature. Edetate calcium disodium mobilization test should not be used in symptomatic patients or in patients with blood levels above 55 mcg/dL for whom appropriate therapy is indicated. ■ Not effective in mercury, gold, or arsenic poisoning.

Monitor:

Urine flow must be established before dimercaprol (BAL) or edetate calcium disodium is administered. IV fluids may be used. Avoid excessive fluid in patients with cerebral edema or lead encephalopathy. Once urine flow is established, further IV fluid is restricted in all patients to basal water and electrolyte requirements. ■ Monitor urinalysis, urine sediment, renal and hepatic function, and electrolyte levels before treatment; repeat daily in serious cases and on the second and fifth day in less serious cases. Daily urine specimens are recommended to determine status of renal function. ■ Monitor ECG and vital signs. ■ Elevated erythrocyte protoporphyrin levels (greater than 35 mcg/dL) indicate the need to perform a venous blood lead determination. ■ An elevation of urinary coproporphyrin (greater than 250 mcg/day in adults and greater than 75 mcg/day in pediatric patients under 80 lb) and an elevation of urinary delta-aminolevulinic acid (greater than 4 mg/day in adults and greater than 3 mg/M^2/day in pediatric patients) are associated with blood lead levels greater than 40 mcg/dL. ■ Excretion of calcium is not increased, but excretion of zinc and other essential metals is; monitor and replace as indicated. ■ Obtain specific fluid orders from the physician.

Patient Education:

If no urine output for 12 hours, report immediately.

Maternal/Child:

Category B: safety for use during pregnancy not established; benefits must outweigh risks. ■ Use caution in nursing mothers. ■ Lead poisoning is often more severe in pediatric patients compared with adult patients. Lead encephalopathy occurs more often in pediatric patients. May be incipient and thus overlooked. Mortality rate in pediatric patients has been high; see Precautions. ■ IV injection has been associated with fatality in some young children, and IM injection is considered to be the preferred route by some clinicians.

Elderly:

Consider age-related organ damage.

DRUG/LAB INTERACTIONS

Steroids will increase renal toxicity. ■ Inhibits the action of **zinc insulin** preparations by chelating the zinc.

SIDE EFFECTS

Acute renal tubular necrosis, anemia, anorexia, arthralgia, cardiac rhythm irregularities, chills, excessive thirst, fatigue, fever, headache, hematuria, hypercalcemia, hypersensitivity (e.g., sneezing, nasal congestion), hypotension, increases in liver function tests (mild), leg and other muscle cramps, malaise, myalgia, nausea, numbness, proteinuria, tetany, tingling, transient bone marrow suppression, tremors, vomiting, weakness, zinc deficiency.

ANTIDOTE

Notify the physician of any side effects. Most will improve with a decrease in rate of the infusion or will be treated symptomatically. Discontinue if urine flow stops to avoid high tissue levels of the drug. Discontinue at the first sign of renal toxicity (e.g., presence of large renal epithelial cells or increasing numbers of RBCs). Treat cerebral edema with repeated doses of mannitol. Not known if edetate calcium disodium is dialyzable.

EDETATE DISODIUM BBW

(**ED**-eh-tayt **DYE**-so-dee-um)
EDTA Disodium, Endrate
Antihypercalcemic agent
Calcium chelating agent
pH 6.5 to 7.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

50 mg/kg of body weight/24 hr or in equally divided doses every 12 hours (25 mg/kg every 12 hours). Total dose should not exceed 3 Gm/24 hr. Usually given for 5 days, held for 2 days. Regimen may be repeated to a total of 15 doses.

PEDIATRIC DOSE

40 mg/kg of body weight/24 hr in equally divided doses every 6 to 12 hours (20 mg/kg every 12 hours, 10 mg/kg every 6 hours). Do not exceed 70 mg/kg/24 hr or adult dose, whichever is less. See instructions in Usual Dose.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Recommended dose must be diluted in 500 mL D5W or NS and given as an infusion. A 0.5% solution will reduce the risk of thrombophlebitis. Do not exceed cardiac reserve in any patient. Use less diluent if necessary in pediatric patients. Must be diluted to at least a 3% solution.

Storage:

Store at room temperature.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Must not exceed more than 15 mg of actual medication over 1 minute. Total dose usually given over 3 to 4 hours. Rapid IV infusion may cause a sudden drop in serum calcium, resulting in tetany, convulsions, arrhythmias, and death. Reduce rate and further dilute solution for pain at injection site.

ACTIONS

A calcium-chelating agent. Also forms chelates with other polyvalent metals (e.g., magnesium, zinc). Attracts calcium ions immediately on injection and becomes calcium disodium edetate. Capable of severely depleting the body of calcium stores. Exerts a negative inotropic effect on the heart. It is well distributed in extracellular fluids and rapidly excreted in the urine.

INDICATIONS AND USES

Treatment of cardiac arrhythmias (atrial and ventricular, especially when caused by digoxin toxicity). ■ Hypercalcemia.

CONTRAINDICATIONS

Anuria, known sensitivity to edetate disodium, renal disease.

PRECAUTIONS

Read label carefully. Deaths have been caused when edetate disodium was administered mistakenly for edetate calcium disodium. ■ Used only when the severity of disease indicates necessity. ■ May produce hypocalcemia quickly, especially if used for purposes other than chelating calcium. ■ Use repeatedly with caution because of potential for nephrotoxicity and mobilization of extracirculatory calcium stores. ■ Use caution in cardiac disease (may adversely affect myocardial contractility), diabetes (lower blood sugar may require less insulin), severe renal disease, liver disease, congestive heart failure (1 Gm of sodium in each 5 Gm), limited cardiac reserve, and patients with a history of seizures or intracranial lesions.

Monitor:

Monitor vital signs and ECG before and during therapy. ■ Confirm patency of vein, avoid extravasation; can cause tissue necrosis. ■ Routine electrolyte panel (potassium deficiency) and urine specimens for casts and cells necessary during therapy. Magnesium, zinc, and other trace element deficiencies can occur. ■ Keep patient in supine position during and after administration (15 to 30 minutes) to avoid postural hypotension. ■ Obtain blood for serum calcium levels just before beginning a new infusion; specific lab methods required. ■ Inhibits coagulation of blood (transient). Liver function tests may be indicated. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy or breast-feeding not established. Use with extreme caution and only if clearly needed.

Elderly:

Reduced doses may be indicated; see Dose Adjustments. Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Inhibits **mannitol.** ■ Potentiates **neuromuscular blocking antibiotics** (e.g., gentamicin). ■ Inhibits coagulation of **blood** (transient). ■ A sudden drop in calcium levels may decrease effects of **digoxin.** ■ Obtain blood for **serum calcium levels** just before beginning a new infusion. Specific laboratory methods must be used for accurate evaluation.

SIDE EFFECTS

Anorexia, arthralgia, circumoral paresthesias, diarrhea, fatigue, fever, glycosuria, headache, hyperuricemia, hypotension, malaise, nasal congestion, nausea, numbness, sneezing, tearing, thirst, thrombophlebitis, urinary urgency, vomiting.

Major:

Anaphylaxis, anemia, cardiac arrhythmias, dermatitis, hemorrhage, hypocalcemic tetany, prolonged QT interval, renal tubular destruction (reversible), seizures, death.

ANTIDOTE

Notify the physician of any side effect. For progression of minor side effects or any major side effect, discontinue drug immediately and notify the physician. Calcium gluconate is the antidote of choice and should be available for infusion at all times (use extreme caution if patient is digitalized). Treat mild hypotension by maintaining in supine position until recovery. Additional hydration indicated with S/S of nephrotoxicity. Treat anaphylaxis and resuscitate as necessary.

EFGARTIGIMOD ALFA

(**EF**-gar-**TIG**-i-mod **AL**-fa)
Vyvgart
Neonatal Fc receptor antagonist

USUAL DOSE

10 mg/kg/dose every week for 4 weeks. Further infusions based on clinical response, but no sooner than 50 days from the start of the previous treatment cycle. Maximum dose 1.2 gm.

PEDIATRIC DOSE

No pediatric dosages provided by manufacturer.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

DILUTION

Dilute the required dose from each vial, which contains 400 mg in NS, to make 125 mL total volume. Gently invert bag; ***do not shake***.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS.

RATE OF ADMINISTRATION

Allow infusion to reach room temperature and infuse over 1 hour using a 0.22-micron filter. Flush entire line with NS.

ACTIONS

Efgartigimod afla is a human IgG1 antibody fragment that binds to the neonatal Fc receptor, resulting in a reduction of circulating IgG.

INDICATIONS AND USES

Myasthenia gravis.

CONTRAINDICATIONS

None given by manufacturer.

PRECAUTIONS

Ensure patient is up-to-date on vaccinations before starting therapy; live vaccines must be avoided during therapy. Infections may occur.

Monitor:

Monitor for S/S of infusion-related reactions (anaphylaxis, fever, chills, hypotension, rash, pruritus) throughout infusion and for 1 hour after infusion.

Patient Education:

Used for myasthenia gravis. May cause cold symptoms, headache, muscle pain. Contact physician with signs of infection (fever, chills), urinary tract infection, or a burning and numbness that is not normal.

Maternal/Child:

Other agents for myasthenia gravis are recommended if patient is pregnant or lactating.

Elderly:

Refer to Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

Bacille Calmette-Guérin (BCG) vaccine, baricitnib, brincidofovir, cladribine, COVID-19 vaccines (may decrease effectiveness), moderate and strong CYP3A4 inducers (may decrease effectiveness of efgartigimod; avoid), denosumab, Echinacea, fexinidazole, fingolimod, inebilizumab, influenza vaccines (may decrease effectiveness), leflunomide, natalizumab, ocrelizumab, ofatumumab, ozanimod, pidotimod, pimecrolimus (avoid), pneumococcal vaccine, polio vaccine (avoid), rabies vaccine, rubella or varicella live vaccines (avoid), ruxolitinib topical (avoid), sipuleucel-T, tacrolimus topical (avoid), talimogene laherparepvec (avoid), tertomotide (avoid), tofacitinib, typhoid vaccine (avoid), upadacitinib (avoid), live vaccines (avoid), varicella virus vaccine (avoid). Inactivated vaccines may have reduced response; give prior to therapy start. Please refer to package insert for further information.

SIDE EFFECTS

Angioedema; antibody development; cold symptoms; decreased neutrophils, WBC count; headache; hypersensitivity; lymphocytopenia; muscle pain; myalgia; paresthesia; respiratory tract infection.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

ELOSULFASE ALFA BBW

(**EL**-oh-**SUL**-fase **AL**-fa)
Vimizim
Enzyme replenisher
pH 5 to 5.8

USUAL DOSE

Premedication:

Treatment with antihistamines (e.g., diphenhydramine) with or without antipyretics (e.g., acetaminophen) 30 to 60 minutes before the start of the infusion is recommended.

Elosulfase alfa:

Adults and pediatric patients 5 years of age and older:

2 mg/kg once every week. Administer as an IV infusion over a minimum range of 3.5 to 4.5 hours, based on infusion volume; see Dilution.

DILUTION

Available as a concentrated solution for infusion (1 mg/mL) requiring dilution. One vial of 5 mL contains 5 mg. Determine the number of vials required using the following calculations:

Weight in kg × Dose/kg ÷ 5 mg/vial = # of vials required

For a 60-kg patient: [(60 kg)(2 mg/kg)] ÷ 5 mg/vial = 24 vials required. After patient is weighed and appropriate dose is calculated, remove sufficient vials from the refrigerator. Withdraw the calculated dose from the required number of vials. This calculated dose must be further diluted in NS to a final total volume of 100 mL for patients who weigh less than 25 kg and to a final total volume of 250 mL for patients who weigh 25 kg or more. Using the above example of a 120-mg dose, the calculated 120 mL would be further diluted with 130 mL of NS for a final total volume of 250 mL. Solution should be clear to slightly opalescent and colorless to pale yellow. A diluted solution with slight flocculation (e.g., thin translucent fibers) is acceptable for administration. Avoid agitation; gently rotate the bag to ensure proper distribution. ***Do not shake.***

Filters:

Use of a low–protein binding infusion set equipped with a low–protein binding, 0.2 micron in-line filter is required.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F). Protect from light. Do not freeze or shake. Immediate use after dilution is preferred; however, the diluted product may be refrigerated for up to 24 hours followed by up to 24 hours at 23° to 27° C (73° to 81° F). Administration should be completed within 48 hours of initial dilution. Do not freeze or shake. Protect from light. Discard any unused product.

COMPATIBILITY

Manufacturer states, “Do not infuse with other products in the infusion tubing. **Compatibility** with other products has not been evaluated.”

RATE OF ADMINISTRATION

Use of a low–protein binding infusion set equipped with a low–protein binding, 0.2 micron in-line filter is required. Use of an infusion pump is helpful. Flush the IV line with NS at the end of the infusion to ensure the total dose is received.

Weight less than 25 kg:

Begin with 3 mL/hr for the first 15 minutes. If tolerated, increase to 6 mL/hr for the next 15 minutes. If this rate is tolerated, then the rate may be increased every 15 minutes in 6 mL/hr increments, not to exceed 36 mL/hr. Total volume should be delivered over a minimum of 3.5 hours.

Weight 25 kg or more:

Begin with 6 mL/hr for the first 15 minutes. If tolerated, increase to 12 mL/hr for the next 15 minutes. If this rate is tolerated, then the rate may be increased every 15 minutes in 12 mL/hr increments, not to exceed 72 mL/hr. Total volume should be delivered over a minimum of 4.5 hours. The infusion may be slowed, temporarily stopped, or discontinued for that visit in the event of a hypersensitivity reaction.

ACTIONS

A formulation of elosulfase alfa, a purified human enzyme produced by recombinant DNA technology. A hydrolytic lysosomal glycosaminoglycan (GAG)–specific enzyme that hydrolyzes sulfate from either galactose-6-sulfate or N-acetyl-galactosamine-6-sulfate on the nonreducing ends of the glycosaminoglycans: keratin sulfate (KS) and chondroitin-6-sulfate (C6S). One of its chains binds a receptor at the cell surface, and the binding mediates cellular uptake of the protein to the lysosome. Mucopolysaccharidosis comprises a group of lysosomal storage disorders caused by the deficiency of specific lysosomal enzymes required for the catabolism of GAGs. Mucopolysaccharidosis type IVA (MPS IVA, or Morquio A syndrome) is characterized by the absence or marked reduction in N-acetylgalactosamine-6-sulfatase activity. This deficiency results in accumulation of the GAG substrates KS and C6S. This accumulation leads to widespread cellular, tissue, and organ dysfunction. Elosulfase alfa provides the exogenous enzyme N-acetylgalactosamine-6-sulfatase that will be taken up into the lysosomes and increase the catabolism of the GAGs KS and C6S. Elimination half-life was approximately 7.52 minutes at Week 0 and 35.9 minutes at Week 22. This change is likely related to the development of neutralizing antibodies.

INDICATIONS AND USES

Indicated for patients with mucopolysaccharidosis type IVA (MPS IVA; Morquio A syndrome).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Should be administered by or under the direction of a health care professional in facilities equipped to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have been reported and may occur at any time; see Monitor. ■ Patients with acute febrile or respiratory illness at the time of elosulfase alfa infusion may be at higher risk of life-threatening complications from hypersensitivity reactions. Carefully evaluate patient’s clinical status before administration and consider delaying the infusion. ■ Sleep apnea is common in MPS IVA patients. Evaluate airway patency before initiating treatment. Patients who use supplemental oxygen or continuous positive airway pressure (CPAP) during sleep should have these treatments readily available for use during the infusion in the event of an acute reaction or extreme drowsiness/sleep induced by antihistamine use. ■ Spinal or cervical cord compression (SCC) is a known and serious complication of MPS IVA and may occur at any time. ■ A protein substance, development of antidrug antibodies occurred in all patients in clinical trials. Because all patients developed antidrug antibodies, associations between antibody titers and decreased efficacy or an increase in the incidence of side effects (e.g., hypersensitivity) could not be determined.

Monitor:

Monitor closely for S/S of a hypersensitivity reaction (e.g., chest pain, cough, cyanosis, dyspnea, erythema, flushing, hypotension, rash, throat tightness, urticaria, and GI symptoms [e.g., abdominal pain, nausea and vomiting, retching]). Hypersensitivity reactions occurred as early as 30 minutes from the start of the infusion and from 3 hours up to 6 days after completion of the infusion. Anaphylaxis has occurred as late into treatment as the 47th infusion. ■ Obtain a baseline temperature and monitor for S/S of a respiratory infection. ■ Monitor for S/S of sleep apnea and initiate oxygen or CPAP as indicated. ■ Monitor for S/S of SCC (e.g., back pain, paralysis of limbs below the level of compression, urinary and fecal incontinence); give appropriate care as needed.

Patient Education:

Hypersensitivity reactions can occur at any time during and/or after the infusion. Promptly report S/S of a hypersensitivity reaction (e.g., chest pain, cough, cyanosis [bluish coloring around the lips], dyspnea [shortness of breath], erythema [redness of the skin], flushing, hypotension, rash, throat tightness, urticaria [hives], and GI symptoms [e.g., abdominal pain, nausea and vomiting, retching]). Seek immediate medical care if symptoms occur. ■ Report a respiratory infection before a treatment is to begin. ■ Inform health care professionals if you have sleep apnea and require oxygen or CPAP. ■ Use of effective contraception may be appropriate; consult your health care professional. ■ Participation in the Morquio A Registry is encouraged; contact BioMarin Pharmaceuticals.

Maternal/Child:

Category C: use during pregnancy only if potential benefits justify the potential risk to the fetus. Pregnancy can adversely affect the health of females affected with MPS IVA and lead to adverse pregnancy outcomes for both mother and fetus. There is a Morquio A Registry that collects data on pregnant women with MPS IVA who are treated with elosulfase alfa. ■ Use caution during breast-feeding. There is also a Morquio A Registry that collects data on breast-feeding women with MPS IVA who are treated with elosulfase alfa. ■ Safety and effectiveness has been established for use in pediatric patients 5 years of age and older.

Elderly:

Clinical studies did not include patients 65 years of age or older.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Abdominal pain, chills, fatigue, fever, headache, nausea, and vomiting are most common. Hypersensitivity reactions, including anaphylaxis, were the most serious side effects and may require discontinuation of therapy.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, slow the infusion rate or temporarily interrupt or discontinue the infusion. Manage acute reactions that require intervention by either temporarily interrupting or discontinuing the infusion and by administering additional antihistamines, antipyretics, or corticosteroids as necessary. Discontinue infusion immediately for anaphylaxis and treat with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Consider risk and benefits of readministering elosulfase alfa following a severe reaction. Patients with acute respiratory illness may be at risk for serious acute exacerbation of their respiratory compromise due to hypersensitivity reactions. Premedication and reduction of infusion rate may help to alleviate those reactions. Resuscitate as necessary.

ELOTUZUMAB

(**EL**-oh-**TOOZ**-ue-mab)
Empliciti
Monoclonal antibody
Antineoplastic

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor and Patient Education.

Premedication:

To reduce the risk of infusion reactions, premedicate with the following.

Dexamethasone:

Divide into an oral and an IV dose. Administer oral dose between 3 and 24 hours before elotuzumab infusion (see the following charts for specific dexamethasone dose based on regimen and age). Then 45 to 90 minutes before elotuzumab infusion, administer ***dexamethasone*** 8 mg IV, an ***H_1*** **blocker** (***diphenhydramine*** [25 to 50 mg orally or IV] or equivalent), an ***H_2*** **blocker** (***famotidine*** [20 mg IV or orally]), and ***acetaminophen*** (650 to 1,000 mg orally).

Elotuzumab in combination with lenalidomide and dexamethasone:

10 mg/kg as an infusion every week for the first 2 cycles (28-day cycle) and every 2 weeks thereafter in conjunction with the recommended dosing of lenalidomide and dexamethasone as described in the following chart. Continue treatment until disease progression or unacceptable toxicity. Refer to the prescribing information for dexamethasone and lenalidomide and other premedications as appropriate.

Recommended Dosing Schedule of Elotuzumab in Combination With Lenalidomide and Dexamethasone								
Cycle	**28-Day Cycles 1 and 2**				**28-Day Cycles 3+**			
Day of Cycle	**1**	**8**	**15**	**22**	**1**	**8**	**15**	**22**
Premedication[a]						—		—
Dexamethasone **(mg)** orally[b]	28 mg	28 mg	28 mg	28 mg	28 mg	40 mg	28 mg	40 mg
Dexamethasone **(mg)** IV[a]	8 mg	8 mg	8 mg	8 mg	8 mg	—	8 mg	—
Elotuzumab **(mg/kg)** IV	10 mg/kg	10 mg/kg	10 mg/kg	10 mg/kg	10 mg/kg	—	10 mg/kg	—
Lenalidomide **(mg)**	Days 1 to 21 (25 mg orally)				Days 1 to 21 (25 mg orally)			

[a] Premedicate 45 to 90 minutes before elotuzumab infusion with medications described under Premedication in Usual Dose (dexamethasone IV, an H1 blocker [diphenhydramine IV or PO or equivalent], an H2 blocker [famotidine (20 mg IV or orally)], and acetaminophen PO).

[b] Give 28 mg of dexamethasone orally between 3 and 24 hours before elotuzumab infusion and 40 mg of dexamethasone orally on days when elotuzumab is NOT administered.

Elotuzumab in combination with pomalidomide and dexamethasone:

10 mg/kg as an infusion every week for the first 2 cycles (28-day cycle). Starting at Cycle 3 (28-day cycle), administer elotuzumab 20 mg/kg IV every 4 weeks in conjunction with the recommended dosing of pomalidomide and dexamethasone as described in the following chart. Continue treatment until disease progression or unacceptable toxicity. Refer to the prescribing information for dexamethasone and pomalidomide and other premedications as appropriate.

Recommended Dosing Schedule of Elotuzumab in Combination With Pomalidomide and Dexamethasone								
Cycle	**28-Day Cycles 1 and 2**				**28-Day Cycles 3+**			
Day of Cycle	**1**	**8**	**15**	**22**	**1**	**8**	**15**	**22**
Premedication[a]						—	—	—
Dexamethasone **(mg)** orally[b] ≤75 years old	28 mg	28 mg	28 mg	28 mg	28 mg	40 mg	40 mg	40 mg
Dexamethasone **(mg)** orally[b] >75 years old	8 mg	8 mg	8 mg	8 mg	8 mg	20 mg	20 mg	20 mg
Dexamethasone **(mg)** IV[a]	8 mg	8 mg	8 mg	8 mg	8 mg	—	—	—
Elotuzumab **(mg/kg)** IV	10 mg/kg	10 mg/kg	10 mg/kg	10 mg/kg	20 mg/kg	—	—	—
Pomalidomide **(mg)**	Days 1 to 21 (4 mg orally)				Days 1 to 21 (4 mg orally)			

[a] Premedicate 45 to 90 minutes before elotuzumab infusion with medications described under Premedication in Usual Dose (dexamethasone IV, an H1 blocker [diphenhydramine IV or PO or equivalent], an H2 blocker [famotidine (20 mg IV or orally)], and acetaminophen PO).

[b] In addition dexamethasone is also administered orally. On days that elotuzumab is administered, administer oral dexamethasone between 3 and 24 hours before the elotuzumab infusion as follows: For patients 75 years or younger, give dexamethasone 28 mg orally. For patients older than 75 years, give dexamethasone 8 mg orally. On days that elotuzumab is not administered but a dose of dexamethasone is scheduled (Days 8, 15, and 22 of Cycle 3 and all subsequent cycles), give 40 mg orally to patients 75 years or younger and 20 mg orally to patients older than 75 years.

DOSE ADJUSTMENTS

If the dose of one drug in the regimen is delayed, interrupted, or discontinued, treatment with the other drugs may continue as scheduled. However, if dexamethasone is delayed or discontinued, base the decision regarding whether to administer elotuzumab on clinical judgment (i.e., risk of hypersensitivity). ■ Interrupt the elotuzumab infusion if a Grade 2 or higher infusion reaction occurs. Upon resolution to Grade 1 or lower, restart elotuzumab infusion at 0.5 mL/min and gradually increase at a rate of 0.5 mL/min every 30 minutes as tolerated to the rate at which the infusion reaction occurred. Resume the escalation regimen if there is no recurrence of the infusion reaction; see Rate of Administration and Antidote. ■ If the infusion reaction recurs, stop the elotuzumab infusion and do not restart on that day. ■ A severe infusion reaction may require permanent discontinuation of elotuzumab. ■ Dose delays and modifications for dexamethasone, pomalidomide, and lenalidomide should be performed as recommended in their Prescribing Information. ■ Clinically significant differences in the pharmacokinetics of elotuzumab were not observed based on age, sex, race, baseline LDH, albumin, renal impairment (including ESRD with or without dialysis), and mild hepatic impairment. Pharmacokinetics of elotuzumab in patients with moderate to severe hepatic impairment is unknown.

DILUTION

Available as a 300-mg or 400-mg single-dose vial. Calculate the dose (mg) based on patient weight, total volume (mL) of elotuzumab solution required, and the number of vials required using the following calculations:

$$(\text{Weight in kg} \times \text{dose/kg}) \div 300\ (400)\ \text{mg/vial} = \#\ \text{of vials required}$$

For a 60-kg patient: [(60 kg) × (10 mg/kg)] ÷ 300 (400) mg/vial = 2 vials of the 300-mg/vial solution or 1.5 vials of the 400-mg/vial solution. After patient is weighed and appropriate dose is calculated, remove sufficient vials from the refrigerator. Aseptic technique imperative. Using an 18-gauge or smaller needle, reconstitute the 300-mg vial with 13 mL of SWFI and the 400-mg vial with 17 mL SWFI to obtain a solution with a final concentration of 25 mg/mL. Some back pressure may be experienced and is normal. To dissolve the lyophilized cake, hold vial upright and swirl the solution by rotating the vial. Gently invert the vial a few times to dissolve all the powder. Avoid vigorous agitation. ***Do not shake;*** should dissolve in less than 10 minutes. Allow the reconstituted solution to stand for 5 to 10 minutes. Solution should be colorless to slightly yellow. Do not use if opaque particles, discoloration, or other foreign particles are present. Vials contain overfill. Withdraw the calculated dose and further dilute in NS or D5W to obtain a solution with a final concentration between 1 and 6 mg/mL. The volume of NS or D5W can be adjusted so as not to exceed 5 mL/kg of patient weight at any given dose of elotuzumab. Gently invert the infusion bag to mix the solution. Infusion bags must be made of polyvinylchloride (PVC) or polyolefin.

Filters:

Must be administered through an infusion set and a sterile, nonpyrogenic, low–protein binding filter (pore size 0.2 to 1.2 micrometers).

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light until time of use. Do not freeze or shake. The diluted product may be stored for up to 24 hours if refrigerated and protected from light (a maximum of 8 of the 24 hours can be at RT and room light). Bring to room temperature before infusion and use immediately. Infusion should be completed within 24 hours of reconstitution. Discard any unused product remaining in vials.

COMPATIBILITY

Manufacturer states, “Do not mix elotuzumab with, or administer as an infusion with, other medicinal products.” **Compatible** only with IV bags/containers made of polyvinylchloride (PVC) or polyolefin.

RATE OF ADMINISTRATION

For IV infusion only. Administer with an infusion set and a sterile, nonpyrogenic, low–protein binding filter (pore size 0.2 to 1.2 micrometers) using an infusion pump.

10 mg/kg dose:

Initiate the infusion rate at 0.5 mL/min. Increase in a stepwise fashion (see the following chart) if no infusion reactions develop.

Infusion Rate for Elotuzumab 10 mg/kg Dose				
Cycle 1, Dose 1		Cycle 1, Dose 2		Cycle 1, Doses 3 and 4 and All Subsequent Cycles
Time Interval	Rate	Time Interval	Rate	Rate
0–30 min	0.5 mL/min	0–30 min	3 mL/min	5 mL/min
30–60 min	1 mL/min	30 min or more	4 mL/min	
60 min or more	2 mL/min	—	—	

20 mg/kg dose:

Initiate the infusion rate at 3 mL/min. Increase in a stepwise fashion (see the following chart) if no infusion reactions develop. Patients who have escalated to 5 ml/min at the 10 mg/kg dose must decrease the rate to 3 mL/min at the first infusion at 20 mg/kg.

Infusion Rate for Elotuzumab 20 mg/kg Dose		
Dose 1		Dose 2 and All Subsequent Doses
Time Interval	Rate	Rate
0–30 min	3 mL/min	5 mL/min
30 min or more	4 mL/min	

10 or 20 mg/kg doses:

Interrupt elotuzumab for Grade 2 or higher infusion reactions and adjust the infusion rate; see Dose Adjustments. The maximum infusion rate should not exceed 5 mL/min.

ACTIONS

Elotuzumab is a humanized recombinant IgG1 monoclonal antibody that specifically targets the SLAMF7 (signaling lymphocytic activation molecule family member 7) protein. SLAMF7 is expressed on myeloma cells independent of cytogenetic abnormalities. It is also expressed on natural killer cells, plasma cells, and some specific immune cell subsets of differentiated cells within the hematopoietic lineage. Elotuzumab directly activates natural killer cells. It also targets SLAMF7 on myeloma cells and facilitates the interaction with natural killer cells to mediate the killing of myeloma cells through antibody-dependent cellular cytotoxicity (ADCC). In preclinical models, the combination of elotuzumab and lenalidomide resulted in enhanced activation of natural killer cells. Approximately 97% of the maximum steady-state concentration is predicted to be eliminated with a geometric mean (CV%) of 78 to 82.4 days.

INDICATIONS AND USES

Treatment of patients with multiple myeloma who have received one to three prior therapies. Used in combination with lenalidomide and dexamethasone. ■ Treatment of adult patients with multiple myeloma who have received at least two prior therapies, including lenalidomide and a proteasome inhibitor. Used in combination with pomalidomide and dexamethasone.

CONTRAINDICATIONS

Manufacturer states, “None.” Consider contraindications for lenalidomide and dexamethasone before starting therapy.

PRECAUTIONS

For IV infusion only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Can cause infusion reactions. Reports of infusion reactions during clinical trials were Grade 3 or lower, and most occurred during the first dose; see Monitor. ■ Infections, including opportunistic infections, have occurred; some resulted in discontinuation of therapy or fatalities. ■ Second primary malignancies, including hematologic malignancies, solid tumors, and skin cancers, have been reported. ■ Hepatotoxicity (elevations in liver enzymes [ALT, AST] greater than 3 times the ULN, total bilirubin greater than 2 times the ULN, and alkaline phosphatase less than 2 times the ULN) has been reported. ■ Can affect the determination of complete response and of disease progression in some patients with IgG kappa myeloma protein; see Drug/Lab Interactions. ■ A therapeutic protein; has the potential for immunogenicity.

Monitor:

Premedication required; see Usual Dose. ■ Obtain baseline CBC and differential and monitor as indicated during therapy. ■ Obtain baseline liver function tests (e.g., ALT, AST, bilirubin, and alkaline phosphatase) and monitor periodically. ■ Stop elotuzumab if Grade 3 or higher liver enzyme elevation occurs. Continuation of treatment may be considered after return to baseline values. ■ Monitor vital signs. ■ Monitor for S/S of infusion reactions; bradycardia, chills, fever, hypertension, and hypotension were most common. In patients who experience an infusion reaction, monitor vital signs every 30 minutes for 2 hours after the end of the elotuzumab infusion. ■ Immediately interrupt the infusion for infusion reactions of Grade 2 or higher; see Dose Adjustments and Antidote. ■ Monitor for S/S of infection. ■ Monitor for S/S of second primary malignancies.

Patient Education:

Review manufacturer’s medication guide. ■ Because of the combination use with lenalidomide or pomalidomide, pregnancy must be avoided. Effective contraception is required during treatment for men and women of reproductive potential. Consult with a health professional for specific information. ■ Premedication required to reduce the risk of infusion reactions. ■ Immediately report any S/S of infusion-related reactions (e.g., chills, difficulty breathing, fever, rash); may occur within 24 hours of an infusion. ■ Elotuzumab can affect the results of some tests, including testing for complete response, and additional testing may be indicated. ■ Promptly report S/S of infection (e.g., chills, cough, fever, pain with urination). ■ Second primary malignancies, including skin cancer, may occur; monitoring is required. Report unusual symptoms. ■ Report S/S of hepatotoxicity (abdominal pain, bruising, fatigue, itching, jaundice).

Maternal/Child:

Combination drug regimen can cause fetal harm; avoid pregnancy; see Patient Education. ■ Discontinue breast-feeding. Combination drug regimen may have serious effects in a breast-feeding infant. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or efficacy have been reported between elderly patients and younger adults receiving elotuzumab in combination with lenalidomide and dexamethasone. Studies with elotuzumab in combination with pomalidomide and dexamethasone did not include sufficient numbers of patients age 65 years and over to determine whether they respond differently than younger patients.

DRUG/LAB INTERACTIONS

For important drug interactions involving lenalidomide, pomalidomide, and dexamethasone, refer to their respective prescribing information. ■ Elotuzumab may be detected on both the serum protein electrophoreses (SPEP) and immunofixation (IFE) assays used for the clinical monitoring of endogenous M protein and can interfere with correct response classification. This interference can affect the determination of complete response and possibly relapse from complete response in patients with IgG kappa myeloma protein.

SIDE EFFECTS

The most frequently reported side effects when administered in combination with lenalidomide and dexamethasone include constipation, cough, decreased appetite, diarrhea, fatigue, fever, nasopharyngitis, peripheral neuropathy, pneumonia, and upper respiratory tract infections. The most frequently reported side effects when administered in combination with pomalidomide and dexamethasone are constipation and hyperglycemia. Acute renal failure, altered mood, anemia, bone pain, bradycardia, cataracts, chest pain, dyspnea, edema (peripheral), headache, hepatotoxicity, hypersensitivity/infusion reactions, hypertension, hypoesthesia, hyponatremia, hypotension, infections, muscle spasms, night sweats, oropharyngeal pain, pain in extremities, pulmonary embolism, second primary malignancies, tachycardia, weight loss, and vomiting have also been reported. Reported laboratory abnormalities included elevated alkaline phosphatase, hyperglycemia, hyperkalemia, hypoalbuminemia, hypocalcemia, leukopenia, lymphopenia, low bicarbonate, and thrombocytopenia.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. If a Grade 2 or higher infusion reaction occurs, interrupt elotuzumab infusion and institute appropriate medical and supportive measures. Severe infusion reactions may require permanent discontinuation of elotuzumab therapy. Stop elotuzumab upon Grade 3 or higher elevation of liver enzymes. After return to baseline values, continuation of therapy may be considered. Discontinue administration at the first sign of a serious hypersensitivity reaction and treat as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary. Does not appear to be removed by dialysis.

EMAPALUMAB-lzsg

(**EM**-a-**PAL**-ue-mab)
Gamifant
Monoclonal Antibody

USUAL DOSE

Pretreatment:

Pretesting required and baseline studies indicated; see Monitor.

Premedications:

Administer prophylaxis for herpes zoster, *Pneumocystis jirovecii,* and for fungal infections before emapalumab-lzsg administration.

Concomitant medications:

For patients who are not already receiving baseline dexamethasone treatment, begin dexamethasone at a daily dose of at least 5 to 10 mg/M^2 the day before emapalumab-lzsg treatment begins. Patients who are already receiving baseline dexamethasone may continue their regular dexamethasone dose provided that the dose is at least 5 mg/M^2. Dexamethasone can be tapered according to the judgment of the treating physician.

Emapalumab-lzsg:

The recommended starting dose is 1 mg/kg as an IV infusion over 1 hour twice per week (every 3 to 4 days). Subsequent doses may be increased based on clinical and laboratory criteria; see Dose Adjustments. Administer emapalumab-lzsg until hematopoietic stem cell transplantation (HSCT) is performed or there is unacceptable toxicity. Discontinue emapalumab-lzsg when the patient no longer requires therapy for the treatment of hemophagocytic lymphohistiocytosis (HLH).

DOSE ADJUSTMENTS

Titrate the dose upward as outlined in the following chart if disease response is unsatisfactory. After the patient’s clinical condition is stabilized, decrease the dose to the previous level to maintain clinical response.

Emapalumab-lzsg Dose Titration Criteria		
Treatment Day	**Emapalumab-lzsg Dose**	**Criteria for Dose Increase**
Day 1	Starting dose of 1 mg/kg	N/A
On Day 3	Increase to 3 mg/kg	Unsatisfactory improvement in clinical condition as assessed by a health care provider AND at least one of the following: • Fever: persistence or recurrence • Platelet count If baseline <50,000/mm^3 and no improvement to >50,000/mm^3 If baseline >50,000/mm^3 and <30% improvement If baseline >100,000/mm^3 and decrease to <100,000/mm^3 • Neutrophil count If baseline <500/mm^3 and no improvement to >500/mm^3 If baseline 500-1,000/mm^3 and decrease to <500/mm^3 If baseline 1,000-1,500/mm^3 and decrease to <1,000/mm^3 • Ferritin (ng/mL) If baseline ≥3,000 ng/mL and <20% decrease If baseline <3,000 ng/mL and any increase to >3,000 ng/mL • Splenomegaly: any worsening • Coagulopathy (both d-dimer and fibrinogen must apply) D-dimer: if abnormal at baseline and no improvement Fibrinogen (mg/mL) If baseline levels ≤100 mg/dL and no improvement If baseline levels >100 mg/dL and any decrease to <100 mg/dL
From Day 6 onward	Increase to 6 mg/kg	
From Day 9 onward	Increase to 10 mg/kg	Assessment by a health care provider that, based on initial signs of response, a further increase in emapalumab-lzsg dose can be of benefit

No clinically significant differences in the pharmacokinetics of emapalumab-lzsg were observed based on age, sex, race, renal impairment (including dialysis), or hepatic impairment (mild, moderate, and severe).

DILUTION

Available in 10 mg/2 mL and 50 mg/10 mL (5 mg/mL) single-dose vials. Solution is clear to slightly opalescent, colorless to slightly yellow. Calculate the dose (mg/kg) of emapalumab-lzsg, the total volume (mL) required, and the number of vials needed based on patient actual body weight. Withdraw the necessary volume of solution and dilute with NS to a maximum concentration of 2.5 mg/mL. Do not dilute product to less than 0.25 mg/mL. The diluted solution can be placed in either a syringe or an infusion bag depending on the volume needed. Use a gamma-irradiated, latex-free, polyvinyl chloride (PVC)-free syringe or a non-PVC polyolefin infusion bag. Do not use with ethylene oxide–sterilized syringes.

Filters:

Administer through an IV line containing a sterile, nonpyrogenic, low–protein-binding, 0.2-micron in-line filter.

Storage:

Store emapalumab-lzsg in a refrigerator at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake. If not administered immediately, store the diluted solution under refrigeration at 2° to 8° C (36° to 46° F) for no more than 4 hours from the time of dilution. Allow refrigerated solution to come to room temperature before administration. Do not freeze. Do not shake. Discard any unused solution contained in the vial or diluted for infusion.

COMPATIBILITY

Manufacturer states, "Do not infuse emapalumab-lzsg concomitantly with other agents and do not add any other product to the infusion bag or syringe." Use a gamma-irradiated, latex-free, polyvinyl chloride (PVC)-free syringe or a non-PVC polyolefin infusion bag. Do not use with ethylene oxide–sterilized syringes.

RATE OF ADMINISTRATION

A single dose administered as an IV infusion over 1 hour. Administer through an IV line containing a sterile, nonpyrogenic, low–protein-binding, 0.2-micron in-line filter. In the event of an infusion-related reaction, the infusion may be interrupted and re-initiated at a slower rate.

ACTIONS

Emapalumab-lzsg is an interferon gamma (IFNγ) blocking antibody produced by recombinant DNA technology that binds to and neutralizes IFNγ. Nonclinical data suggest that IFNγ plays a pivotal role in the pathogenesis of HLH by being hypersecreted. Emapalumab-lzsg exhibits target-mediated clearance dependent on INFγ production, which can vary between and within patients as a function of time and can affect the recommended dosage. Half-life is approximately 22 days in healthy subjects and ranged from 2.5 to 18.9 days in HLH patients. The metabolic pathway of emapalumab-lzsg has not been characterized. As with other proteins, it is expected to be degraded into small peptides and amino acids via catabolic pathways.

INDICATIONS AND USES

Treatment of adult and pediatric (newborn and older) patients with primary hemophagocytic lymphohistiocytosis (HLH) with refractory, recurrent, or progressive disease or intolerance with conventional HLH therapy.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

May increase the risk of fatal and serious infections to include specific pathogens favored by IFNγ neutralization, including mycobacteria, herpes zoster virus, and *Histoplasma capsulatum*. Do not administer emapalumab-lzsg in patients with infections caused by these pathogens until appropriate treatment has been initiated. ■

Serious infections, including sepsis, bacteremia, pneumonia, disseminated histoplasmosis, necrotizing fasciitis viral infections, and perforated appendicitis have been reported. Reported pathogens were bacterial, viral, fungal, and of unknown origin. ■ Infusion-related reactions have been reported and were rated as mild to moderate in severity. ■ As with all therapeutic proteins, there is the chance for immunogenicity. ■ See Drug/Lab Interactions.

Monitor:

Test for latent tuberculosis infections using the purified protein derivative (PPD) or IFNγ release assay. ■ Evaluate patients for tuberculosis risk factors before initiating therapy. Administer tuberculosis prophylaxis to patients at risk for tuberculosis or known to have a positive PPD test result or positive IFNγ release assay. ■ Obtain baseline and periodic neutrophil count, platelet count, ferritin, D-dimer, and fibrinogen to help guide therapy; see Dose Adjustments. ■ Monitor for persistent or recurrent fever. ■ Monitor for tuberculosis, adenovirus, EBV, and CMV every 2 weeks and as clinically indicated. ■ Closely monitor for other S/S of infection. Initiate a complete diagnostic workup appropriate for an immunocompromised patient and initiate antimicrobial therapy as indicated. ■ Monitor for S/S of an infusion related reaction (e.g., drug eruption, erythema, fever, hyperhidrosis, rash). One-third of reported reactions occurred during the first infusion.

Patient Education:

Read the FDA-approved patient medication guide. ■ Report S/S of infection. ■ Review vaccination status with provider; see Drug/Lab Interactions. ■ Report S/S of infusion-related reactions.

Maternal/Child:

Information on use in pregnancy and breast-feeding is not available. Use with caution and evaluate risk versus benefit. ■ Safety and effectiveness have been established in pediatric patients, newborn and older, with primary HLH that is reactivated or refractory to conventional therapies.

Elderly:

Clinical studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently from younger patients. Differences have not been identified.

DRUG/LAB INTERACTIONS

Do not administer live or live-attenuated vaccines to patients receiving emapalumab-lzsg and for at least 4 weeks after the last dose of emapalumab-lzsg. Safety of immunization with live vaccines during or after therapy has not been studied. ■ The formation of CYP450 enzymes may be suppressed by increased levels of cytokines such as IFNγ. By neutralizing IFNg, emapalumab-lzsg may normalize CYP450 activities, which may reduce the efficacy of drugs that are **CYP450 substrates** due to increased metabolism. Monitor for reduced efficacy and adjust dosage of CYP450 substrate drugs as appropriate when emapalumab-lzsg therapy is initiated or discontinued.

SIDE EFFECTS

The most commonly reported adverse reactions were fever, hypertension, infections, and infusion-related reactions. The most commonly reported serious reactions were GI hemorrhage, infections, and multiple organ dysfunction. Other adverse reactions included abdominal pain, constipation, cough, cytomegalovirus infection, diarrhea, hypokalemia, irritability, lymphocytosis, rash, tachycardia, and tachypnea. Other reactions were reported in fewer than 10% of study patients.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Interrupt the infusion for an infusion-related reaction and institute appropriate medical management before continuing the infusion at a slower rate.

ENALAPRILAT BBW

(en-**AL**-ah-prill-at)
ACE inhibitor
Antihypertensive
Vasodilator
pH 6.5 to 7.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

Enalaprilat:

1.25 mg every 6 hours. Doses up to 5 mg every 6 hours have been tolerated for up to 36 hours, but clinical studies have not shown a need for dosage over 1.25 mg. Dosage is the same (1.25 mg) when converting from oral to IV therapy. Resume oral therapy as soon as tolerated. See Precautions.

PEDIATRIC DOSE (UNLABELED)

Infants and pediatric patients:

5 to 10 mcg/kg/dose every 8 to 24 hours, not to exceed 1.25 mg/dose. Dose and frequency determined by clinical response.

Adolescents:

0.625 to 1.25 mg every 6 hours. See Maternal/Child.

DOSE ADJUSTMENTS

Reduce initial dose to 0.625 mg in patients taking diuretics, patients with CHF, hyponatremia, severe volume or salt depletion, a CrCl less than 30 mL/min, and dialysis patients; see Rate of Administration. If the 0.625 dose is not clinically effective after 1 hour, it may be repeated. Additional doses of 1.25 mg may be administered at 6-hour intervals. ■ Blood levels may be increased in the elderly; dose selection should be cautious. Consider decreased cardiac, hepatic, and renal function; concomitant disease; or other drug therapy. ■ See Drug/Lab Interactions and Precautions.

DILUTION

May be given undiluted through the port of a free-flowing infusion of NS, D5W, D5NS, D5LR, or Isolyte E. May also be diluted in up to 50 mL of any of the same solutions and given as an infusion.

Storage:

Store at CRT. Stable for up to 24 hours after dilution.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be evenly distributed over 5 minutes. Extend rate of infusion up to 1 hour in patients at risk for severe hypotension (e.g., heart failure, hyponatremia, high-dose diuretic therapy, recent intensive diuresis or increase in diuretic dose, renal dialysis, or severe volume and/or salt depletion of any etiology).

ACTIONS

An antihypertensive agent. The active metabolite of the orally administered prodrug enalapril maleate. An angiotensin-converting enzyme (ACE) inhibitor that prevents conversion of angiotensin I to the vasoconstrictor substance angiotensin II. Angiotensin II also stimulates aldosterone secretion by the adrenal cortex. Inhibition of ACE results in decreased plasma angiotensin II, which leads to decreased vasopressor activity and decreased aldosterone secretion. A decrease in aldosterone secretion results in a small increase of serum potassium. Administration of enalaprilat results in a decrease of both supine and standing systolic and diastolic BP, usually with no orthostatic component. Onset of action is usually within 15 minutes. Peak BP reduction occurs in 1 to 4 hours, and effects last up to 6 hours. Peak effects after the first dose may not occur for up to 4 hours after administration. Peak effects of subsequent doses may be greater than the initial dose. Excreted in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of hypertension when oral therapy is not practical.

Unlabeled uses:

Treatment of pediatric hypertensive urgency or emergency.

CONTRAINDICATIONS

Hypersensitivity to enalaprilat or its components. ■ A history of angioedema related to previous treatment with an ACE inhibitor, or hereditary or idiopathic angioedema. ■ Coadministration of aliskiren with enalaprilat in patients with diabetes. ■ Administration in combination with a neprilysin inhibitor (e.g., sacubitril/valsartan); see Drug/Lab Interactions.

PRECAUTIONS

Excessive hypotension is rare in uncomplicated hypertensive patients but may occur in patients who are severely salt/volume depleted. Patients at risk for excessive hypotension include those with the following conditions or characteristics: heart failure, hyponatremia, high-dose diuretic therapy, recent intensive diuresis or increase in diuretic dose, renal dialysis, or severe volume and/or salt depletion of any etiology. Excessive hypotension may be associated with oliguria and/or progressive azotemia and, rarely, with acute renal failure and/or death. In patients at risk, consider discontinuing the diuretic, decreasing the diuretic dose, or increasing salt intake cautiously, if possible, before initiating enalaprilat therapy. ■ Use caution in patients with ischemic heart or cerebrovascular disease; an excessive fall in blood pressure could result in MI or stroke. ■ Angioedema of the face, extremities, lips, tongue, glottis, and/or larynx has been reported and may occur at any time during treatment. Angioedema associated with laryngeal edema may be fatal. See Drug/Lab Interactions. ■ Intestinal angioedema has been reported. Patients may present with abdominal pain, with or without nausea and vomiting. ■ Use caution in patients with aortic stenosis or hypertrophic cardiomyopathy. ■ Use caution in patients with collagen vascular disease and renal disease; neutropenia and/or agranulocytosis have been reported with captopril, another ACE inhibitor. Monitoring of WBC may be indicated. ■ Use caution in surgery, with anesthesia, or with agents that produce hypotension. ■ May rarely cause a syndrome that starts with cholestatic jaundice, progresses to hepatic necrosis, and may progress to death. Discontinue in patients who develop elevated liver enzymes or jaundice. ■ May cause oliguria or progressive azotemia in patients with severe congestive heart failure whose renal function is dependent on the activity of the renin-angiotensin-aldosterone system. Acute renal failure and death are possible. ■ Increases in BUN and SCr have been observed and are more likely to occur in patients with pre-existing renal impairment. Dose reduction and/or discontinuation of diuretic therapy may be required. ■ ACE inhibitors often cause a persistent, nonproductive cough, which should resolve when drug is discontinued. ■ In clinical trials, ACE inhibitors had less of an effect on blood pressure in Black patients compared with non-Black patients. In addition, Black patients have been reported to have a higher incidence of angioedema compared with non-Black patients. ■ Has been used intravenously for up to 7 days. ■ Average dose for conversion to oral therapy is 5 mg/day as a single dose. When a reduced dose of enalaprilat IV has been indicated (e.g., diuretics, impaired renal function [CrCl ≤30 mL/min], dialysis), reduce initial oral dose to 2.5 mg/day as a single daily dose. Adjust dose based on BP response. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Monitor vital signs frequently. May cause excessive drop in BP following the first dose. ■ Use extreme caution in patients with volume and/or salt depletion. ■ Monitor BUN and SCr. ■ Monitor serum potassium levels; may cause hyperkalemia. May cause a significant increase in serum potassium with concurrent use of potassium-sparing diuretics or potassium supplements. Use with caution and only for documented hypokalemia. Use salt substitutes with caution. ■ Monitor for S/S of angioedema. Intestinal angioedema has been diagnosed by abdominal CT scan or ultrasound or during surgery. ■ Monitoring of WBC may be indicated in patients with collagen vascular disease or renal disease. ■ See Drug/Lab Interactions.

Patient Education:

Consider birth control options. ■ May cause dizziness; avoid sudden changes in posture and request assistance for ambulation if necessary. Promptly report S/S of any adverse reaction (e.g., difficulty breathing, rash, swelling of face, tongue, or other body parts).

Maternal/Child:

Category D. Drugs that act directly on the renin-angiotensin system can cause injury and death to the developing fetus. These adverse outcomes are usually associated with use in the second and third trimester of pregnancy. When pregnancy is detected, discontinue enalaprilat as soon as possible; see prescribing information for further information. ■ Observe any infant with in utero exposure for hypotension and oliguria. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established but has been used. ■ May contain benzyl alcohol, which has been associated with a fatal “gasping syndrome” in neonates.

Elderly:

Dose selection should be cautious; see Dose Adjustments and Precautions/Monitor.

DRUG/LAB INTERACTIONS

Use caution in surgery, with **anesthesia,** or with any **agents that produce hypotension.** ■ Dual blockade of the renin-angiotensin system (RAS) with **angiotensin receptor blockers, ACE inhibitors,** or **aliskiren** is associated with increased risks of hypotension, hyperkalemia, and changes in renal function (including acute renal failure) compared with monotherapy. In general, combined use of **RAS inhibitors** should be avoided. ■ Has been used with other cardiovascular agents, including digitalis, beta-adrenergic–blocking agents, methyldopa, nitrates, calcium-blocking agents, hydralazine, and prazosin, without evidence of clinically significant adverse interactions. ■ **Diuretics** given concomitantly may cause an excessive drop in BP, especially in at-risk patients. ■ **Antihypertensive agents that cause renin release** (e.g., diuretics) potentiate the antihypertensive effect of enalaprilat. ■ May cause hyperkalemia with **potassium-sparing diuretics, potassium supplements**, or **potassium-containing salt substitutes**. ■ In patients who are elderly, volume depleted (including those receiving diuretic therapy), or have compromised renal function, concurrent use with **NSAIDs** may result in further deterioration of renal function, including acute renal failure. ■ Concurrent use with **NSAIDs** may also decrease the hypotensive effects of enalaprilat by inhibiting the renal prostaglandin synthesis and/or by causing sodium and fluid retention. ■ May increase **lithium** concentration, resulting in lithium toxicity. ■ Nitritoid reactions (symptoms include facial flushing, nausea, vomiting, and hypotension) have been reported rarely in patients receiving therapy with **injectable gold** (sodium aurothiomalate) and concomitant ACE inhibitor therapy. ■ Coadministration of an ACE inhibitor and an **mTOR inhibitor** (e.g., temsirolimus, sirolimus, everolimus) may increase the risk for angioedema. ■ Patients taking a concomitant **neprilysin inhibitor** (e.g., sacubitril/valsartan) may be at increased risk for angioedema. Do not administer enalaprilat within 36 hours of switching to or from sacubitril/valsartan. ■ Concomitant use with **aliskiren** is contraindicated in patients with diabetes and should be avoided in all patients with GFR <60 mL/min. ■ See Precautions and Monitor.

SIDE EFFECTS

Hypotension was the most frequently reported adverse event, followed by headache and nausea. Other reported adverse reactions include abdominal pain, alopecia, angina, angioedema, anorexia, anosmia (absence of sense of smell), asthenia, asthma, ataxia, atrial fibrillation, blurred vision, bone marrow suppression, bradycardia, bronchitis, bronchospasm, cardiac arrest, cerebrovascular accident, chest pain, confusion, conjunctivitis, constipation, cough (persistent, dry), decreases in hemoglobin and hematocrit, depression, diaphoresis, diarrhea, dizziness, dream abnormality, dry eyes, dry mouth, dyspepsia, dyspnea, elevated LFTs, eosinophilic pneumonitis, erythema multiforme, exfoliative dermatitis, fatigue, fever, flank pain, flushing, glossitis, gynecomastia, hepatotoxicity, herpes zoster, hoarseness, hyperkalemia, hyponatremia, hypotension (severe), ileus, impotence, increased SCr and BUN, insomnia, melena, MI, muscle cramps, nervousness, neutropenia, oliguria, palpitations, pancreatitis, pemphigus, peripheral neuropathy, photosensitivity, pneumonia, pruritus, pulmonary edema, pulmonary embolism and infarction, pulmonary infiltrates, rash, Raynaud's phenomenon, renal dysfunction, renal failure (reversible), rhinorrhea, somnolence, sore throat, Stevens-Johnson syndrome, stomatitis, syncope, taste disturbances, tearing, thrombocytopenia, toxic epidermal necrolysis, upper respiratory infection, urinary tract infection, urticaria, vertigo, vomiting. Anaphylaxis has been reported.

ANTIDOTE

For minor side effects, notify the physician. Most will be tolerated or treated symptomatically. If symptoms progress or any major side effect occurs (angioedema, excessive hypotension), discontinue drug and notify the physician immediately. If hypotension occurs, place the patient in the supine position and, if necessary, administer an IV infusion of NS. Other drugs in the regimen (e.g., diuretics) may need to be discontinued or the dosage reduced. Epinephrine, diphenhydramine, and hydrocortisone may be used to treat angioedema. Maintain the patient as indicated. If cardiac arrhythmias occur, treat appropriately. Hemodialysis may be useful in toxicity.

ENFORTUMAB VEDOTIN-ejfv

(en-**FORT**-ue-mab ve-**DOE**-tin)
Padcev

Antineoplastic
(Anti-nectin-4 antibody-drug conjugate [ADC])
pH 6

USUAL DOSE

Pretreatment:

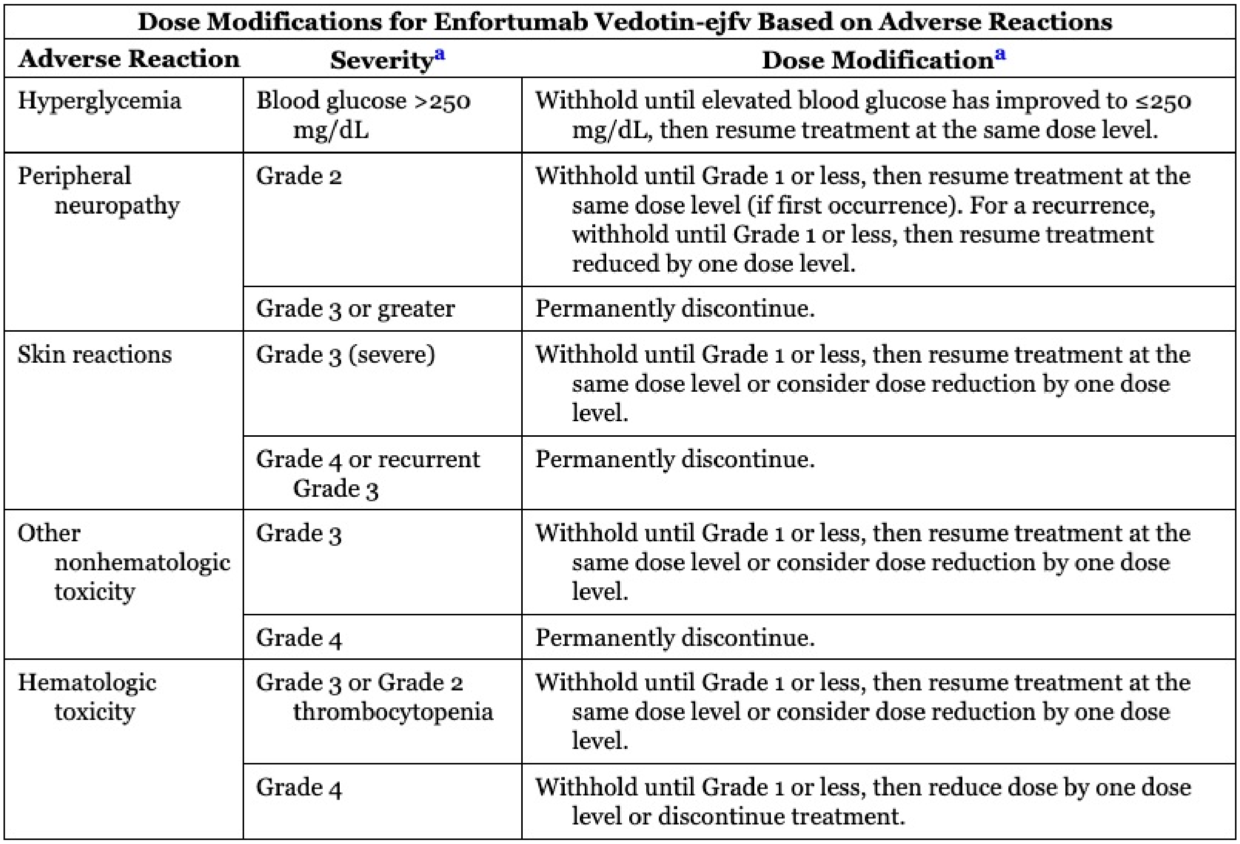
Verify pregnancy status; see Patient Education.

Enfortumab vedotin-ejfv:

1.25 mg/kg (up to a maximum of 125 mg for patients 100 kg or greater). Administered as an IV infusion over 30 minutes on Days 1, 8, and 15 of a 28-day cycle until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

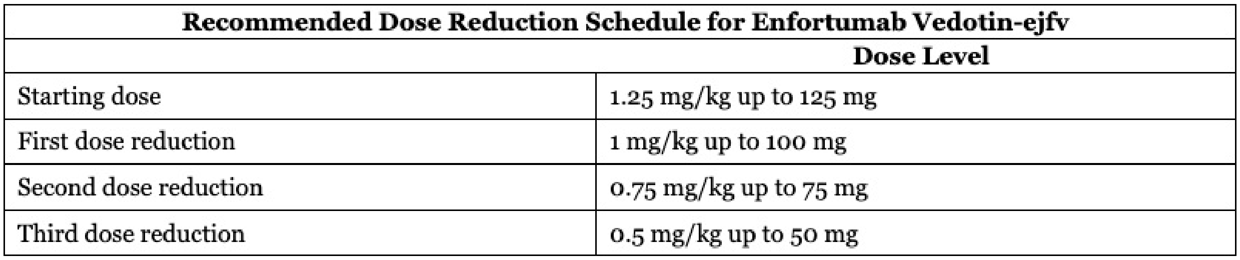
No dose adjustment required in patients with mild, moderate, or severe renal impairment or in patients with mild hepatic impairment. ■ Dose modifications for adverse reactions and indicated dose adjustments are outlined in the following charts.



Dose Modifications for Enfortumab Vedotin-ejfv Based on Adverse Reactions

Adverse Reaction	Severity[a]	Dose Modification[a]
Hyperglycemia	Blood glucose >250 mg/dL	Withhold until elevated blood glucose has improved to ≤250 mg/dL, then resume treatment at the same dose level.
Peripheral neuropathy	Grade 2	Withhold until Grade 1 or less, then resume treatment at the same dose level (if first occurrence). For a recurrence, withhold until Grade 1 or less, then resume treatment reduced by one dose level.
	Grade 3 or greater	Permanently discontinue.
Skin reactions	Grade 3 (severe)	Withhold until Grade 1 or less, then resume treatment at the same dose level or consider dose reduction by one dose level.
	Grade 4 or recurrent Grade 3	Permanently discontinue.
Other nonhematologic toxicity	Grade 3	Withhold until Grade 1 or less, then resume treatment at the same dose level or consider dose reduction by one dose level.
	Grade 4	Permanently discontinue.
Hematologic toxicity	Grade 3 or Grade 2 thrombocytopenia	Withhold until Grade 1 or less, then resume treatment at the same dose level or consider dose reduction by one dose level.
	Grade 4	Withhold until Grade 1 or less, then reduce dose by one dose level or discontinue treatment.

[a] Grade 1 is mild, Grade 2 is moderate, Grade 3 is severe, and Grade 4 is life threatening.



Recommended Dose Reduction Schedule for Enfortumab Vedotin-ejfv

	Dose Level
Starting dose	1.25 mg/kg up to 125 mg
First dose reduction	1 mg/kg up to 100 mg
Second dose reduction	0.75 mg/kg up to 75 mg
Third dose reduction	0.5 mg/kg up to 50 mg

DILUTION

Specific techniques required; see Precautions. Available as single-dose vials containing 20 mg or 30 mg of enfortumab vedotin-ejfv. For example, in a 70-kg patient:

1.25 mg/kg × 70 kg = 87.5 mg

87.5 mg ÷ 20 mg/vial = 4.375 20-mg vials, so 5 20-mg vials would be needed.

87.5 mg ÷ 30 mg = 2.91 30-mg vials, so 3 30-mg vials would be needed.

Reconstitute each 20-mg vial with 2.3 mL of SWFI (each 30-mg vial with 3.3 mL of SWFI). Direct the stream of diluent toward the side of the vial. Each vial will yield 10 mg/mL of enfortumab vedotin-ejfv. Slowly swirl each vial until the contents are completely dissolved. Allow the reconstituted vial(s) to settle for at least 1 minute until the bubbles are gone. ***Do not shake the vial(s).*** Do not expose to direct sunlight. Solution should be clear to slightly opalescent, colorless to light yellow, and free of visible particles. Withdraw the calculated dose amount of reconstituted solution from the vial(s) and transfer into an infusion bag of D5W, NS, or LR. The infusion bag size should allow enough diluent to achieve a final concentration of 0.3 mg/mL to 4 mg/mL of enfortumab vedotin-ejfv. Mix diluted solution by gentle inversion. ***Do not shake the bag.*** Do not expose to direct sunlight.

Filters:

No specific recommendations stated.

Storage:

Refrigerate vials in carton at 2° to 8° C (36° to 46° F) to protect from light. ***Do not freeze and do not shake*** in the vial, as a reconstituted solution, or as a fully diluted solution. Reconstituted vials may be refrigerated for up to 4 hours. Immediate administration of the fully diluted solution is preferred, but it may be refrigerated for no longer than 8 hours. ***Do not freeze; do not shake.***

COMPATIBILITY

Manufacturer states, “Do not mix with or administer as an infusion with other medicinal products.”

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. A single dose as an IV infusion equally distributed over 30 minutes.

ACTIONS

Enfortumab vedotin-ejfv is a nectin-4–directed antibody-drug conjugate (ADC) comprised of a fully human anti–nectin-4 IgG1 kappa monoclonal antibody (AGS-22C3) conjugated to the small-molecule microtubule disrupting agent, monomethyl auristatin E (MMAE). Neactin-4 is an adhesion protein located on the surface of cells. Nonclinical data suggest that the anticancer activity of enfortumab vedotin-ejfv is due to the binding of the ADC to nectin-4–expressing cells followed by internalization of the ADC–nectin-4 complex and the release of MMAE. Release of MMAE disrupts the microtubule network within the cell, inducing cell-cycle arrest and apoptotic cell death. Plasma protein binding of MMAE ranges from 68% to 82% in vitro. Enfortumab vedotin-ejfv is expected to undergo catabolism to small peptides, amino acids, unconjugated MMAE, and unconjugated MMAE-related catabolites. Enfortumab vedotin-ejfv releases MMAE via proteolytic cleavage, and MMAE is primarily metabolized by CYP3A4 in vitro. ADC and MMAE have multiexponential declines with an elimination half-life of 3.4 days and 2.4 days, respectively. Primarily eliminated as unchanged drug in feces and urine.

INDICATIONS AND USES

Treatment of adult patients with locally advanced or metastatic urothelial cancer (mUC) who have previously received a programmed death receptor-1 (PD-1) or programmed death-ligand 1 (PD-L1) inhibitor and a platinum-containing chemotherapy in the neoadjuvant/adjuvant, locally advanced, or metastatic setting. This indication is approved under accelerated approval based on tumor response rate. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ For IV infusion only; do not administer as an IV push or bolus. ■ Usually administered in a setting with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hyperglycemia and diabetic ketoacidosis (DKA) has occurred in patients with and without pre-existing diabetes mellitus who have been treated with enfortumab vedotin-ejfv. Deaths have occurred. Incidence of Grade 3 to 4 hyperglycemia increased consistently in patients with higher body mass index and in patients with higher baseline A1C. ■ Peripheral neuropathy, predominantly sensory, with or without pre-existing peripheral neuropathy has occurred. Median time to onset of Grade 2 or higher was 3.8 months (range 0.6 to 9.2 months) ■ Ocular disorders have occurred. The majority of these events involved the cornea and included blurred vision, dry eyes, keratitis, and limbal stem cell deficiency. ■ Skin reactions have occurred, including bullous dermatitis, exfoliative dermatitis, maculopapular rash, palmar-plantar erythrodysesthesia, pruritus, and symmetrical drug-related intertriginous and flexural exanthema (SDRIFE). ■ Skin and soft tissue reactions secondary to extravasation have been observed. Reactions may be delayed. ■ Avoid use in patients with moderate or severe hepatic impairment; enfortumab vedotin-ejfv has not been studied in these patients. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Ensure adequate venous access before starting the infusion and monitor for possible extravasation during administration. If extravasation occurs, stop the infusion and monitor for adverse reactions (e.g., erythema, increased temperature, pain, and swelling). ■ Closely monitor blood glucose levels in patients with or at risk for diabetes mellitus or hyperglycemia. ■ Monitor for symptoms of new or worsening peripheral neuropathy (numbness or tingling of the hands or feet) and consider dose interruption or dose reduction when peripheral neuropathy occurs. ■ Monitor for ocular disorders. Consider artificial tears for prophylaxis of dry eyes and ophthalmologic evaluation if symptoms occur or do not resolve. Consider ophthalmic topical steroids (if indicated after an ophthalmic exam), dose interruption, or dose reduction for symptomatic ocular disorders. ■ Monitor for skin reactions. Consider appropriate treatment such as topical corticosteroids and antihistamines as clinically indicated. ■ Monitor CBC with differential and liver function tests periodically. ■ See Dose Adjustments for treatments of adverse reactions.

Patient Education:

Verify pregnancy status of females of reproductive potential before initiating enfortumab vedotin-ejfv therapy. ■ Avoid pregnancy. Females of reproductive potential should use effective birth control during treatment and for at least 2 months after the final dose. Report a suspected pregnancy immediately. ■ Males with female sexual partners of reproductive potential should use effective contraception during treatment and for at least 4 months after the final dose. ■ Male fertility may be compromised by treatment with enfortumab vedotin-ejfv. ■ See Appendix D.

Maternal/Child:

Avoid pregnancy; based on its mechanism of action, it can cause fetal harm. ■ Discontinue breast-feeding during treatment and for at least 3 weeks after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or effectiveness were observed between older and younger patients.

DRUG/LAB INTERACTIONS

No clinical studies evaluating the drug-drug interaction potential of enfortumab vedotin-ejfv have been conducted. Another ADC drug that contains monomethyl auristatin E (MMAE) has the following drug interactions, and these interactions would likely result in similar effects on free MMAE and ADC. ■ Concomitant use with a **strong CYP3A4 inhibitor** (such as ketoconazole) may increase free MMAE exposure, which may increase the incidence or severity of enfortumab vedotin-ejfv toxicities; monitor patients receiving ketoconazole or other potent **CYP3A4 inhibitors** (e.g., clarithromycin, itraconazole, nefazodone, saquinavir) closely for adverse reactions. ■ Concomitant use with rifampin, a **strong CYAP3A4 inducer,** decreases MMAE exposure and may reduce its effectiveness.

SIDE EFFECTS

Alopecia, decreased appetite, diarrhea, dry eye, dry skin, dysgeusia, peripheral neuropathy, pruritus, and rash are most common. Fatigue, nausea, and vomiting have also been reported. Laboratory abnormalities include decreased hemoglobin, lymphocytes, neutrophils, and leukocytes; decreased phosphate, potassium, and sodium; and increased creatinine, glucose, lipase, and urate. The most common serious reactions include acute kidney injury, cellulitis, diarrhea, dyspnea, febrile neutropenia, rash, sepsis, and urinary tract infections. Serious reactions include hyperglycemia, infusion site extravasation, ocular disorders, peripheral neuropathy, and skin reactions.

ANTIDOTE

Notify physician of all side effects. Treatment of some reactions will be supportive. Dose delay, dose modification, or discontinuation of therapy may be required in hyperglycemia, infusion site extravasation, ocular disorders, peripheral neuropathy, and/or skin reactions; see Dose Adjustments and Monitor. Resuscitate as necessary.

EPHEDRINE SULFATE

(eh-**FED**-rin **SUL**-fayt)
Akovaz, Corphedra
Alpha- and beta-adrenergic agonist
Vasopressor
pH 4.5 to 7

USUAL DOSE

5 to 10 mg; administer additional boluses as needed, titrating to effect. Do not exceed a total dose of 50 mg.

PEDIATRIC DOSE (UNLABELED)

One source recommends 0.1 to 0.2 mg/kg/dose by slow IV push; administer as needed to maintain blood pressure, not to exceed a total dose of 25 mg.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly based on the potential for decreased renal function and concomitant disease or drug therapy. See Drug/Lab Interactions.

DILUTION

Available as a 50 mg/mL single-dose vial. Must be diluted to a final concentration of 5 mg/mL with D5W or NS before administration by withdrawing 1 mL (50 mg) of ephedrine and diluting with 9 mL of D5W or NS. Withdraw appropriate volume of diluted solution to provide desired dose (e.g., 1 mL equals a 5-mg dose) and administer as an IV bolus.

Filters:

No data available from manufacturer.

Storage:

Store at CRT in carton until time of use to protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as a slow IV push. Rate not specified by manufacturer.

ACTIONS

A sympathomimetic drug that stimulates both alpha- and beta-adrenergic receptors and stimulates the release of norepinephrine. Pressor effects by direct alpha- and beta-adrenergic receptor activation are mediated by increases in arterial pressures, cardiac output, and peripheral resistance. Indirect adrenergic stimulation is caused by norepinephrine release from sympathetic nerves. It is less potent but longer acting than epinephrine. Stimulates heart rate and cardiac output and variably increases peripheral resistance; as a result, ephedrine usually increases blood pressure. Widely distributed in body fluids. Metabolized in the liver (exact metabolic pathway unknown) and excreted in urine. Urinary excretion is dependent on pH of urine; see Drug/Lab Interactions. Crosses the placental barrier and is secreted in breast milk.

INDICATIONS AND USES

Treatment of clinically important hypotension occurring in the setting of anesthesia.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Repeated administration of ephedrine can result in tachyphylaxis. An alternative pressor should be available, if needed, to mitigate unacceptable responsiveness. ■ When used to *prevent* hypotension (prophylactic use), ephedrine has been associated with an increased incidence of hypertension compared with when it is used to *treat* hypotension.

Monitor:

Check BP and HR. ■ In patients with renal impairment, elimination half-life may be increased, resulting in prolonged pharmacologic effect and potential adverse reactions. Monitor carefully after initial bolus. ■ See Drug/Lab Interactions.

Maternal/Child:

Limited published data; determine risk versus benefit. Cases of potential metabolic acidosis in newborns at delivery with maternal ephedrine exposure have been reported; monitoring of newborn for S/S of metabolic acidosis may be required. ■ Safety for use in breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Differences in response have not been identified between the elderly and younger patients. In general, dose range for the elderly should be cautious, usually starting at the low end of the dosing range.

DRUG/LAB INTERACTIONS

Serious postpartum hypertension has been reported in patients who received both a vaso-pressor (e.g., ephedrine) and an **oxytocic** (e.g., methylergonovine, ergonovine, oxytocin). Monitor BP in patients who receive both ephedrine and an oxytocic. ■ Do not use concomitantly with **other sympathomimetic agents** (e.g., dopamine, dobutamine, epinephrine). Additive effects may cause toxicity. ■ **Atropine, clonidine, MAO inhibitors**, and **propofol** increase pressor response. Monitor BP carefully. ■ **Digoxin** may sensitize myocardium and increase the risk of arrhythmias. ■ **Alpha-adrenergic antagonists, beta-adrenergic antagonists, reserpine**, and **quinidine** are examples of drugs that may antagonize the pressor effects of ephedrine, decreasing its effectiveness. Monitor blood pressure. ■ Antihypertensive effect of **guanethidine** may be decreased; monitor carefully. ■ May reduce the onset of neuromuscular blockade when used for intubation with **rocuronium** if administered simultaneously with the anesthetic induction. ■ May decrease the efficacy of **epidural anesthesia blockade** by hastening the regression of sensory analgesia. Monitor and treat the patient according to clinical practice. ■ Use with **theophylline** may increase cardiac, CNS, and GI side effects. ■ Interacts with many other drugs.

SIDE EFFECTS

The most common adverse reactions are nausea, vomiting and tachycardia. Other reported adverse reactions include bradycardia, dizziness, palpitations, reactive hypertension, restlessness, and ventricular ectopics.

ANTIDOTE

If side effects occur, discontinue drug and notify physician. Side effects may be treated symptomatically. Monitor BP carefully. If BP continues to rise to an unacceptable level, parenteral antihypertensive agents can be administered at the discretion of the clinician. Resuscitate as necessary.

EPINEPHRINE HYDROCHLORIDE

(ep-ih-**NEF**-rin hy-droh-**KLOR**-eyed)
Adrenalin Chloride
Alpha/beta adrenergic agonist
Vasopressor
pH 2.5 to 5

USUAL DOSE

Hypotension associated with septic shock:

0.05 to 2 mcg/kg/min. Titrate in increments of 0.05 to 0.2 mcg/kg/min every 10 to 15 minutes to achieve a desired mean arterial pressure (MAP). ACLS guidelines recommend an initial dose of 0.1 to 0.5 mcg/kg/min with titration to desired response. After hemodynamic stabilization, wean the epinephrine infusion incrementally over time, such as by decreasing doses every 30 minutes over a 12- to 24-hour period.

Treatment of anaphylaxis:

IM administration in the thigh is preferred in the setting of anaphylaxis. IV administration should be reserved for patients who are unresponsive or profoundly hypotensive and who have failed to respond to IV fluid replacement and several epinephrine injections.

Slow IV bolus:

0.1 mg using a **0.1 mg/mL** solution administered over 5 to 10 minutes.

Continuous infusion:

Initiate at 2 to 15 mcg/min (with crystalloid administration).

Bradycardia (symptomatic; unresponsive to atropine or pacing):

ACLS guidelines recommend an epinephrine infusion at 2 to 10 mcg/min **or** 0.1 to 0.5 mcg/kg/min. Titrate to desired effect.

Cardiac arrest:

ACLS guidelines recommend 1 mg (10 mL of a 0.1 mg/mL concentration) IV; may repeat every 3 to 5 minutes. Follow each dose with a 20-mL IV flush to ensure delivery to systemic circulation. See Compatibility. Doses up to 0.2 mg/kg have been used for specific indications (beta-blocker or calcium channel blocker overdose). May also be given as a continuous infusion by adding 1 mg of epinephrine (1 mL of a 1 mg/mL solution) to 500 mL NS or D5W. Begin with an infusion rate of 0.1 to 0.5 mcg/kg/min and titrate to response. The dose for a 70-kg patient would be 7 to 35 mcg/min. Higher doses of epinephrine (greater than 1 mg) are controversial; have not been shown to improve survival or neurologic outcomes compared with standard dose epinephrine and are not recommended.

Endotracheal:

A diluted solution may be given through the endotracheal tube before an IV is established. ACLS guidelines recommend 2 to 2.5 mg (of a 1 mg/mL solution) diluted in 10 mL NS.

PEDIATRIC DOSE

Hypersensitivity reactions or bronchospasm in infants and children:

See comments under Usual Dose. 0.01 mg/kg (0.1 mL/kg of a 0.1 mg/mL concentration). May repeat at 20-minute to 4-hour intervals. One source suggests a maximum dose of 0.3 mg.

Severe anaphylactic shock in infants and children:

One source suggests 0.1 mg IV of a 0.01 mg/mL concentration (0.1 mL of a 1 mg/mL concentration diluted in 10 mL NS) given over 5 to 10 minutes. Another source suggests 0.01 mL/kg of a 1 mg/mL concentration SC. Maximum 0.5 mL/dose.

Bradycardia (symptomatic; unresponsive to atropine or pacing) in infants and children:

PALS guidelines recommend 0.01 mg/kg (0.1 mL/kg of a 0.1 mg/mL concentration) (maximum dose: 1 mg) every 3 to 5 minutes as needed. If IV access is not readily available, guidelines recommend 0.1 mg/kg (0.1 mL/kg of a 1 mg/mL concentration) via ET (maximum single dose: 2.5 mg) every 3 to 5 minutes as needed.

Asystolic or pulseless arrest in infants and children:

PALS guidelines recommend 0.01 mg/kg (0.1 mL/kg of a 0.1 mg/mL concentration) (maximum single dose: 1 mg). Repeat every 3 to 5 minutes during arrest. May be given via ET (0.1 mg/kg [0.1 mL/kg of a 1 mg/mL concentration]) (maximum single dose: 2.5 mg) every 3 to 5 minutes until IV established, then begin with first IV dose.

Asystolic or pulseless arrest in neonates:

PALS guidelines recommend 0.01 to 0.03 mg/kg (0.1 to 0.3 mL/kg of a 0.1 mg/mL concentration) initially. May repeat every 3 to 5 minutes.

DOSE ADJUSTMENTS

Lower-end initial dosing may be appropriate in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

New changes in labeling eliminate the use of ratios; what was previously a 1:1,000 solution will now be referred to only as a 1 mg/mL solution, a 1:10,000 solution will now be referred to only as a 0.1 mg/mL solution, and a 1:100,000 solution will now be referred to only as a 0.01 mg/mL solution.

Check label. Not all epinephrine solutions can be given IV. The 1 mg/mL strength is for SC or IM use only. It must be further diluted with 9 mL of NS to prepare a 0.1

mg/mL solution before IV or ocular use.

1 mg (1 mL) mixed in 9 mL = 1 mg/10 mL = 0.1 mg/mL solution

1 mg (1 mL) mixed in 99 mL = 1 mg/100 mL = 0.01 mg/mL

IV injection:

Available prediluted (0.1 mg/mL) in 10-mL syringes. Available in a 30-mL vial (30 mg [1 mg/mL solution]). Each 1 mg (1 mL) of 1 mg/mL solution must be diluted in 9 mL of NS to prepare a 0.1 mg/mL solution.

Infusion:

Manufacturer recommends diluting 1 mg in 1000 mL of D5W or a 5% dextrose and sodium chloride solution to provide an infusion solution with a final concentration of 1 mcg/mL. Other commonly used infusion concentrations are 1 mg in 250 mL (concentration: 4 mcg/mL) or 4 mg in 250 mL (concentration: 16 mcg/mL). In pediatric patients, commonly used infusion concentrations are 16 mcg/mL, 32 mcg/mL, or 64 mcg/mL. See chart on inside back cover for additional **compatible** solutions.

Filters:

No data available from manufacturer.

Storage:

Store at CRT unless otherwise specified by manufacturer. Do not refrigerate. Do not use if colored or cloudy or contains particulate matter. Deteriorates rapidly. Protect from light and freezing.

COMPATIBILITY

Manufacturer states, “Readily destroyed and precipitate forms with alkalis, alkaline solutions (e.g., sodium bicarbonate and oxidizing agents).” ***If coadministration with sodium bicarbonate is indicated, give at separate sites.*** Manufacturer also states that dilution in dextrose-containing solutions provides protection against significant loss of potency by oxidation and that ***administration in saline solution alone is not recommended***. (However, another source says that epinephrine is stable in NS.) Unstable in any solution with a pH over 5.5 (e.g., aminophylline, ampicillin, lidocaine, warfarin). Administration of whole blood or plasma, if needed, should be given through a separate line.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Some sources recommend giving IV doses for treatment of hypersensitivity reactions over 5 to 10 minutes. May be given more rapidly in cardiac resuscitation; follow with 20-mL IV flush.

Infusion:

See Usual Dose. Must be delivered by central venous access (preferred) or through a large vein. Use an infusion pump to control rate.

ACTIONS

A naturally occurring hormone secreted by the adrenal glands. A sympathomimetic drug, it imitates almost all actions of the sympathetic nervous system. Stimulates both alpha- and beta-adrenergic receptors. The mechanism of the rise of blood pressure is threefold: (1) a direct myocardial stimulation that increases the strength of the ventricular contraction (positive inotropic action), (2) an increased heart rate (positive chronotropic action), and (3) peripheral vasoconstriction. Most vascular beds are constricted, including renal, splanchnic, mucosal, and skin. Decreases in systemic vascular resistance and diastolic BP are seen at lower doses. At higher doses, alpha-mediated vasoconstriction leads to an increase in diastolic BP. Onset of action for elevating blood pressure is less than 5 minutes. Time to offset of blood pressure response occurs within 20 minutes. When used for treatment of anaphylaxis, epinephrine lessens the vasodilation and increased vascular permeability that occurs during anaphylaxis and can lead to a loss of intravascular fluid volume and hypotension. Epinephrine causes bronchial smooth muscle relaxation and helps alleviate bronchospasm, wheezing, and dyspnea. It also helps to alleviate pruritus, urticaria, and angioedema and may relieve gastrointestinal and genitourinary symptoms because of its relaxant effects on the smooth muscle of the stomach, intestine, uterus, and urinary bladder. Has a rapid onset of action. Steady state is achieved within 10 to 15 minutes of starting an infusion. Half-life is less than 5 minutes. It is rapidly and extensively metabolized and is excreted in changed form in the urine. Crosses placental barrier.

INDICATIONS AND USES

Treatment of hypotension associated with septic shock in adult patients. (Used to increase mean arterial pressure [MAP].) ■ Emergency treatment of type I allergic reactions (including anaphylaxis) that may result from allergic reactions to insect stings, insect bites, foods, drugs, sera, diagnostic testing substances, and other allergens, as well as idiopathic anaphylaxis or exercise-induced anaphylaxis. S/S associated with anaphylaxis include flushing, apprehension, syncope, tachycardia, thready or unobtainable pulse associated with hypotension, convulsions, vomiting, diarrhea and abdominal cramps, involuntary voiding, airway swelling, laryngospasm, bronchospasm, pruritus, urticaria or angioedema, and swelling of the eyelids, lips, and tongue. ■ Induction and maintenance of mydriasis during intraocular surgery (given as an intraocular irrigation).

Unlabeled indications:

Acute, severe asthma unresponsive to an inhaled beta-agonist; asystole/pulseless arrest, ventricular fibrillation, or pulseless ventricular tachycardia; bradycardia unresponsive to atropine or pacing; hypotension/shock unresponsive to volume resuscitation; inotropic support.

CONTRAINDICATIONS

One manufacturer states, “None.” Some manufacturers and sources list the following potential contraindications: anesthesia with halogenated hydrocarbons or cyclopropane, cerebral arteriosclerosis, diabetes, hypersensitivity to sympathomimetic amines, hypertension and other cardiovascular disorders, labor and delivery if maternal BP exceeds 130/80 mm Hg, labor (may delay second stage), narrow-angle glaucoma, non-anaphylactic shock, organic brain damage. There are no absolute contraindications in a life-threatening situation.

PRECAUTIONS

Usual route is SC or IM except in cardiac resuscitation or as a vasopressor infusion. ■ Correct blood volume depletion as fully as possible before administration. In an emergency situation (e.g., intra-aortic pressures must be maintained to prevent cerebral or coronary artery ischemia), epinephrine can be administered before and concurrently with blood volume replacement. ■ Because of varying responses to epinephrine, dangerously high blood pressure can occur; see Monitor and Drug/Lab Interactions. ■ Tissue necrosis can occur with extravasation. Blanching along the course of the vein, sometimes without obvious extravasation, may be attributed to constriction of the vasa vasorum (small blood vessels that supply or drain the walls of the larger arteries and veins and connect with a branch of the same vessel or a neighboring vessel). This constriction may result in increased permeability of the vein wall, permitting some leakage that, rarely, may progress to a superficial slough. If blanching occurs, consider changing infusion site. ■ Pulmonary edema may occur as a result of the peripheral constriction and cardiac stimulation that is produced; see Antidote. Constriction of renal blood vessels may result in decreased urine formation. ■ Epinephrine may induce cardiac arrhythmias and angina pectoris. Risk is increased in patients with coronary artery disease, organic heart disease, cerebrovascular disease, or hypertension or in patients who are receiving drugs that sensitize the myocardium. ■ Use caution in elderly patients, pregnant women, and patients with diabetes (may experience transient increases in blood sugar), hyperthyroidism, pheochromocytoma, and Parkinson’s disease (may experience psychomotor agitation or a temporary worsening of symptoms). ■ Higher doses may be required to treat poison-induced shock. ■ Manufacturer lists additional precautions for nonintravenous routes.

Monitor:

Monitor vital signs. Invasive arterial blood pressure monitoring and central venous pressure monitoring are recommended. Dangerously high blood pressure can occur with IV administration. ■ Monitoring of ECG and serum potassium and glucose concentrations may be indicated. ■ Epinephrine is a vesicant. Frequent monitoring of IV infusion site is required. Whenever possible, administer infusion into a large vein; central line administration is preferred. Avoid administering in areas of limited blood supply (e.g., fingers, toes) or if peripheral vascular disease is present. Occlusive vascular diseases (e.g., atherosclerosis, arteriosclerosis, diabetic endarteritis, Buerger’s disease) are more likely to occur in the lower extremity than in the upper extremity; avoid veins of the legs in elderly patients or in patients suffering from occlusive vascular diseases. ■ Monitor urinary output. ■ See Drug/Lab Interactions.

Patient Education:

Review potential side effects with patient or caregiver (e.g., anxiety, apprehension, difficulty breathing, dizziness, forceful heartbeat, headache, increase in HR, nausea, nervousness, pallor, palpitations, shakiness, sweating, vomiting, and weakness). These S/S usually subside rapidly, especially with rest, quiet, and recumbent positioning. ■ Symptoms of anaphylaxis may recur following successful treatment. Seek medical help if needed. ■ Increases in blood glucose levels may occur following administration of epinephrine.

Maternal/Child:

Category C: assess risk versus benefit; may cause fetal anoxia, spontaneous abortion, or both. ■ Avoid use in obstetrics when maternal blood pressure exceeds 130/80 mm Hg. ■ Use caution during labor and delivery. Inhibits spontaneous or oxytocin-induced contractions and may delay the second stage of labor. In doses sufficient to reduce uterine contraction, epinephrine may cause a prolonged period of uterine atony with hemorrhage. Although epinephrine improves maternal hypotension associated with anaphylaxis, it may result in uterine vasoconstriction, decreased uterine blood flow, and fetal anoxia. ■ Use caution in breast-feeding. ■ Safety and effectiveness in pediatric patients with septic shock have not been established. Clinical use data support weight-based dosing for treatment of anaphylaxis and suggest that the adverse reactions seen in children are similar in nature and extent to those reported for adults.

Elderly:

Data are limited. May be more sensitive to the effects of beta-adrenergic receptor agonists (e.g., hypertension, hypokalemia, tachycardia, tremor). Patients with cardiac disease may be at increased risk for adverse effects. ■ Dose selection should be cautious in the elderly; see Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

May be used alternately with isoproterenol (Isuprel), but they may not be used together. Both are direct cardiac stimulants, and concomitant use may increase the risk of arrhythmia. Adequate interval between doses must be maintained. ■ **Oxytocics** (e.g., oxytocin), **other sympathomimetic agents** (e.g., ephedrine, dopamine), **MAO inhibitors, nonselective beta-adrenergic blockers** (e.g., propranolol), **tricyclic antidepressants, catechol-O-methyltransferase (COMT) inhibitors** (e.g., entacapone), **and clonidine** potentiate the pressor effects of epinephrine; may result in hypertension or cause hypertensive crisis. ■ **Alpha-blockers, vasodilators** (e.g., nitrates), **diuretics, antihypertensives, and ergot alkaloids** may antagonize the pressor effects of epinephrine. ■ Epinephrine may antagonize the neuronal blockade produced by **guanethidine**, resulting in a decreased antihypertensive effect and requiring increased dosage of the latter. ■ Epinephrine should not be used to counteract circulatory collapse or hypotension caused by **phenothiazines**, because a reversal of the pressor effects of epinephrine may result in further lowering of blood pressure. ■ **Hydrocarbon anesthetics** (e.g., enflurane, halothane), **digoxin, nonselective beta-adrenergic blockers** (e.g., propranolol), **antihistamines, thyroid hormone, diuretics, and quinidine** may increase the risk of arrhythmias; monitor patients who must receive concomitant use. ■ Use with **theophylline, potassium-depleting diuretics, and corticosteroids** may potentiate the hypokalemic effects of epinephrine. ■ Interacts with many other drugs.

SIDE EFFECTS

The most commonly reported adverse reactions associated with the IV administration of epinephrine include anxiety, apprehensiveness, dizziness, headache, nausea, pallor, palpitations, peripheral coldness, restlessness, respiratory difficulties, sweating, tremor, vomiting, and weakness. Arrhythmias (including fatal ventricular fibrillation), rapid rises in blood pressure producing cerebral hemorrhage, and angina have occurred. Other reported reactions include chest pain, diaphoresis, excitability, extravasation, hyperglycemia, hypoglycemia, hypokalemia, insulin resistance, lactic acidosis, limb ischemia, MI, myocardial ischemia, nervousness, paresthesia, piloerection, pulmonary edema, rales, renal insufficiency, skin blanching, skin necrosis with extravasation, stroke, supraventricular tachycardia, tachycardia, ventricular arrhythmias.

Overdose (frequently caused by too-rapid injection):

Arrhythmia (atrial and ventricular), bradycardia (transient followed by tachycardia), cardiomyopathy, cerebrovascular hemorrhage, extreme pallor and coldness of the skin, hypertension, metabolic acidosis due to elevated lactic acid levels, myocardial ischemia or infarction, pulmonary edema, pupillary dilation, renal failure, tachycardia, death.

ANTIDOTE

Treatment is primarily supportive. If side effects from the average dose become progressively worse, discontinue the drug and notify the physician. IM or SC route may be preferable. To prevent sloughing and necrosis in areas in which extravasation has occurred, use a fine hypodermic needle to inject 5 to 10 mg of phentolamine diluted in 10 to 15 mL NS liberally throughout the tissue in the affected area. Begin as soon as extravasation is recognized. Treatment of pulmonary edema consists of a rapidly acting alpha-adrenergic blocking agent (such as phentolamine) and respiratory support. Pressor effects may be counteracted by rapidly acting vasodilators (e.g., nitrates) or alpha-adrenergic blocking agents (e.g., phentolamine). If prolonged hypotension follows such measures, it may be necessary to administer another pressor drug. Treat cardiac arrhythmias with a beta-adrenergic blocker. Resuscitate as necessary.

EPIRUBICIN HYDROCHLORIDE **BBW**

(ep-ee-**ROO**-bih-sin hy-droh-**KLOR**-eyed)
Ellence ■ Pharmorubicin PFS 🍁
Antineoplastic (anthracycline antibiotic)
pH 3 ■ pH 4 to 5.5

USUAL DOSE

Ellence

Pretreatment:

Verify pregnancy status. Preassessment and baseline studies required; see Monitor.

Premedication:

Consider use of antiemetics before administration of epirubicin or when clinically indicated to reduce nausea and vomiting, particularly when given in conjunction with other emetigenic drugs.

Epirubicin:

Recommended starting dose is 100 to 120 mg/M^2. Administer as an IV injection over 15 to 20 minutes through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W. Patients receiving the 120-mg/M^2 dose should also receive prophylactic antibiotic therapy with sulfamethoxazole/trimethoprim or a fluoroquinolone (e.g., ciprofloxacin [Cipro]). Ellence is usually given in repeated 3- to 4-week cycles. Total dose may be given on Day 1 of each cycle or equally divided and given on Days 1 and 8 of each cycle.

One regimen used is 60 mg/M^2 of epirubicin intravenously on Days 1 and 8 given in a regimen with oral cyclophosphamide 75 mg/M^2 on Days 1 to 14 and fluorouracil 500 mg/M^2 on Days 1 and 8. Repeat every 28 days for six cycles. Another regimen used is 100 mg/M^2 of epirubicin intravenously together with fluorouracil 500 mg/M^2 and cyclophosphamide 500 mg/M^2. All three agents are given on Day 1 and are repeated every 21 days for 6 cycles. In either regimen the total dose of epirubicin may be given on Day 1 of each cycle or equally divided and given on Days 1 and 8 of each cycle.

🍁 Pharmorubicin PFS

Metastatic breast cancer:

Single agent: 75 to 90 mg/M^2 once every 21 days. This dose may be divided and given on Day 1 and Day 2. An alternative weekly dose schedule of 12.5 to 25 mg/M^2 has been used and has been reported to produce less clinical toxicity than higher doses given every 3 weeks. ***Combination therapy:*** 50 mg/M^2. Used in combination with cyclophosphamide and fluorouracil.

Early-stage breast cancer (Stage II-IIIA):

50 to 60 mg/M^2 given on Days 1 and 8 every 4 weeks. Used in combination with cyclophosphamide and fluorouracil.

Small-cell lung cancer:

Single agent: 90 to 120 mg/M^2 once every 3 weeks. ***Combination therapy:*** 50 to 90 mg/M^2. Several combinations have been used (e.g., with either cisplatin or ifosfamide; with cyclophosphamide and vincristine; with cyclophosphamide and etoposide; or with cisplatin and etoposide).

Non–small-cell lung cancer:

Single agent: 120 to 150 mg/M^2 on Day 1 every 3 to 4 weeks. ***Combination***

therapy: 90 to 120 mg/M^2 on Day 1 every 3 to 4 weeks. Used in combination with cisplatin, etoposide, mitomycin, and vinblastine.

Non-Hodgkin lymphoma:

Single agent: 75 to 90 mg/M^2 once every 3 weeks. ***Combination therapy:*** 60 to 75 mg/M^2. Used in combination with cyclophosphamide, prednisone, and vincristine with or without bleomycin for the treatment of newly diagnosed non-Hodgkin lymphoma.

Hodgkin disease:

Combination therapy:

35 mg/M^2 once every 2 weeks or 70 mg/M^2 once every 3 to 4 weeks. Used in combination with bleomycin, dacarbazine, and vinblastine.

Ovarian cancer:

Single agent: 50 to 90 mg/M^2 once every 3 or 4 weeks in patients who have had prior therapy. ***Combination therapy:*** 50 to 90 mg/M^2 once every 3 or 4 weeks can be added to their regimen in patients who have had prior therapy; or the same dose in combination with cisplatin and cyclophosphamide is used for initial therapy of ovarian cancer.

Locally unresectable or metastatic gastric cancer:

Single agent: 75 to 100 mg/M^2 once every 3 weeks. ***Combination therapy:*** 80 mg/M^2 once every 3 to 4 weeks. Used in combination with fluorouracil.

DOSE ADJUSTMENTS

All Formulations:

Reduced dose required with elevated serum bilirubin. Give 50% of a dose for serum bilirubin from 1.2 to 3 mg/dL or AST 2 to 4 times the ULN. Give 25% of a dose for serum bilirubin greater than 3 mg/mL or AST greater than 4 times the ULN.

Ellence:

Consider reducing starting dose to 75 to 90 mg/M^2 in heavily pretreated patients, those with pre-existing bone marrow suppression, or in the presence of neoplastic bone marrow infiltration. ■ Consider reduced dose in patients with severe renal impairment (SCr greater than 5 mg/dL). ■ Base dose adjustments after the first treatment cycle on hematologic response during treatment cycle nadir and nonhematologic toxicities. In patients who received the full dose on Day 1, reduce dose to 75% of initial first dose in subsequent cycles for platelet count less than 50,000/mm^3, absolute neutrophil count (ANC) less than 250/mm^3, neutropenic fever, or Grade 3 or 4 nonhematologic toxicity. Delay dose in subsequent treatment cycles until platelet count recovers to at least 100,000/mm^3, ANC recovers to at least 1,500/mm^3, and nonhematologic toxicities have recovered to equal to or less than Grade 1. For patients receiving a divided dose, reduce the Day-8 dose to 75% of the Day-1 dose if platelet counts are 75,000 to 100,000/mm^3 and ANC is 1,000 to 1,499/mm^3. Omit the Day-8 dose if platelet counts are less than 75,000/mm^3, ANC less than 1,000/mm^3, or Grade 3 or 4 nonhematologic toxicity has occurred.

🍁 Pharmorubicin PFS:

Use lower dose in range for patients with inadequate marrow reserves due to old age, prior therapy, or neoplastic marrow infiltration. ■ Reduced dose, delay, or suspension of epirubicin may be required based on hematologic toxicity; manufacturer provides no specific recommendations. ■ No dose adjustment required in impaired renal function.

DILUTION

Specific techniques required; see Precautions.

Ellence:

Available as 2 mg/mL in 25-mL and 100-mL vials. A ready-to-use, preservative-free solution; further dilution not required. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W.

🍁 Pharmorubicin PFS:

Available as 2 mg/mL in 5-mL, 25-mL, and 100-mL vials. Use of the 100-mL vial should be restricted to a pharmacy admixture program using a sterile transfer or dispensing device. Enter any vial only once and withdraw desired dose into a syringe. No further dilution is required.

Filters:

Manufacturer indicates that studies show some initial potency loss in the first few minutes with the use of cellulose ester membrane or nylon filters; however, the total amount of drug loss is negligible. A second source has a similar statement.

Storage:

Ellence:

Refrigerate vials at 2° to 8° C (34° to 46° F); protect from light. Do not freeze. Refrigeration may result in a gel-formed product; will return to a slightly viscous to mobile solution within 2 to 4 hours. Must be used within 24 hours of removal from refrigeration. Discard unused solution.

🍁 Pharmorubicin:

Store unopened PFS vials in refrigerator; keep in original cartons to protect from light. Use any filled syringe within 24 hours if stored at room temperature and within 48 hours if refrigerated. Syringes prepared from the pharmacy bulk vial must be used within 24 or 48 hours of the initial puncture of that vial based on method of storage. Once the transfer set has been inserted in the bulk vial, any remaining undispensed drug must be discarded in 8 hours.

COMPATIBILITY

Manufacturers recommend not mixing with other drugs in the same syringe. Avoid prolonged contact with alkaline solutions; will result in hydrolysis of all forms of epirubicin. Do not mix with heparin or fluorouracil (5-FU); may precipitate. **Incompatible** with ifosfamide (Ifex) when combined in syringe or solution with mesna (Mesnex). Can be used with other antitumor agents, but do not mix in the same syringe.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

All formulations:

An initial starting dose of 100 to 120 mg/M^2 should be infused over 15 to 20 minutes. Lower starting doses or modified doses may be administered over a minimum of 3 minutes and up to 20 minutes. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of NS or D5W. Slow injection rate further for erythematous streaking along the vein or facial flushing.

ACTIONS

A semi-synthetic, anthracycline, antineoplastic antibiotic agent. Exact method of action is unknown. Rapidly and widely distributed into tissue. Inhibits DNA, RNA, and protein synthesis and interferes with replication and transcription. Free radicals cause further cytotoxic activity. Metabolized in the liver and by other organs and cells, including RBCs. WBC nadir is reached in 10 to 14 days and should return to normal by Day 21. Elimination half-life is 30 to 40 hours. Does not cross blood-brain barrier. Primarily excreted in bile; some excretion in urine.

INDICATIONS AND USES

Ellence:

A component of adjuvant therapy in patients with evidence of axillary-node tumor involvement following resection in primary breast cancer.

🍁 Pharmorubicin:

Treatment of metastatic as well as early-stage breast cancer, small-cell lung cancer (both limited and extensive disease), advanced non–small-cell lung cancer, non-Hodgkin lymphoma, Hodgkin disease, Stage III and IV ovarian cancer, and metastatic and locally unresectable gastric cancers. May be used as a single agent or in combination with other chemotherapeutic agents.

Unlabeled uses: All Formulations:

Treatment of soft-tissue sarcomas in combination with other agents. Treatment of esophageal and esophagogastric junction cancers in combination with other agents.

Ellence has been used in place of Pharmorubicin for various indications.

CONTRAINDICATIONS

Patients with severe myocardial insufficiency, recent myocardial infarction, or severe arrhythmias. ■ Severe persistent drug-induced myelosuppression. ■ Severe hepatic impairment (defined as Child-Pugh Class C or serum bilirubin level greater than 5 mg/dL). Contraindicated in patients who have received previous treatment with maximum recommended cumulative doses of epirubicin, other anthracyclines, or anthracenediones (e.g., daunorubicin [Cerubidine], doxorubicin [Adriamycin], idarubicin [Idamycin], mitoxantrone [Novantrone], or mitomycin C). ■ Severe hypersensitivity to epirubicin, other anthracyclines, or anthracenediones.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ May cause severe myelosuppression, resulting in serious infection, septic shock, requirement of transfusions, hospitalizations and death may occur. ■ Epirubicin and other anthracycline drugs can result in early (acute) or late (delayed) cardiac toxicity. ■ Prior history of cardiovascular disease, prior or concomitant radiotherapy to the mediastinal/pericardial area, previous therapy with other anthracyclines or anthracenediones, and concomitant use of other cardiotoxic drugs increase the risk of developing late cardiac toxicity. ■ Cumulative doses of 900 mg/M^2 should generally be avoided. ■ Myocardial damage, including acute left ventricular failure, can occur. ■ The risk of cardiomyopathy Is further Increased with concomitant cardiotoxic therapy. ■ Cardiotoxicity may occur at lower cumulative doses whether or not cardiac risk factors are present. ■ Patients are at increased risk of developing cardiotoxicity with epirubicin after stopping treatment with other cardiotoxic drugs, especially those with long half-lives (e.g., trastuzumab). ■ Epirubicin can increase radiation-induced toxicity to the myocardium, mucosa, skin, and liver. Radiation recall, including but not limited to cutaneous and pulmonary toxicity, can occur in patients after prior radiation therapy. ■ Secondary acute myelogenous leukemia (AML) and myelodysplastic syndrome (MDS) occur at a higher Incidence in patients treated with anthracyclines. The cumulative probability of developing AML/MDS is particularly increased in patients who have received more than 720 mg/M^2 of epirubicin or more than 6,300 mg/M^2 of cyclophosphamide. ■ Thrombophlebitis and thromboembolic events, including pulmonary embolism, have been reported.

Monitor:

Obtain baseline CBC, including differential and platelet count; serum calcium, phosphate, and potassium; SCr; uric acid level; liver function tests (AST, ALT, alkaline phosphatase, and serum bilirubin). ■ Obtain baseline cardiac evaluations with an ECG and evaluation of left ventricular ejection fraction (LVEF). ■ Monitor LVEF during the course of treatment and consider discontinuation if LVEF decreases or S/S of CHF develop. ■ Monitor lab values during therapy, especially before each dose. ■ Monitor ECG, chest x-ray, echocardiogram, and/or radionuclide angiography in patients who have had mediastinal radiation, other anthracycline or anthracene therapy, those with pre-existing cardiac disease or S/S of impending heart disease, or those who have received prior epirubicin cumulative doses exceeding 550 mg/M². ■ Monitor for signs of cardiac toxicity (e.g., rapid or irregular HR, shortness of breath, swelling of abdomen, feet, and lower legs); early signs usually include sinus tachycardia and nonspecific ST-T wave changes in the ECG; late signs include reduced LVEF and or S/S of CHF. If late cardiac toxicity occurs, it usually develops late during therapy or within 2 to 3 months after completion of treatment, but occurrences of months to years after treatment have happened. ■ Closely monitor patients with other risk factors for cardiac toxicity, particularly prior administration of anthracycline or anthracenedione. ■ Use only large veins. Avoid veins over joints or in extremities with compromised venous or lymphatic drainage. Determine absolute patency of vein. Extravasation may occur with or without stinging or burning along the injection site even if blood returns well on aspiration of the infusion needle. Observe site frequently. Extravasation can result in severe local tissue injury and tissue necrosis; if it occurs, discontinue injection. Use another vein; see Antidote. ■ Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, uric acid–lowering drugs (e.g., allopurinol [Aloprim]). ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Use of prophylactic antibiotics may be indicated pending C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm³). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antiemetics are indicated. ■ See Drug/Lab Interactions.

Patient Education:

Urine will be reddish for several days (from drug, not hematuria). ■ Females of reproductive potential must use effective contraception during treatment and for 6 months after the last dose. ■ Male patients with female partners of reproductive potential must use effective contraception during treatment and for 3 months after the last dose. Male patients with pregnant partners must use condoms during treatment and for at least 7 days after the last dose. May cause amenorrhea and premature menopause in women and oligospermia, azoospermia, and permanent loss of fertility in men. ■ Report IV site burning, stinging, or puffiness promptly. ■ Report dizziness, light-headedness, rapid or irregular HR, shortness of breath, and swelling of the abdomen, feet, or lower legs. ■ Report vomiting, dehydration, fever, or other evidence of infection. ■ Review side effects; may be severe (e.g., nausea and vomiting, cardiotoxicity). ■ See Appendix D, p. 1311.

Maternal/Child:

Based on its mechanism of action, can cause fetal harm. Avoid pregnancy. ■ Discontinue breast-feeding during treatment and for at least 7 days after the last dose. ■ Information on safety for use in pediatric patients not available. Some studies suggest that pediatric patients may be at greater risk for anthracycline-induced acute cardiotoxicity and/or late cardiovascular dysfunction.

Elderly:

No overall difference in safety and effectiveness compared with younger patients. ■ See Dose Adjustments. ■ There is a major decrease in plasma clearance of epirubicin in elderly female patients; monitor closely for signs of toxicity. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

May increase bone marrow and GI toxicity of other **chemotherapeutic agents.** ■ Increased toxicity including skin redness and exfoliative changes possible when given concurrently with or after **radiation.** ■ Monitoring of cardiac function may be indicated in patients taking **medications that may cause heart failure** (e.g., calcium channel blockers such as verapamil), beta-blockers (e.g., propranolol). ■ Plasma clearance decreased and serum levels increased by **cimetidine**; discontinue cimetidine. ■ Epirubicin is extensively metabolized in the liver; **changes in hepatic function induced by concomitant therapies** may affect epirubicin metabolism, pharmacokinetics, effectiveness, and toxicity. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin, idarubicin) **and/or radiation encompassing the heart.** ■ **Trastuzumab** may persist in circulation for up to 7 months. Avoid anthracycline-based therapy for up to 7 months after stopping trastuzumab when possible. Monitor cardiac function closely if anthracyclines are used before this time**.** ■ Risk of cardiotoxicity is also increased when epirubicin is administered with **other cardiotoxic agents;** if possible, delay epirubicin-based therapy until other cardiotoxic agents have been cleared from the circulation. Careful cardiac monitoring is required if delay is not feasible. ■ Concomitant administration with other cytotoxic drugs may produce additive toxicity, especially hematologic and GI effects. ■ Leukopenic and/or thrombocytopenic effects may be increased with **drugs that cause blood dyscrasias** (e.g., anticonvulsants [e.g., carbamazepine, phenytoin], NSAIDs [e.g., ibuprofen, naproxen]). ■ Administration of epirubicin immediately before or after **paclitaxel** increased the systemic exposure (AUC) of epirubicin. The mean AUC of epirubicin's metabolites increased when paclitaxel was administered immediately after epirubicin. Epirubicin had no effect on the exposure of paclitaxel. ■ Administration of epirubicin immediately before or after **docetaxel** had no effect on the systemic exposure of epirubicin. However, the mean AUC of epirubicin's metabolites increased when docetaxel was administered immediately after epirubicin. Epirubicin had no effect on the AUC of docetaxel. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents. Killed or inactivated vaccines may be administered; however, the response to these vaccines may be diminished. ■ See Precautions.

SIDE EFFECTS

Acute adverse events occurring in 10% or more of patients included alopecia, amenorrhea, conjunctivitis/keratitis, diarrhea, hematologic toxicity (anemia, leukopenia, neutropenia, thrombocytopenia), infection, lethargy, local toxicity, mucositis, nausea/vomiting, and rash/itch. Dose-limiting toxicities are infection, myelosuppression, and cardiotoxicity (usually delayed, manifested by reduced LVEF and/or S/S of CHF [e.g., ascites, dependent edema, dyspnea, gallop rhythm, hepatomegaly, pleural effusion, pulmonary edema, tachycardia]). Other serious cardiovascular adverse reactions that have occurred include AV block, bradycardia, bundle branch block, thromboembolism, and ventricular tachycardia. Severe cellulitis, vesication, local pain, and tissue necrosis can occur with extravasation. Venous sclerosis may result from injection into small veins or repeated injection into the same vein. Other side effects are anorexia, febrile neutropenia, fever, hot flashes, malaise, mucositis (esophagitis, stomatitis), phlebitis, recall of skin reaction associated with prior radiation. Hypersensitivity reactions have been reported.

Overdose:

May cause an acute myocardial dysfunction within 24 hours. Bone marrow aplasia, gastrointestinal bleeding, Grade 4 mucositis, hyperthermia, lactic acidosis, multiple organ failure, and death have been reported following significant overdoses.

Post-Marketing:

Anaphylaxis; chills; dehydration; erythema; fever; flushing; GI disorders (e.g., bleeding, burning, pain, ulceration); hyperpigmentation of the skin, nails, and oral mucosa; hyperuricemia; photosensitivity; pneumonia; pulmonary embolism; radiation recall; red coloration of urine for 1 to 2 days; sepsis; urticaria; and vascular disorders (arterial embolism, hemorrhage, phlebitis, shock, and thrombophlebitis).

ANTIDOTE

Most side effects will either be tolerated or treated symptomatically. Keep the physician informed. Discontinue in patients who develop S/S of cardiomyopathy. Hematopoietic toxicity (leukopenia, thrombocytopenia) may require dose reduction or cessation of therapy, antibiotics, platelet and granulocyte transfusions, darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, or sargramostim. Acute cardiac failure occurs suddenly (most common when total cumulative doses approach 900 mg/M^2) and frequently does not respond to currently available treatment. Close monitoring of accumulated dose, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal cardiac side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Dexrazoxane is currently available to prevent cardiotoxicity of doxorubicin in specific situations; in the future it may be considered with epirubicin. If extravasation occurs, discontinue immediately, and attempt aspiration of the infiltrated epirubicin. Elevate the extremity and apply local intermittent ice compresses for up to 3 days. If appropriate, administer dexrazoxane (Totect) at the site of extravasation as soon as possible and within the first 6 hours after extravasation. Observe the site frequently. Should be seen by a reconstructive surgeon if local pain persists or skin changes progress after 3 to 4 days. Ulceration may require early wide excision of the involved area and skin grafting. Treat hypersensitivity reactions as indicated.

EPOETIN ALFA BBW ■ EPOETIN ALFA-epbx[a] BBW

(ee-**POH**-ee-tin **AL**-fah)

EPO, Epogen, Erythropoietin, Procrit, Retacrit[a]
Recombinant human erythropoietin
Erythropoiesis-stimulating agent (ESA) Hematopoietic agent
pH 5.8 to 7.2

USUAL DOSE

Epoetin alfa-epbx[a] **is a biosimilar drug of epoetin alfa (Epogen, Procrit). Unless specifically stated otherwise, information in this monograph applies**

to all formulations of epoetin-alfa.

Pretreatment:

In all situations, rate of hematocrit increase is dose dependent and varies among patients. Availability of iron stores, baseline hematocrit, and concurrent medical problems affect the rate and extent of response. Correct or exclude other causes of anemia (e.g., vitamin deficiency, metabolic or chronic inflammatory conditions, bleeding) before initiating epoetin alfa. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see Precautions and Monitor.

Anemia associated with chronic kidney disease (CKD) for patients on dialysis:

Initiate epoetin when the hemoglobin level is less than 10 Gm/dL. ***Starting dose:*** 50 to 100 units/kg of body weight three times a week. May be given by IV or SC injection or into the venous line at the end of a dialysis session. The IV route is recommended in patients on hemodialysis; see Precautions.

Anemia associated with chronic kidney disease (CKD) for patients NOT on dialysis:

Consider initiating epoetin only when the hemoglobin level is less than 10 Gm/dL and the following two considerations apply: (1) the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion, and (2) reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal. ***Starting dose:*** 50 to 100 units/kg of body weight three times a week.

Anemia in zidovudine-treated, HIV-infected patients:

May be given IV or SC. 100 units/kg 3 times a week. Obtain endogenous serum erythropoietin level (before transfusion) before initiating therapy; see Monitor. Serum erythropoietin levels in adults should be equal to or less than 500 mUnits/mL, and the zidovudine dose should be equal to or less than 4,200 mg/week.

Anemia associated with cancer patients on chemotherapy:

SC injection recommended. ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with certain types of cancer; see Precautions. Initiate epoetin in patients on cancer chemotherapy only if the hemoglobin is less than 10 Gm/dL and there is a minimum of 2 additional months of planned chemotherapy. Use the lowest dose necessary to avoid RBC transfusions. ***Starting dose:*** 150 units/kg of body weight 3 times a week until completion of chemotherapy course. An alternative schedule is 40,000 units weekly until completion of chemotherapy course.

Reduction of allogeneic blood transfusions in surgery patients:

SC injection recommended. Obtain hemoglobin before initiating therapy. Should be greater than 10 Gm/dL but less than or equal to 13 Gm/dL. 300 units/kg/day for 10 days before surgery, on the day of surgery, and for 4 days after surgery. An alternate regimen is 600 units/kg once each week on Days 21, 14, and 7 before surgery and again on the day of surgery. Deep venous thrombosis prophylaxis is recommended during epoetin therapy (e.g., enoxaparin [Lovenox]); see Precautions.

PEDIATRIC DOSE

May be given by IV or SC injection. The IV route is recommended in patients on hemodialysis; see Precautions. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see Precautions and Monitor.

Anemia of CKD in pediatric patients 1 month to 16 years of age:

Initiate epoetin when the hemoglobin level is less than 10 Gm/dL. ***Starting dose:*** 50 units/kg of body weight 3 times a week. May be given into the venous line at the end of the dialysis session.

Anemia in zidovudine-treated, HIV-infected pediatric patients 8 months to 17 years (unlabeled):

Doses of 50 to 400 units/kg 2 to 3 times a week have been reported. See all comments under the similar section in Usual Dose. Adjust dose to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion; see Dose Adjustments.

Anemia associated with pediatric cancer patients on chemotherapy, ages 5 to 18 years:

See comments under Usual Dose. ***Starting dose:*** 600 units/kg IV weekly until completion of chemotherapy course. Do not exceed 40,000 units.

DOSE ADJUSTMENTS

Dose adjustment is based on hemoglobin. Adjust dose to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion.

All adult and pediatric patients with CKD:

When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. Dose should be started slowly and adjusted for each patient to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion. Allow sufficient time before adjusting a dose; increased hemoglobin levels may not be observed for 2 to 6 weeks. ■ Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period), reduce the dose by 25% or more as needed to reduce rapid responses. ■ For patients who do not respond adequately after 4 weeks of therapy (e.g., the hemoglobin has not increased by more than 1 Gm/dL), increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase risks. Discontinue epoetin if responsiveness does not improve.

Adult patients with CKD on dialysis:

If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of epoetin.

Adult patients with CKD NOT on dialysis:

If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of epoetin.

Pediatric patients with CKD:

If the hemoglobin level approaches or exceeds 12 Gm/dL, reduce or interrupt the dose of epoetin.

Zidovudine-treated, HIV-infected patients and cancer patients on chemotherapy:

If hemoglobin does not increase after 8 weeks of therapy, increase dose by 50 to 100 units/kg. May increase dose at 4- to 8-week intervals until hemoglobin reaches a level needed to avoid RBC transfusions or dose reaches 300 units/kg. ■ Withhold dose if the hemoglobin exceeds 12 Gm/dL. Restart dose at 25% below previous dose when hemoglobin falls to less than 11 Gm/dL. ■ Discontinue epoetin if increase in hemoglobin is not achieved at a dose of 300 units/kg for 8 weeks.

Cancer patients on chemotherapy:

Reduce dose by 25% when the hemoglobin reaches a level needed to avoid transfusion or increases more than 1 Gm/dL in any 2-week period. ***Withhold dose*** if the hemoglobin exceeds a level needed to avoid transfusion, and restart at 25% below the previous dose when the hemoglobin approaches a level at which transfusions may be required. ■ Increase **adult dose** to 300 units/kg three times a week or 60,000 units weekly if hemoglobin increases by less than 1 Gm/dL and remains below 10 Gm/dL after the initial 4 weeks of therapy. Increase **pediatric dose** to 900 units/kg weekly if hemoglobin increases by less than 1 Gm/dL and remains below 10 Gm/dL after the initial 4 weeks of therapy. Do not exceed a dose of 60,000 units. ■ Discontinue epoetin after 8 weeks if no response as measured by hemoglobin levels or by continued need for RBC transfusions.

DILUTION

Available as a clear, colorless solution in numerous concentrations from 2,000 units /mL to 40,000 units/mL; check dose on vial carefully. May be given undiluted as an IV injection. Do not dilute (see exception below). ***Do not shake*** during preparation; will render it biologically inactive. Single-dose vial contains no preservatives. Use only 1 dose per vial, then discard. Never re-enter a preservative-free vial. Epogen and Procrit are available in a multidose vial with preservative (benzyl alcohol); sterile technique imperative. Do not use vials that have been shaken or frozen. Epogen and Procrit single-dose preservative-free vials may be admixed in a syringe with bacteriostatic NS in a 1:1 ratio at the time of administration except when administered to pregnant or lactating women, neonates, or infants.

Storage:

Store all vials in refrigerator at 2° to 8° C (36° to 46° F) in original carton to protect from light. Refrigerate multiple-dose vial after initial use. Discard multiple-dose vial 21 days after initial entry. Do not freeze or shake any vial of epoetin-alfa.

Filters:

Specific information not available for all formulations.

COMPATIBILITY

Manufacturers state, "Do not dilute or administer in conjunction with other drug solutions." One source indicates there may be protein loss from adsorption to PVC containers and tubing. Manufacturer suggests it may be mixed 1-to-1 with bacteriostatic NS in a syringe when prepared from a single-dose vial.

RATE OF ADMINISTRATION

A single dose over at least 1 minute.

ACTIONS

An amino acid glycoprotein manufactured by recombinant DNA technology. Has the same biologic effects as erythropoietin produced naturally by the kidneys. Stimulates bone marrow to produce RBCs, increasing the reticulocyte count within 10 days and the red cell count, hemoglobin, and hematocrit within 2 to 6 weeks. Normal iron stores are necessary because it steps up RBC production to a rate above what the body usually makes. New cells need iron, which is quickly depleted. Half-life is 4 to 13 hours. Continued therapy will maintain improved RBC levels and decrease need for transfusions.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease in adults and pediatric patients, including patients on dialysis and not on dialysis, to decrease the need for red blood cell (RBC) transfusion. ■ Treatment of anemias related to zidovudine (AZT, Retrovir) therapy in HIV-infected patients. ■ To reduce the need for allogeneic blood transfusions among patients with perioperative hemoglobin greater than 10 to less than or equal to 13 Gm/dL who are at high risk for perioperative blood loss from elective, noncardiac, nonvascular surgery. ■ Treatment of chemotherapy-induced anemia in adult cancer patients who have nonmyeloid malignancies in which anemia is due to the effect of concomitant myelosuppressive chemotherapy and who, upon initiation of therapy, have a minimum of 2 additional months of planned chemotherapy.

Limitations of use:

Not indicated for use in patients receiving hormonal agents, therapeutic biologic products, or radiotherapy unless receiving concomitant myelosuppressive chemotherapy. ■ Not indicated for patients receiving myelosuppressive therapy when the anticipated outcome is cure; see Precautions. ■ Not indicated for patients with cancer who are receiving myelosuppressive chemotherapy and in whom the anemia can be managed by transfusion. ■ Has not been shown to improve quality of life, fatigue, or patient well-being. ■ Not indicated in patients scheduled for surgery who are willing to donate autologous blood. ■ Not indicated in patients undergoing cardiac or vascular surgery. ■ Not indicated as a substitute for a RBC transfusion in patients who require immediate correction of anemia.

Unlabeled uses:

Anemia of prematurity.

CONTRAINDICATIONS

Known hypersensitivity to epoetin alfa, uncontrolled hypertension, pure red cell aplasia (PRCA). Epoetin alfa from multidose vials containing benzyl alcohol is contraindicated in neonates, infants, pregnant women, and nursing mothers.

PRECAUTIONS

May be given IV or SC in patients not receiving dialysis. May be given to dialysis patients into the venous line at the end of the dialysis procedure to eliminate additional venous access. ■ Erythropoiesis-stimulating agents (ESAs) increase the risk of death, MI, stroke, congestive heart failure, and thrombosis of hemodialysis vascular access and other thromboembolic events. ■ In clinical trials of patients with CKD, patients experienced greater risks of these adverse events when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, an epoetin alfa dose, or a dosing strategy that does not increase these risks. Use the lowest epoetin alfa dose sufficient to reduce the need for RBC transfusions. Providers and patients should weigh the possible benefits of decreasing transfusions against the increased risks of death and other serious cardiovascular adverse reactions. ■ Use with caution in patients with coexistent cardiovascular disease and stroke. Patients with CKD who have an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ In clinical trials, ESAs increased the risk of death in patients undergoing CABG surgery and the risk of deep venous thrombosis in patients undergoing orthopedic procedures. ■ Increases in hemoglobin of greater than 1 Gm/dL during any 2-week period have been associated with an increased incidence of cardiac arrest, exacerbations of hypertension, congestive heart failure (CHF), vascular thrombosis/ischemia/infarction, acute MI, deep vein thrombosis (DVT), pulmonary embolus, and fluid overload/edema and may be associated with neurologic events (e.g., seizures, stroke). See Dose Adjustments. ■ For lack or loss of hemoglobin response to epoetin alfa, initiate a search for causative factors (e.g., bleeding, infection, inflammation, iron deficiency). If typical causes of lack or loss of hemoglobin response are excluded, evaluate for pure red cell aplasia (PRCA). In the absence of PRCA, follow dosing recommendations for management of patients with an insufficient hemoglobin response to epoetin alfa therapy. ■ Not intended for use in anemias caused by iron or folate deficiencies, hemolysis, or GI bleeding or for use in treating symptoms of anemia, including dizziness, fatigue, low energy, poor quality of life, or shortness of breath. ■ PRCA and severe anemia, with or without other cytopenias, in association with neutralizing antibodies to native erythropoietin have been observed. Most often reported in patients with CKD who are receiving epoetin alfa by SC injection. Any patient who develops a sudden loss of response to epoetin alfa accompanied by severe anemia and low reticulocyte count should be evaluated. Physicians may contact manufacturer (Amgen) for help with the evaluation of these patients. ■ Administration of erythropoiesis-stimulating agents (ESAs) to cancer patients shortened the overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of some patients with breast, cervical, head and neck, lymphoid, and non–small-cell lung malignancies; see prescribing information for specific studies. To minimize these risks, as well as the risks of serious cardiovascular and thromboembolic events, use the lowest dose needed to avoid a red blood cell transfusion. Use only to treat anemia due to concomitant myelosuppressive chemotherapy, and discontinue after completion of a chemotherapy course. ■ BP may increase during therapy with epoetin. Hypertensive encephalopathy and seizures have been observed. ■ Patients with uncontrolled hypertension should not be treated with epoetin until BP has been adequately controlled. ■ Epoetin increases the risk of seizures in patients with CKD. Use with caution in patients with a seizure disorder. ■ Serious hypersensitivity reactions, including anaphylaxis, have been reported. ■ Blistering and skin exfoliation reactions, including erythema multiforme and Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN), have been reported. ■ Epogen and Procrit contain albumin and carry a risk for transmission of viral diseases or Creutzfeldt-Jakob disease. However, donor screening and manufacturing processes make this risk extremely remote. ■ Retacrit contains 0.5 mg of phenylalanine in each 1-mL single-dose vial (all concentrations) and may be harmful to patients with phenylketonuria (PKU). Consider combined daily amount of phenylalanine from all sources before prescribing Retacrit.

Monitor:

Monitor hemoglobin weekly in patients who are initiating therapy. Continue until stable and the maintenance dose has been established, then monitor at least monthly. ■ Monitor hemoglobin weekly for at least 4 weeks following adjustment of therapy. Once stabilized, continue to monitor at least monthly. ■ A biologic product. Monitor for S/S of hypersensitivity reactions. ■ Monitor BP routinely; initiation or intensification of antihypertensive therapy and dietary restrictions may be necessary. If BP is difficult to control by pharmacologic or dietary measures, the dose of epoetin should be reduced or withheld. ■ Normal iron stores required to support epoetin-stimulated erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 ng/mL. Monitor before and during therapy. Supplemental iron is usually required to increase and maintain transferrin saturation. Administration of IV parenteral iron may be necessary in some patients. ■ Monitor for the presence of premonitory neurologic symptoms during initiation of therapy or when dose is adjusted. Seizures have been reported; see Precautions. ■ Monitor patients with pre-existing vascular disease carefully (especially those with CKD); increase in hematocrit may precipitate a cerebrovascular accident, transient ischemic attack, or myocardial infarction. ■ Dialysis patients may require additional anticoagulation with heparin to prevent clotting of artificial kidney or clotting of the vascular access (AV shunt) and to maintain efficiency of the dialysis procedure.

Patient Education:

Risk of seizures, especially during first 90 days of therapy. Contact provider for new-onset seizures, premonitory symptoms, or a change in seizure frequency. ■ Additional instruction (e.g., equipment, techniques) will be required in patients who will self-administer (manufacturer supplies brochure). ■ Stress importance of compliance with diet, iron, and vitamin (e.g., folic acid, B_{12}) supplementation and BP control. Close monitoring of BP and Hgb is imperative. ■ Promptly report S/S of hypersensitivity or skin reactions, pain or swelling in legs, SOB, increase in BP, dizziness, or loss of consciousness. ■ Increased risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression or recurrence. ■ Read Medication Guide carefully. All patients should discuss the risks of using an ESA with a health care professional.

Maternal/Child:

May present risk to fetus; benefits must justify risk. ■ Some formulations contain benzyl alcohol. Serious and fatal reactions, including "gasping syndrome," can occur in neonates and infants treated with drugs preserved in benzyl alcohol. There is a potential for similar risks to fetuses and infants exposed to benzyl alcohol in utero or in breast-fed milk, respectively; see Contraindications. ■ Use caution in nursing mothers. ■ Indicated in pediatric patients ages 1 month to 16 years of age for the treatment of anemia associated with CKD requiring dialysis. Use of epoetin alfa in pediatric patients with CKD not requiring dialysis is supported by efficacy in pediatric patients requiring dialysis. ■ Safety and effectiveness for use in infants under 1 month of age not established. ■ Indicated in pediatric cancer patients ages 5 to 18 years for the treatment of anemia due to myelosuppressive chemotherapy. ■ Has been used in zidovudine-treated and anemic pediatric patients ages 8 months to 17 years. Data limited. ■ Pharmacokinetics (absorption, distribution, metabolism, and excretion) in children and adolescents similar to adults. ■ Limited data available for use in neonates. Clearance may be increased compared to adults.

Elderly:

Epogen and Procrit: Response similar to that found in younger patients; however, elderly patients may have a greater sensitivity to its effects. ***Retacrit:*** Response unknown due to insufficient numbers in studies.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Generally well tolerated. Occur most frequently in patients with chronic renal failure. Increased hypertension is common, and hypertensive encephalopathy and seizures can occur. Clotted vascular access (AV shunt) and clotting of the artificial kidney may occur during dialysis. Allergic reactions have been reported. Other reported side effects are those common to the underlying disease and not necessarily attributable to epoetin and include arthralgias, asthenia, bone marrow fibrosis, bone pain, cerebrovascular accident or transient ischemic attack (CVA/TIA), chest pain, chills, cough, deep vein thrombosis, depression, diarrhea, dizziness, dysphagia, edema, fatigue, fever, headache, hyperglycemia, hyperkalemia, hypokalemia, injection site irritation or pain, insomnia, muscle spasm, myocardial infarction, nausea, polycythemia, pruritus, rash, respiratory congestion, shortness of breath, stomatitis, tachycardia, upper respiratory tract infection, vomiting, and weight decrease. PRCA and severe anemia, with or without other cytopenias, in association with neutralizing antibodies have been reported; see Precautions.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of epoetin until BP is controlled or may respond to reduction in dose of epoetin or to an increase in antihypertensive therapy. Reduce dose of epoetin in patients with an increase in hemoglobin over 1 Gm/dL in any 2-week period. Consider phlebotomy in toxicity. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Additional heparin may be required during dialysis to prevent clotting. Permanently discontinue therapy in patients with antibody-mediated anemia or severe cutaneous reactions. Patients should not be switched to other erythropoietic proteins because antibodies may cross-react. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

EPOPROSTENOL SODIUM

(eh-poh-**PROST**-en-ohl **SO**-dee-um)
Flolan, Veletri
Prostaglandin
Vasodilating agent
Antihypertensive (pulmonary)
pH 10.2 to 13

USUAL DOSE

Acute dose initiation and chronic continuous infusion:

May be given through a peripheral line on a temporary basis until a central venous line is established. A central venous catheter should be put in place as soon as possible and must be used for continuous long-term 24-hour administration with an ambulatory infusion pump. Begin infusion at 2 ng/kg/min. Increase in increments of 1 to 2 ng/kg/min every 15 minutes or longer until dose-limiting pharmacologic effects occur or until a tolerance limit to the drug is established and further increases in the infusion rate are not clinically warranted; see Dose Adjustments. Most common S/S of dose-limiting effects include abdominal pain, flushing, headache, hypotension, nausea, respiratory disorders, sepsis, and vomiting. If dose-limiting pharmacologic effects occur, decrease infusion rate slowly until pharmacologic effects are tolerated; see Dose Adjustments. If the initial dose of 2 ng/kg/min is not tolerated, use a lower dose. May be given concomitantly with anticoagulant therapy in selected patients; see Monitor.

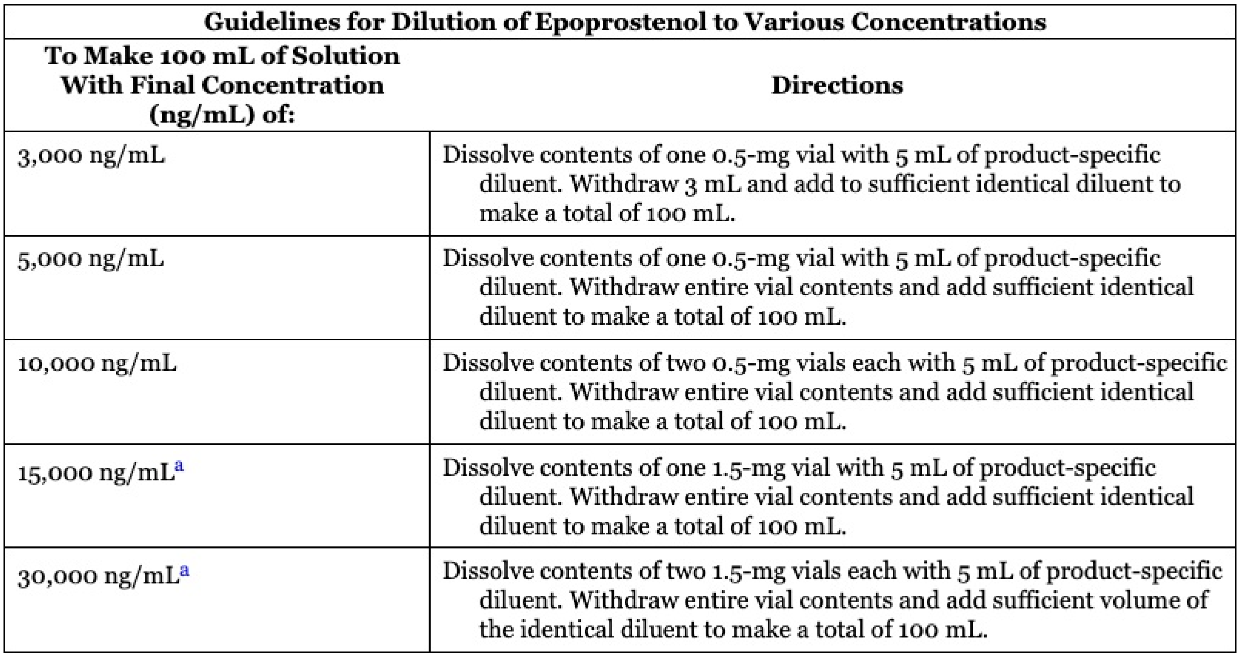
DOSE ADJUSTMENTS

Changes in the chronic infusion rate are to be expected. If symptoms of primary pulmonary hypertension (PPH) persist, recur, or worsen, increase infusion rate promptly by 1 to 2 ng/kg/min. Wait at least 15 minutes to assess clinical response. Observe patient for several hours to confirm patient tolerance, and take BP and HR in supine and standing positions. ■ Occurrence of dose-related side effects that do not resolve may require a decrease in the chronic infusion rate. Reduce dose gradually in 2-ng/kg/min increments and wait at least 15 minutes to assess clinical response. Use extreme caution if decreasing the dose; abrupt withdrawal or sudden large reductions may cause a rapid return of PPH symptoms and may precipitate death. ■ In patients receiving lung transplants, doses were tapered after the initiation of cardiopulmonary bypass. ■ Dose selection for the elderly should be cautious. ■ Asymptomatic increases in pulmonary artery pressure with increases in cardiac output may occur during acute dose initiation; consider dose adjustment. ■ See Precautions.

DILUTION

Infusion pump required. It must be small and lightweight; able to adjust infusion rates in increments of 2 ng/kg/min; have occlusion, end of infusion, and low battery alarms; be accurate to ±6% of the programmed rate; be positive-pressure driven (continuous or pulsatile) with intervals between pulses not exceeding 3 minutes at rates required to deliver drug; and have a disposable reservoir cassette made of polyvinyl chloride, polypropylene, or glass with a capacity of at least 100 mL. Pumps used during trials were manufactured by Pharmacia Deltec, Medfusion, Inc., and Baxter Health Care. The infusion pump used in the most recent clinical trials was the CADD-1 HFX 5100 (SIMS Deltec). A 60-inch microbore non-DEHP extension set with proximal antisiphon valve, low priming volume (0.9 mL), and in-line 0.22-micron filter was used during clinical trials. Preparation and administration materials containing polyethylene terephthalate (PET) or polyethylene terephthalate glycol (PETG) may become damaged when used with **Flolan prepared with pH 12 sterile diluent for Flolan** and therefore must not be used.

Available in 0.5- and 1.5-mg single-dose vials. The diluents specified for each product are to be used for reconstitution and dilution. ***Flolan:*** Sterile diluent for Flolan or pH 12 sterile diluent for Flolan is provided by the manufacturer. Do not use any other diluent. ***Generic:*** Sterile diluent for epoprostenol is provided by the manufacturer. Do not use any other diluent. ***Veletri:*** Reconstitute and dilute with SWFI or NS (not provided by manufacturer). A concentration should be selected that is **compatible** with the infusion pump being used with respect to minimum and maximum flow rates, reservoir capacity, and the infusion pump criteria. See Rate of Administration. Two vials of the manufacturer-supplied sterile diluent for ***Flolan and generic*** will be required to prepare each 24-hour dose in each of the concentrations in the following chart.



Guidelines for Dilution of Epoprostenol to Various Concentrations	
To Make 100 mL of Solution With Final Concentration (ng/mL) of:	**Directions**
3,000 ng/mL	Dissolve contents of one 0.5-mg vial with 5 mL of product-specific diluent. Withdraw 3 mL and add to sufficient identical diluent to make a total of 100 mL.
5,000 ng/mL	Dissolve contents of one 0.5-mg vial with 5 mL of product-specific diluent. Withdraw entire vial contents and add sufficient identical diluent to make a total of 100 mL.
10,000 ng/mL	Dissolve contents of two 0.5-mg vials each with 5 mL of product-specific diluent. Withdraw entire vial contents and add sufficient identical diluent to make a total of 100 mL.
15,000 ng/mL[a]	Dissolve contents of one 1.5-mg vial with 5 mL of product-specific diluent. Withdraw entire vial contents and add sufficient identical diluent to make a total of 100 mL.
30,000 ng/mL[a]	Dissolve contents of two 1.5-mg vials each with 5 mL of product-specific diluent. Withdraw entire vial contents and add sufficient volume of the identical diluent to make a total of 100 mL.

[a] Higher concentrations may be prepared for patients who receive epoprostenol long-term.

Prepare in a drug delivery reservoir appropriate for the infusion pump with a total reservoir volume of at least 100 mL. In general, 3,000 ng/mL and 10,000 ng/mL concentrations should be satisfactory to deliver between 2 and 16 ng/kg/min in adults.

Filters:

An in-line 0.22-micron filter was used during clinical trials.

Storage:

All products: Vials are for single use only; discard any unused diluent or unused reconstituted solution. ***Flolan and generic:*** Unopened vials of epoprostenol may be stored at 15° to 25° C (59° to 77° F [***generic*** at CRT]) in the carton to protect from light. Diluent may be stored at 15° to 25° C (59° to 77° F [***generic*** at CRT]). Protection from light not required. Do not freeze. See expiration dates on both. ***Flolan and generic diluted with sterile diluent:*** When used at room temperature, reconstituted solutions are stable for up to 8 hours following reconstitution or removal from refrigeration and may be stored for up to 40 hours before use if refrigerated. When used with a cold pack, reconstituted solutions are stable for up to 24 hours, or may be refrigerated before use as long as the total time of refrigerated storage and infusion does not exceed 48 hours. Change cold packs every 12 hours. Before use, reconstituted solutions ***(Flolan and generic)*** must be refrigerated and protected from light. Do not freeze. ***Flolan diluted with pH 12 sterile diluent:*** Freshly prepared reconstituted solutions or reconstituted solutions that have been refrigerated at 2° to 8° C (36° to 46° F) for no longer than 8 days can be administered from 12 to 72 hours at specific temperatures; see prescribing information. Protect from light and do not freeze.

Veletri:

Unopened vials may be stored at 20° to 25° C (68° to 77° F) in the carton to protect from direct sunlight. Vials reconstituted with 5 mL of SWFI or NS and further diluted with the identical diluent must be protected from light and can be refrigerated at 2° to 8° C (36° to 46° F) for as long as 8 days. Maximum duration of administration ranges from 24 to 72 hours and is dependent on ambient temperature, final concentration, and duration of refrigerated storage before administration; see Prescribing Information.

COMPATIBILITY

Manufacturer states, "Stable only when reconstituted with the provided or recommended diluent. Must not be reconstituted or mixed with any other parenteral medications or solutions prior to or during administration." Manufacturer states, "Preparation and administration materials containing polyethylene terephthalate (PET) or polyethylene terephthalate glycol (PETG) may become damaged when used with **Flolan prepared with pH 12 sterile diluent for Flolan** and therefore must not be used. Consult the manufacturer of the sets to confirm that they are considered **compatible** with highly alkaline solutions, such as Flolan prepared with pH 12 sterile diluent for Flolan."

One source suggests **compatibility** at the **Y-site** with bivalirudin (Angiomax).

RATE OF ADMINISTRATION

Administered by a continuous IV infusion through a central venous catheter using an ambulatory infusion pump. Peripheral access may be used temporarily until a central line can be placed. Do not administer bolus injections of epoprostenol. Titrate dose as outlined in Usual Dose and Dose Adjustments. If dose-limiting pharmacologic effects occur, decrease infusion rate slowly until pharmacologic effects are tolerated; see Dose Adjustments. The infusion rate may be calculated using the following formula:

$$\text{Infusion rate (mL/hr)} = \frac{\text{Dose (ng/kg/min)} \times \text{Weight in kg} \times \text{60 min/hr}}{\text{Final concentration (ng/mL)}}$$

Example calculations for infusion rates are as follows:

Example 1: For a 60-kg person at the recommended initial dose of 2 ng/kg/min using a 3,000 ng/mL concentration, the infusion rate would be as follows:

$$\text{Infusion rate (mL/hr)} = \frac{[2\ \text{(ng/kg/min)} \times 60\ \text{(kg)} \times 60\ \text{min/hr}]}{3{,}000\ \text{(ng/mL)}} = 2.4\ \text{(mL/hr)}$$

Example 2: For a 70-kg person at a dose of 16 ng/kg/min using a 15,000 ng/mL concentration, the infusion rate would be as follows:

$$\text{Infusion rate (mL/hr)} = \frac{[16\ \text{(ng/kg/min)} \times 70\ \text{(kg)} \times 60\ \text{min/hr}]}{15{,}000\ \text{(ng/mL)}} = 4.48\ \text{(mL/hr)}$$

ACTIONS

A naturally occurring prostaglandin. It directly vasodilates pulmonary and systemic arterial vascular beds and inhibits platelet aggregation. Produces dose-related increases in cardiac index and stroke volume and dose-related decreases in pulmonary vascular resistance, total pulmonary resistance, and mean systemic arterial pressure. Has been shown to increase exercise capacity, improve hemodynamic status, and extend survival. Onset of action is immediate. Half-life is approximately 6 minutes at body pH of 7.4. Rapidly hydrolyzed and is also subject to enzymatic degradation. Excreted in urine and feces.

INDICATIONS AND USES

Treatment of pulmonary arterial hypertension (PAH [WHO Group 1]) to improve exercise capacity. Effectiveness established predominantly in patients with NYHA Functional Class III-IV symptoms and etiologies of idiopathic or heritable PAH or PAH associated with connective tissue diseases.

CONTRAINDICATIONS

Heart failure due to severe left ventricular systolic dysfunction. ■ Known hypersensitivity to epoprostenol, related compounds, or any component of the formulation. ■ Patients who develop pulmonary edema during dose initiation **(Veletri)**.

PRECAUTIONS

Administered by or under the direction of the physician specialist. ■ During dose initiation, facilities for monitoring the patient and responding to any medical emergency must be available. ■ Abrupt withdrawal, interruptions in drug delivery, or sudden large reductions in dose may result in rebound pulmonary hypertension. Symptoms may include dyspnea, dizziness, and weakness. Death of one patient was attributed to these causes. Backup medication and equipment must always be available. ■ Use of a multilumen catheter should be considered if other IV therapy is used. ■ Not recommended for patients who develop pulmonary edema during acute dose initiation. Consider the possibility of associated pulmonary veno-occlusive disease in these patients; see Contraindications. ■ Asymptomatic increases in pulmonary artery pressure with increases in cardiac output may occur during acute dose initiation; consider dose adjustment. ■ Cardiac catheterization may be used for acute dose initiation but is not necessary; consider benefit versus risk. ■ In patients undergoing lung transplants, it is recommended that the dose of epoprostenol be tapered after initiation of cardiopulmonary bypass. ■ A potent inhibitor of platelet aggregation; an increased risk for hemorrhagic complications may occur, particularly in patients with other risk factors for bleeding. ■ See Monitor, Patient Education, Drug/Lab Interactions.

Monitor:

Frequent monitoring of vital signs recommended during acute dose initiation. ■ Monitor standing and supine HR and BP for several hours after any dose adjustment. ■ Observe for dose-limiting side effects (e.g., abdominal pain, dizziness, flushing, headache, hypotension, nausea, respiratory disorder, sepsis, vomiting). ■ Monitor for S/S of hemorrhagic complications. ■ To reduce the risk of pulmonary thromboembolism or systemic embolism through a patent foramen ovale, anticoagulant therapy is recommended concomitantly unless contraindicated. ■ Therapy may be required for months or years; consideration must be given to the ability of the patient and family to manage this care. ■ Thorough patient teaching and continued support services are imperative to facilitate a good clinical outcome. ■ See Precautions, Patient Education, Drug/Lab Interactions.

Patient Education:

After initial dose titration and training, this is a self-administered drug. Must assume responsibility for drug reconstitution, drug administration, and care of the permanent central venous catheter. Follow all dilution and storage requirements for the product that is being used. ■ Aseptic technique during reconstitution and with routine care of permanent indwelling central venous catheter is imperative to prevent infection. ■ Report fever or any sign of infection at catheter site (e.g., redness, warmth). ■ Report any unusual bruising or bleeding. ■ Delivery of medication cannot be interrupted. Interruption will cause a rapid return of PPH symptoms. ■ Should have access to a backup infusion pump and intravenous infusion sets to avoid potential interruption in drug delivery. ■ Dose adjustments should be made only under the direction of the physician except in an emergency situation (e.g., unconsciousness, collapse).

Maternal/Child:

Category B: ***(Veletri)***. ***All formulations:*** use only if clearly needed. No evidence of fetal harm in animal studies to date. Pregnant women with untreated PAH are at risk for heart failure, stroke, preterm delivery, and maternal and fetal death. Consider risk versus benefit. ■ Use during labor and delivery has not been adequately studied. ■ Use caution in nursing mothers; safety not established. ■ Safety for use in pediatric patients not established.

Elderly:

See Dose Adjustments. Decreased organ function (cardiac, hepatic, renal), concomitant disease, and other drug therapy may cause concern. Differences in response of younger patients versus the elderly not documented.

DRUG/LAB INTERACTIONS

Has been used with digoxin, diuretics, anticoagulants, oral vasodilators, and oxygen. ■ Hypotension may be increased with **diuretics, antihypertensive agents, or other vasodilators.** ■ Risk of bleeding may be increased with **antiplatelet agents, anticoagulants, or NSAIDs**. ■ May decrease clearance of **furosemide** and **digoxin;** monitor digoxin levels.

SIDE EFFECTS

Acute dose initiation:

The most common S/S of dose-limiting effects include flushing, headache, hypotension, nausea, and vomiting. Abdominal pain, agitation, anorexia, anxiety/nervousness, back pain, bradycardia, chest pain, dizziness, dyspepsia, dyspnea, hyperesthesia, hyperkinesias, musculoskeletal pain, myalgia, paresthesia, respiratory disorders, sepsis, sweating, tachycardia, tremor, urticaria, and many other side effects may occur.

Chronic continuous infusion:

Any of the above and arthralgia, bleeding at various sites, chills, diarrhea, fever, flu-like symptoms, infection (may be local at site of catheter insertion), jaw pain, pallor, pulmonary edema, rash, sepsis, thrombocytopenia.

Overdose:

Hypotension, hypoxemia, respiratory arrest, and death may occur.

Post-Marketing:

Anemia, hepatic failure, high-output cardiac failure, hypersplenism, hyperthyroidism, pancytopenia, pulmonary embolism, splenomegaly, thrombocytopenia.

ANTIDOTE

Continuous maintenance of drug flow imperative. Keep physician informed of all side effects. Most will be treated with dose reduction; some may require symptomatic treatment. Discontinue therapy if pulmonary edema develops.

EPTIFIBATIDE

(**ep**-tih-**FY**-beh-tide)
Integrilin
Antiplatelet agent
pH 5.35

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Used in combination with heparin and aspirin. A calculated CrCl greater than or equal to 50 mL/min is required in patients receiving the following doses. Use of the Cockroft-Gault equation is recommended for calculating CrCl. Discontinue eptifibatide infusion before CABG surgery and in patients requiring thrombolytic therapy.

Acute Coronary Syndrome

Eptifibatide:

180 mcg/kg as an IV bolus as soon as possible following diagnosis. Follow with a continuous infusion of 2 mcg/kg/min until hospital discharge or initiation of coronary artery bypass graft (CABG) surgery for up to 72 hours. Alternately, if a patient is to undergo a percutaneous coronary intervention (PCI) while receiving eptifibatide, the infusion should be continued up to hospital discharge or for 18 to 24 hours after the

procedure, whichever comes first. Patient may receive up to 96 hours of therapy. See Dosing Chart by Weight on the following page and Dose Adjustments. Dose in patients with a calculated CrCl greater than or equal to 50 mL/min weighing more than 121 kg should not exceed a bolus of 22.6 mg or an infusion rate of 15 mg/hr.

Aspirin:

160 to 325 mg PO initially and daily thereafter.

Heparin:

Medical management: Suggested heparin dose to achieve the target aPTT of 50 to 70 seconds during medical management is ***Weight 70 kg or more,*** 5,000 units as an IV bolus followed by an infusion of 1,000 units/hr. ***Weight less than 70 kg,*** 60 units/kg as an IV bolus followed by an infusion of 12 units/kg/hr.

Patients undergoing PCI:

Target ACT is 200 to 300 seconds during PCI. If heparin is initiated before PCI, give additional boluses during PCI as needed to keep ACT in range. Heparin infusion after PCI is discouraged.

Percutaneous Coronary Intervention (PCI)

Eptifibatide:

180 mcg/kg as an IV bolus immediately before initiation of PCI followed by a continuous infusion of 2 mcg/kg/min. Repeat bolus of 180 mcg/kg 10 minutes after the first bolus. Continue infusion until hospital discharge or for up to 18 to 24 hours, whichever comes first. A minimum of 12 hours of infusion is recommended. See the following chart and Dose Adjustments. Dose in patients with a calculated CrCl greater than or equal to 50 mL/min weighing more than 121 kg should not exceed a bolus of 22.6 mg or an infusion rate of 15 mg/hr.

Aspirin:

160 to 325 mg PO 1 to 24 hours before PCI and daily thereafter.

Heparin:

Target ACT is 200 to 300 seconds during PCI. In patients not treated with heparin within 6 hours of PCI, give 60 units/kg as a bolus. Give additional boluses as needed during PCI to keep ACT in range. Heparin infusion is discouraged after PCI.

For Both Indications

Refer to the following Eptifibatide Dosing Chart by Weight.

Eptifibatide Dosing Chart by Weight

Patient Weight	180 mcg/kg Bolus Volume	2 mcg/kg/min Infusion Rate		1 mcg/kg/min Infusion Rate	
	From 2 mg/mL Vial	From 2 mg/mL 100-mL Vial	From 0.75 mg/mL 100-mL Vial	From 2 mg/mL 100-mL Vial	From 0.75 mg/mL 100-mL Vial
37–41 kg	3.4 mL	2 mL/hr	6 mL/hr	1 mL/hr	3 mL/hr
42–46 kg	4 mL	2.5 mL/hr	7 mL/hr	1.3 mL/hr	3.5 mL/hr
47–53 kg	4.5 mL	3 mL/hr	8 mL/hr	1.5 mL/hr	4 mL/hr
54–59 kg	5 mL	3.5 mL/hr	9 mL/hr	1.8 mL/hr	4.5 mL/hr
60–65 kg	5.6 mL	3.8 mL/hr	10 mL/hr	1.9 mL/hr	5 mL/hr
66–71 kg	6.2 mL	4 mL/hr	11 mL/hr	2 mL/hr	5.5 mL/hr
72–78 kg	6.8 mL	4.5 mL/hr	12 mL/hr	2.3 mL/hr	6 mL/hr
79–84 kg	7.3 mL	5 mL/hr	13 mL/hr	2.5 mL/hr	6.5 mL/hr
85–90 kg	7.9 mL	5.3 mL/hr	14 mL/hr	2.7 mL/hr	7 mL/hr
91–96 kg	8.5 mL	5.6 mL/hr	15 mL/hr	2.8 mL/hr	7.5 mL/hr
97–103 kg	9 mL	6 mL/hr	16 mL/hr	3 mL/hr	8 mL/hr
104–109 kg	9.5 mL	6.4 mL/hr	17 mL/hr	3.2 mL/hr	8.5 mL/hr
110–115 kg	10.2 mL	6.8 mL/hr	18 mL/hr	3.4 mL/hr	9 mL/hr
116–121 kg	10.7 mL	7 mL/hr	19 mL/hr	3.5 mL/hr	9.5 mL/hr
>121 kg	11.3 mL	7.5 mL/hr	20 mL/hr	3.7 mL/hr	10 mL/hr

DOSE ADJUSTMENTS

Acute Coronary Syndrome

In patients with a calculated CrCl less than 50 mL/min, give a bolus of 180 mcg/kg. Decrease rate of the continuous infusion to 1 mcg/kg/min. In patients with a calculated CrCl less than 50 mL/min or a SCr greater than 2 mg/dL and weighing more than 121 kg, a maximum bolus of 22.6 mg followed by a maximum infusion rate of 7.5 mg/hr should be administered.

PCI

In patients with a calculated CrCl less than 50 mL/min, give a bolus of 180 mcg/kg. Decrease rate of the continuous infusion to 1 mcg/kg/min. Repeat bolus of 180 mcg/kg 10 minutes after the first bolus. In patients with a calculated CrCl less than 50 mL/min or a SCr greater than 2 mg/dL and weighing more than 121 kg, a maximum bolus of 22.6 mg followed by a maximum infusion rate of 7.5 mg/hr should be administered.

All Diagnoses

Dose reduction may be indicated in patients over 75 years of age weighing less than 50 kg. ■ See Dosing Chart by Weight in Usual Dose. ■ See Contraindications.

DILUTION

The 10-mL vial contains 20 mg of eptifibatide; the 100-mL vials contain 75 mg or 200 mg of eptifibatide.

IV bolus:

Given undiluted. Withdraw total bolus dose (usually from the 10-mL vial) into a syringe.

Infusion:

Usually given undiluted directly from the 75 mg/100 mL (0.75 mg/mL) or the 200 mg/100 mL (2 mg/mL) vials using an IV infusion pump. The 100-mL vial should be spiked with a vented infusion set. Center the spike within the circle on the stopper top. May be diluted with NS or D5NS. Use of a metriset or infusion pump appropriate.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) or they may be kept at CRT for up to 2 months. Protect from light until administration. Do not use beyond the expiration or discard date. Discard any unused portion left in the vial.

COMPATIBILITY

Manufacturer lists furosemide as **incompatible** and states "is **incompatible** with any solution or drug not specifically listed as **compatible.**"

Manufacturer lists as **compatible** at **Y-site** with NS or D5NS with or without up to 60 mEq/L of potassium chloride as well as with alteplase, atropine sulfate, dobutamine, heparin, lidocaine, meperidine, metoprolol, midazolam, morphine, nitroglycerin IV, verapamil.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV bolus:

A single dose IV push over 1 to 2 minutes.

Infusion:

See Dosing Charts by Weight under Usual Dose.

ACTIONS

A cyclic heptapeptide (amino acid) that reversibly binds to the platelet receptor glycoprotein GP IIb/IIIa of human platelets and inhibits platelet aggregation by preventing the binding of fibrinogen, von Willebrand factor, and other adhesive ligands to GP IIb/IIIa. Inhibits platelet aggregation in a dose- and concentration-dependent manner. Recovery of platelet function after termination of the eptifibatide infusion is rapid. Administered alone, eptifibatide has no measurable effect on PT or aPTT. Does not exert a pharmacologic effect on other integrins. Recommended regimens of a bolus followed by an infusion produce immediate inhibition of platelet aggregation and an early peak level, followed by a small decline, with steady state achieved within 4 to 6 hours. This decline can be prevented by administering a second bolus. Plasma elimination half-life is approximately 2.5 hours. 50% cleared from plasma by the kidneys. Balance of clearance is by nonrenal mechanisms. Has been shown to reduce clinical events (e.g., acute MI, need for urgent intervention) in patients undergoing PCI during drug administration and in those receiving medical management alone.

INDICATIONS AND USES

Used in combination with heparin, aspirin and, in selected situations, a thienopyridine (e.g., clopidogrel, prasugrel). ■ Treatment of patients with acute coronary syndrome (unstable angina or non–ST-segment elevation MI), including those who are to be managed medically and those undergoing PCI. In this setting, has been shown to decrease the rate of a combined endpoint of death or new MI. ■ Treatment of patients undergoing PCI, including those undergoing intracoronary stenting. In this setting has been shown to decrease the rate of a combined endpoint of death, new MI, or need for urgent intervention.

CONTRAINDICATIONS

Known hypersensitivity to any component of the product. ■ Current or planned administration of another parenteral glycoprotein GPIIb/IIIa inhibitor (e.g., tirofiban). ■ Dependency on renal dialysis. ■ History of bleeding diathesis or evidence of active abnormal bleeding within the previous 30 days. ■ History of stroke within 30 days or any history of hemorrhagic stroke. ■ Major surgery within the preceding 6 weeks. ■ Severe hypertension (systolic BP greater than 200 mm Hg or diastolic BP greater than 110 mm Hg) not adequately controlled on antihypertensive therapy.

PRECAUTIONS

Use caution when given with drugs that affect hemostasis (e.g., NSAIDs, clopidogrel, dipyridamole, warfarin). Limited data on the use of eptifibatide in patients receiving thrombolytic agents (e.g., alteplase), reteplase, streptokinase) do not allow an estimate of the bleeding risk associated with concomitant use. Systemic thrombolytic therapy should be used with caution in patients who have received eptifibatide. See Drug/Lab Interactions. ■ Use with caution in patients with renal insufficiency; clearance is reduced and plasma levels are elevated; see Dose Adjustments. There is no experience in patients dependent on dialysis. ■ Bleeding is the most common complication encountered during therapy. ■ Risk of major bleeding increased inversely with patient weight, especially for patients weighing less than 70 kg. ■ Most major bleeding occurs at the arterial access site for cardiac catheterization or from the GI or GU tracts. ■ Acute profound thrombocytopenia has been reported; see Monitor. ■ Because eptifibatide is readily reversible, procedures such as emergency CABG may be performed safely shortly after discontinuation of an infusion without the need for platelet transfusions. ■ Development of antibodies to eptifibatide and immune-mediated thrombocytopenia have been reported; may be associated with hypotension and/or other signs of hypersensitivity. ■ No clinical experience in patients with a baseline platelet count less than 100,000/mm^3. Monitor closely if use is indicated.

Monitor:

Before therapy obtain platelet count, hemoglobin or hematocrit, SCr, and PT/aPTT. Obtain ACT in patients undergoing PCI. ■ Maintain target aPTT between 50 and 70 seconds unless PCI is to be performed. During PCI, the ACT should be maintained between 200 and 300 seconds. ■ The aPTT or ACT should be checked before sheath removal. The sheath should not be removed unless the aPTT is less than 45 seconds or the ACT is less than 150 seconds. In patients treated with heparin, bleeding can be minimized by close monitoring of the aPTT. ■ If acute profound thrombocytopenia occurs or the platelet count drops to less than 100,000/mm^3, heparin and eptifibatide should be discontinued. Monitor serial platelet counts, assess the presence of drug-dependent antibodies, and initiate appropriate therapy as indicated. ■ Monitor the patient for signs of bleeding; take vital signs (avoiding automatic BP cuffs); observe any invaded sites at least every 15 minutes (e.g., sheaths, IV sites, cutdowns, punctures, Foleys, NGs); watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, muscle weakness. Perform neuro checks frequently. If during therapy bleeding cannot be controlled with pressure, heparin and eptifibatide should be discontinued. ■ Use care in handling patient; minimize use of urinary catheters, nasotracheal intubation, and nasogastric tubes. Avoid arterial puncture, venipuncture, and IM injection. Use extreme precautionary methods and only compressible sites if these procedures are absolutely necessary (i.e., avoid subclavian or jugular veins). Apply pressure for 30 minutes to any invaded site and then apply pressure dressings. Saline or heparin locks suggested to facilitate blood draws. ■ See Precautions.

Additional monitoring for patients receiving PCI:

After PCI, eptifibatide should be continued until hospital discharge or for up to 18 to 24 hours, whichever comes first. See suggested time frames under each dose. Heparin use is discouraged after the PCI procedure. The femoral artery sheath may be removed during eptifibatide infusion, but only after heparin has been discontinued and its effects largely reversed. Heparin should be discontinued 3 to 4 hours before pulling the sheath, and an aPTT less than 45 seconds or an ACT of less than 150 seconds should be documented. ■ Care should be taken to obtain proper hemostasis after removal of the sheath using standard compressive techniques followed by close observation. Sheath hemostasis should be achieved at least 2 to 4 hours before hospital discharge.

Patient Education:

Compliance with all measures to minimize bleeding (e.g., strict bed rest, positioning) is imperative. ■ Avoid use of razors, toothbrushes, and other sharp items. ■ Use caution while moving to avoid excessive bumping. ■ Report all episodes of bleeding and apply local pressure if indicated. ■ Expect oozing from IV sites.

Maternal/Child:

Category B: safety for use in pregnancy not established; use only if clearly needed. ■ It is not known whether eptifibatide is excreted in breast milk; use caution if administered to a nursing mother. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Dose adjusted by weight; see Dosing Charts by Weight in Usual Dose. ■ Clearance decreased and plasma levels increased in older patients; incidence of bleeding complications was higher and eptifibatide-associated bleeding was greater in the elderly during studies. ■ No apparent difference in effectiveness between older and younger patients.

DRUG/LAB INTERACTIONS

All studies with eptifibatide included the use of **aspirin and heparin.** In the ESPRIT study, **clopidogrel** was administered routinely starting the day of PCI. Concomitant use, although indicated, increases the risk of bleeding. ■ Use caution when given with **drugs that affect hemostasis** such as **thrombolytics, oral anticoagulants, NSAIDs, dipyridamole, clopidogrel, selected antibiotics** (e.g., cefotetan). ■ Avoid concomitant treatment with **other inhibitors of platelet receptor glycoprotein GPIIb/IIIa** (e.g., tirofiban); may have potentially serious additive effects. See Contraindications.

SIDE EFFECTS

Bleeding is the most frequent adverse event; may occur more frequently in patients undergoing CABG or PCI, or in the elderly or those weighing less than 70 kg. Bleeding is usually reported as mild oozing, but major bleeding (e.g., GI bleeding, pulmonary hemorrhage, intracranial hemorrhage, and stroke) may occur. Fatal bleeding events have been reported. Laboratory findings related to bleeding include decrease in hemoglobin, hematocrit, and platelet count and occult blood in urine and feces. Other side effects that have been reported include hypersensitivity reactions, hypotension, and thrombocytopenia (acute and profound). Incidence in studies similar to that seen with placebo.

Acute toxicity:

Specific information not available for humans, but decreased muscle tone, dyspnea, loss of righting reflex, petechial hemorrhages in the femoral and abdominal areas, and ptosis occurred in animals.

Post-Marketing:

Immune-mediated thrombocytopenia.

ANTIDOTE

Keep physician informed of laboratory values and side effects. Discontinue the infusion of eptifibatide and heparin if any serious bleeding not controllable with pressure occurs, if CABG surgery is initiated, and/or if patient requires thrombolytic therapy. If acute profound thrombocytopenia occurs or the platelet count drops to less than 100,000/mm^3, heparin and eptifibatide should be discontinued. Monitor serial platelet counts, assess the presence of drug-dependent antibodies, and initiate appropriate therapy as indicated. Monitor closely; platelet transfusion may be required. If a hypersensitivity reaction should occur, discontinue the infusion and treat as indicated by severity (e.g., epinephrine, dopamine, theophylline, antihistamines such as diphenhydramine, and/or corticosteroids as necessary). No specific antidote is available. Platelet inhibition reverses rapidly when infusion is discontinued. Hemodialysis may be useful in an overdose situation.

EPTINEZUMAB-jjmr

(**EP**-ti-**NEZ**-ue-mab)
Vyepti
Antimigraine agent
Calcitonin gene-related peptide (CGRP) receptor antagonist
Monoclonal antibody
CGRP antagonist

USUAL DOSE

100 mg every 3 months; some patients may require 300 mg every 3 months.

PEDIATRIC DOSE

Not established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustment is provided by the manufacturer.

Hepatic:

No dosage adjustments are provided by the manufacturer.

DILUTION

IV infusion:

Dilute only in 100 mL NS. **Do not shake**; gently invert the diluted solution to mix; discard unused portion remaining in vial. Infusion bags must be made of polyvinyl chloride, polyethylene, or polyolefin.

100-mg dose:

Withdraw 1 mL of eptinezumab and dilute in a 100-mL NS bag, which gives a final concentration of 1 mg/mL.

300-mg dose:

Withdraw 3 mL eptinezumab and dilute in a 100-mL NS bag to a final concentration of 3 mg/mL.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than normal saline.

RATE OF ADMINISTRATION

After dilution, infuse IV over 30 minutes. Do not give as an IV push or bolus injection. Use an infusion set with a 0.2-micron or 0.22-micron in-line or add-on sterile filter. Do not mix or infuse other medications in the same infusion set. Flush line with 20 mL NS after infusion.

ACTIONS

Eptinezumab is a monoclonal antibody that binds to calcitonin gene-related peptide ligand and blocks its binding to the receptor.

INDICATIONS AND USES

Migraine prophylaxis.

CONTRAINDICATIONS

Hypersensitivity to eptinezumab or any component of the formulation.

PRECAUTIONS

Hypersensitivity reactions, including angioedema, facial flushing, itching, and rash, have occurred. Some dosage forms may contain polysorbate 80 (also known as *Tween 80*) which may cause hypersensitivity reactions, usually a delayed reaction.

Monitor:

Monitor for signs and symptoms of hypersensitivity reactions.

Patient Education:

Promptly report any signs of hypersensitivity (e.g., rash, hives, itching, wheezing, trouble breathing or swallowing, chest tightness, hoarseness, swelling of mouth, face, lips or tongue).

Maternal/Child:

There are no adequate data on developmental risks associated with the use of eptinezumab in pregnant or lactating women.

Elderly:

Refer to adult dosing and precautions.

DRUG/LAB INTERACTIONS

There are no significant drug interactions.

SIDE EFFECTS

Antibody development, nausea, hypersensitivity reactions, fatigue, nasopharyngitis.

ANTIDOTE

There is no antidote. Stop infusion at the first sign of hypersensitivity and treat appropriately.

ERAVACYCLINE

(er-a-va-**SYE**-kleen)
Xerava
Antibacterial (tetracycline)
pH 5.5 to 7

USUAL DOSE

1 mg/kg as an IV infusion over approximately 60 minutes every 12 hours. The recommended duration of treatment with eravacycline for a complicated intra-abdominal infections (cIAI) is 4 to 14 days. The duration of therapy should be guided by the severity and location of infection and the patient's clinical response.

DOSE ADJUSTMENTS

In patients with severe hepatic impairment (Child-Pugh C), administer eravacycline 1 mg/kg IV every 12 hours on Day 1 followed by 1 mg/kg every 24 hours on Day 2 for a total duration of 4 to 14 days. ■ No dose adjustment is warranted in patients with mild to moderate hepatic impairment (Child-Pugh A and Child-Pugh B), in patients with any degree of renal impairment, or based on age. ■ With concomitant use of a strong CYP3A inducer, administer eravacycline 1.5 mg/kg every 12 hours for a total duration of 4 to 14 days. No dosage adjustment is warranted in patients with concomitant use of a weak or moderate CYP3A inducer; see Drug/Lab Interactions.

DILUTION

Available as a yellow to orange, lyophilized powder in single-dose vials containing 50 mg of eravacycline. Calculate the dose of eravacycline based on the patient weight (1 mg/kg). Reconstitute the required number of vials needed to make the dose by injecting 5 mL of SWFI into each vial (final concentration 10 mg/mL). Swirl the vial(s) gently to dissolve. **Do not shake.** The reconstituted product should be a clear, pale-yellow to orange solution. The reconstituted solution must be further diluted with NS to a target final concentration of 0.3 mg/mL (range 0.2 to 0.6 mg/mL). To dilute the reconstituted solution, withdraw the calculated dose and add it to a NS infusion bag to generate an infusion solution with the target concentration (e.g., a 70-kg patient will require a 70-mg dose. Add 70 mg [7 mL] to a 250 mL bag of NS to provide a final concentration of approximately 0.27 mg/mL). **Do not shake the bag.**

Filter:

Data not available.

Storage:

Store unopened vials in original carton at 2° to 8° C (36° to 46° F). The reconstituted and diluted solutions must be infused within 6 hours if stored at RT or within 24 hours if stored at 2° to 8° C (36° to 46° F). Do not freeze. Discard unused portions of the reconstituted or diluted solution.

COMPATIBILITY

Manufacturer states, “Eravacycline is compatible with NS. **Compatibility** with other drugs and infusion solutions has not been established. Eravacycline should not be mixed with other drugs or added to solutions containing other drugs.”

RATE OF ADMINISTRATION

Administer as an IV infusion over approximately 60 minutes. May be administered through a dedicated line or through a Y-site. If the same IV line is used for sequential infusion of several drugs, the line should be flushed with NS before and after the infusion of eravacycline.

ACTIONS

A synthetic fluorocycline antibacterial within the tetracycline class of antibacterial drugs. Eravacycline disrupts bacterial protein synthesis by binding to the 30s ribosomal subunit, thus preventing the incorporation of amino acid residues into elongating peptide chains. In general, eravacycline is bacteriostatic against gram-positive bacteria (e.g., *Staphylococcus aureus* and *Enterococcus faecalis*); however, in vitro bactericidal activity has been demonstrated against certain strains of *Escherichia coli* and *Klebsiella pneumoniae*. Active against selected gram-positive and gram-negative aerobic and anaerobic bacteria; see prescribing information and Indications. Protein binding to human plasma proteins increases with increasing plasma concentrations. Metabolized primarily by CYP3A4- and FMO-mediated oxidation. Half-life is 20 hours. Excreted in urine and feces.

INDICATIONS AND USES

Treatment of complicated intra-abdominal infections (cIAI) caused by susceptible microorganisms in patients 18 years or older. Organisms that may be susceptible include: *E. coli, K. pneumoniae, Citrobacter freundii, Enterobacter cloacae, Klebsiella oxytoca, E. faecalis, Enterococcus faecium, S. aureus, Streptococcus anginosus* group, *Clostridium perfringens, Bacteroides* species, and *Parabacteroides distasonis*.

Limitation of use:

Eravacycline is not indicated for treatment of a complicated urinary tract infection (cUTI).

CONTRAINDICATIONS

Known hypersensitivity to eravacycline, tetracycline-class antibacterial drugs, or to any of the excipients. Not recommended in pediatric patients under 8 years or in breast-feeding.

PRECAUTIONS

For IV use only. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, eravacycline should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to eravacycline. ■ Life-threatening hypersensitivity (anaphylactic) reactions have been reported. Eravacycline is structurally similar to other tetracycline-class antibacterial drugs and should be not be administered to patients with known hypersensitivity to any drug in this class. ■ Exposure during the last half of pregnancy, infancy, and childhood to the age of 8 years may cause permanent discoloration of the teeth. This adverse reaction is more common during long-term use of the tetracycline-class drugs but has also been observed following repeated short-term courses. Enamel hypoplasia has also been reported with the tetracycline-class drugs. ■ The use of eravacycline during the second and third trimester of pregnancy, infancy, and childhood up to the age of 8 years may cause reversible inhibition of bone growth. All tetracyclines form a stable calcium complex in any bone-forming tissue. ■ Eravacycline is structurally similar to tetracycline-class antibacterial drugs and may have similar adverse reactions. Adverse reactions including photosensitivity, pseudotumor cerebri, and anti-anabolic action leading to increased BUN, azotemia, acidosis, hyperphosphatemia, pancreatitis, and abnormal liver function tests have been reported for other tetracycline-class antibacterial drugs and may occur with eravacycline. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with eravacycline. ■ May be active against some organisms that are normally resistant to other tetracyclines.

Monitor:

Monitor for S/S of hypersensitivity reactions. ■ Determine absolute patency of vein and avoid extravasation; thrombophlebitis may occur. ■ Monitor hematopoietic, renal, and hepatic studies periodically in long-term therapy. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report severe diarrhea, S/S of hypersensitivity reactions, or any other side effect. ■ May cause permanent tooth discoloration of deciduous teeth and reversible inhibition of bone growth when administered during the second and third trimesters of pregnancy. Tell your health care provider right away if you become pregnant during treatment. ■ Alert patient to the possibility of a photosensitive skin reaction. ■ May impair spermiation and sperm maturation. Long-term effects on male fertility have not been studied.

Maternal/Child:

Data on use in pregnant women are limited. May cause permanent tooth discoloration of deciduous teeth and reversible inhibition of bone growth when administered during the second and third trimesters of pregnancy. Consider risk versus benefit. ■ Discontinue breast-feeding during treatment and for 4 days after the last dose. ■ Safety and effectiveness of eravacycline in pediatric patients have not been established. Due to the adverse effects on tooth development and bone growth, use in pediatric patients less than 8 years of age is not recommended.

Elderly:

No overall differences in safety or efficacy were observed between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Concomitant use of **strong CYP3A inducers** (e.g., rifampin decreases the exposure of eravacycline, which may reduce its efficacy. Increase eravacycline dose if concomitant use of a strong CYP3A inducer is required; see Dose Adjustments. ■ Because tetracyclines have been shown to depress plasma prothrombin activity, patients who are on **anticoagulant therapy** may require downward adjustment of their anticoagulant dosage. ■ In vitro studies have not demonstrated antagonism between eravacycline and other commonly used antibacterial drugs for the indicated pathogens.

SIDE EFFECTS

The most common adverse reactions are infusion site reactions, nausea, and vomiting. Less commonly reported adverse reactions included diarrhea, hypotension, and wound dehiscence. Several other adverse reactions were reported in fewer than 1% of patients. *C. difficile*–associated diarrhea, hypersensitivity reactions, inhibition of bone growth, tetracycline-class adverse reactions and tooth discoloration have been reported; see Precautions.

ANTIDOTE

Notify the physician of all side effects. Discontinue eravacycline at the first sign of a hypersensitivity reaction or if the development of any tetracycline-class adverse drug reaction is suspected. Treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Significant quantities are not expected to be removed by hemodialysis.

ERIBULIN MESYLATE

(**ER**-ih-**BUE**-lin **MES**-ih-late)
Halaven
Antineoplastic (antimicrotubular)
pH 6.5 to 8.5

USUAL DOSE

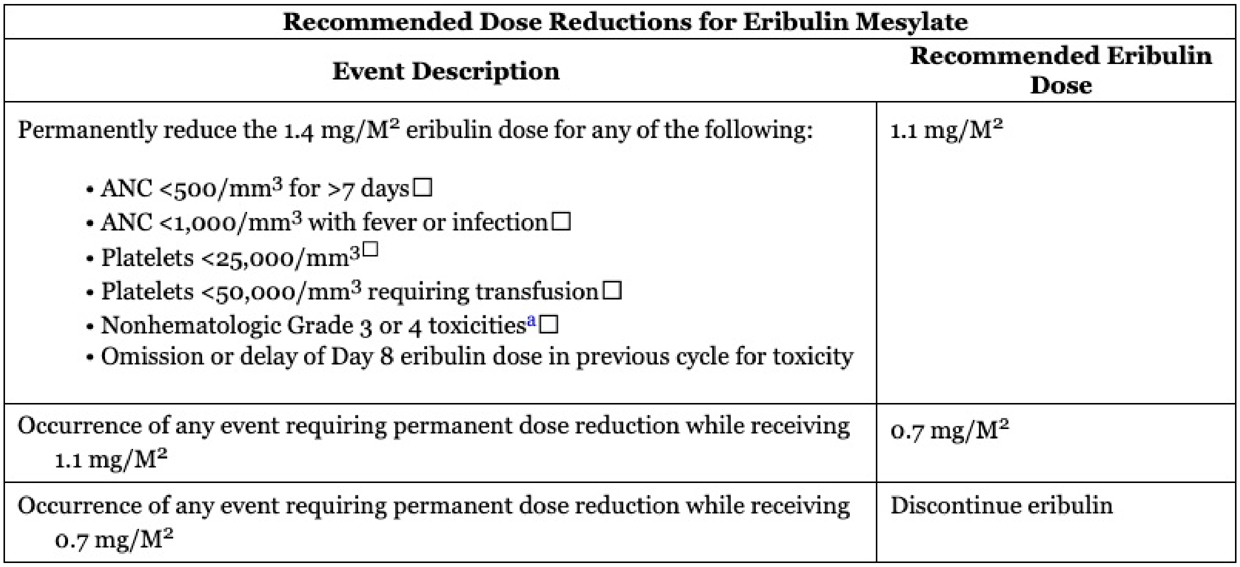
Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

1.4 mg/M² IV over 2 to 5 minutes on Days 1 and 8 of a 21-day cycle.

DOSE ADJUSTMENTS

Dose adjustment not required based on age, gender, or race. ■ Reduce dose in patients with mild hepatic impairment (Child-Pugh Class A) to 1.1 mg/M^2 IV. ■ Patients with moderate hepatic impairment (Child-Pugh Class B) should receive 0.7 mg/M^2 IV. ■ Patients with moderate or severe renal impairment (CrCl 15 to 49 mL/min) should receive 1.1 mg/M^2 IV. ■ Do not administer dose on Day 1 or Day 8 in patients with an ANC less than 1,000/mm^3, platelets less than 75,000/mm^3, or Grade 3 or 4 nonhematologic toxicities. ■ The Day 8 dose may be delayed for a maximum of 1 week. If toxicities do not resolve or improve to Grade 2 or less by Day 15, omit the dose. If toxicities resolve or improve to Grade 2 or less by Day 15, administer at a reduced dose as outlined in the following chart and initiate the next cycle no sooner than 2 weeks later. ■ If a dose has been delayed for toxicity and the toxicities have recovered to Grade 2 severity or less, resume eribulin as outlined in the following chart. ■ Do not re-escalate eribulin dose after it has been reduced.



Recommended Dose Reductions for Eribulin Mesylate

Event Description	Recommended Eribulin Dose
Permanently reduce the 1.4 mg/M^2 eribulin dose for any of the following: • ANC <500/mm^3 for >7 days☐ • ANC <1,000/mm^3 with fever or infection☐ • Platelets <25,000/mm^3☐ • Platelets <50,000/mm^3 requiring transfusion☐ • Nonhematologic Grade 3 or 4 toxicities[a]☐ • Omission or delay of Day 8 eribulin dose in previous cycle for toxicity	1.1 mg/M^2
Occurrence of any event requiring permanent dose reduction while receiving 1.1 mg/M^2	0.7 mg/M^2
Occurrence of any event requiring permanent dose reduction while receiving 0.7 mg/M^2	Discontinue eribulin

[a]Toxicities graded in accordance with National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE), Version 3.0.

DILUTION

***Specific techniques required; see* Precautions.** Available in a single-use vial containing 1 mg/2 mL (0.5 mg/mL). Withdraw calculated dose and administer undiluted or may dilute in 100 mL NS.

Filter:

Information not available.

Storage:

Store unopened vials in carton at CRT. Do not freeze. Store undiluted solution drawn up into a syringe for up to 4 hours at RT or 24 hours under refrigeration (4° C [40° F]). Store diluted solution for up to 4 hours at RT or 24 hours under refrigeration (4° C [40° F]). Discard unused portion of vial.

COMPATIBILITY

Manufacturer states, “Do not dilute in or administer through an IV line containing solutions with dextrose. Do not administer in the same intravenous line concurrent with other medicinal products.”

RATE OF ADMINISTRATION

An IV injection evenly distributed over 2 to 5 minutes.

ACTIONS

A synthetic analog of halichondrin B, a product isolated from a marine sponge. Eribulin is a non-taxane microtubule inhibitor. Inhibits the growth phase of microtubules without affecting the shortening phase and sequesters tubulin into nonproductive aggregates. Exerts its effects via a tubulin-based antimitotic mechanism leading to G_2/M cell-cycle block, disruption of mitotic spindles and, ultimately, apoptotic cell death after prolonged mitotic blockage. Plasma protein binding is 49% to 65%. Mean elimination half-life is approximately 40 hours. There are no major human metabolites. Is eliminated primarily in feces unchanged. Small amount excreted as unchanged drug in urine.

INDICATIONS AND USES

Treatment of patients with metastatic breast cancer who have previously received at least two chemotherapeutic regimens for the treatment of metastatic disease. Prior therapy should have included an anthracycline and a taxane in either the adjuvant or metastatic setting. ■ Treatment of patients with unresectable or metastatic liposarcoma who have received a prior anthracycline-containing regimen.

CONTRAINDICATIONS

Manufacturer states, “None.” ■ Do not administer in patients with an ANC less than 1,000/mm^3, platelets less than 75,000/mm^3, or Grade 3 or 4 nonhematologic toxicities. ■ Should be avoided in patients with congenital long QT syndrome.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ May cause severe neutropenia (ANC less than 500/mm^3) lasting more than 1 week. Higher incidence of Grade 4 neutropenia and febrile neutropenia seen in patients with ALT or AST greater than 3 times the ULN and in patients with a bilirubin greater than 1.5 times the ULN. Deaths from complications of febrile neutropenia and neutropenic sepsis have been reported. In clinical trials, the mean time to nadir was 13 days, and the mean time to recovery from severe neutropenia was 8 days. ■ Grades 3 and 4 peripheral neuropathy have been reported. Peripheral neuropathy was the most common toxicity leading to discontinuation of therapy. Neuropathy may not be reversible. ■ QT prolongation, independent of eribulin concentration, was observed on Day 8 in an uncontrolled, open-label ECG study. ■ Has not been studied in patients with severe hepatic impairment (Child-Pugh Class C). ■ See Dose Adjustments.

Monitor:

Obtain baseline CBC with platelets, bilirubin, liver function tests, SCr, and electrolytes. ■ Obtain CBC with platelets before each dose. Increase frequency of hematologic monitoring in patients who develop severe cytopenias (Grade 3 or 4); see Dose Adjustments. ■ Assess for peripheral motor and sensory neuropathy before each dose; see Dose Adjustments. ■ ECG monitoring is recommended in patients with CHF or bradyarrhythmias; in patients taking drugs that prolong the QT interval, such as Class Ia and III antiarrhythmics (e.g., amiodarone, disopyramide, dofetilide, ibutilide, *N*-acetylprocainamide, procainamide, quinidine, sotalol); and in patients with electrolyte abnormalities. Correct hypokalemia or hypomagnesemia before initiating therapy, and monitor electrolytes periodically during therapy. ■ Monitor for nausea and vomiting. Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ In patients with thrombocytopenia (platelet count less than 50,000/mm^3), initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Read FDA-approved patient information. ■ Avoid pregnancy. Women should use effective contraception during treatment with eribulin and for 2 weeks following the final dose. Males with female partners of reproductive potential should use effective contraception during treatment and for 3.5 months following the final dose. ■ May result in damage to male reproductive tissues, leading to impaired fertility of unknown duration. ■ Promptly report S/S of infection (e.g., fever, chills, cough, burning or pain on urination). ■ Report symptoms of peripheral neuropathy (e.g., numbness, tingling, or burning in hands or feet).

Maternal/Child:

Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety were observed between older and younger patients. ■ Consider age-related cardiac, hepatic, or renal dysfunction.

DRUG/LAB INTERACTIONS

No drug-drug interactions are expected with CYP3A4 inhibitors, CYP3A4 inducers, or P-glycoprotein (P-gp) inhibitors. ■ A substrate and a weak inhibitor of the drug efflux transporter P-gp in vitro.

SIDE EFFECTS

The most common side effects were abdominal pain, alopecia, anemia, asthenia, constipation, fatigue, fever, nausea, neutropenia, and peripheral neuropathy. The most common serious side effects were febrile neutropenia and neutropenia. The most common side effects resulting in discontinuation of eribulin were fatigue, peripheral neuropathy, and thrombocytopenia. Grade 3 or 4 laboratory abnormalities included hypocalcemia, hypokalemia, and neutropenia. Other reported side effects included anorexia, arthralgia, cough, diarrhea, dyspnea, headache, liver function test abnormalities, mucosal inflammation, myalgia, pain (back, bone, extremity), UTI, vomiting, and weight loss. Less frequently reported side effects included anxiety, depression, dizziness, dry mouth, dysgeusia, dyspepsia, hyperglycemia, hypophosphatemia, hypotension, increased lacrimation, insomnia, muscle spasm or weakness, oropharyngeal pain, peripheral edema, rash, stomatitis, and upper respiratory tract infection.

Post-Marketing:

Dehydration, hepatotoxicity, hypersensitivity, hypomagnesemia, interstitial lung disease, lymphopenia, neutropenic sepsis, pancreatitis, pneumonia, pruritus, sepsis, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Neutropenia can be profound. Colony-stimulating factors (G-CSF [filgrastim], GM-CSF [sargramostim]) have been administered to aid in neutrophil recovery. Severe peripheral neuropathies may necessitate discontinuation of eribulin. There is no specific antidote for overdose. Supportive therapy will help sustain the patient in toxicity. Resuscitate if indicated.

ERTAPENEM

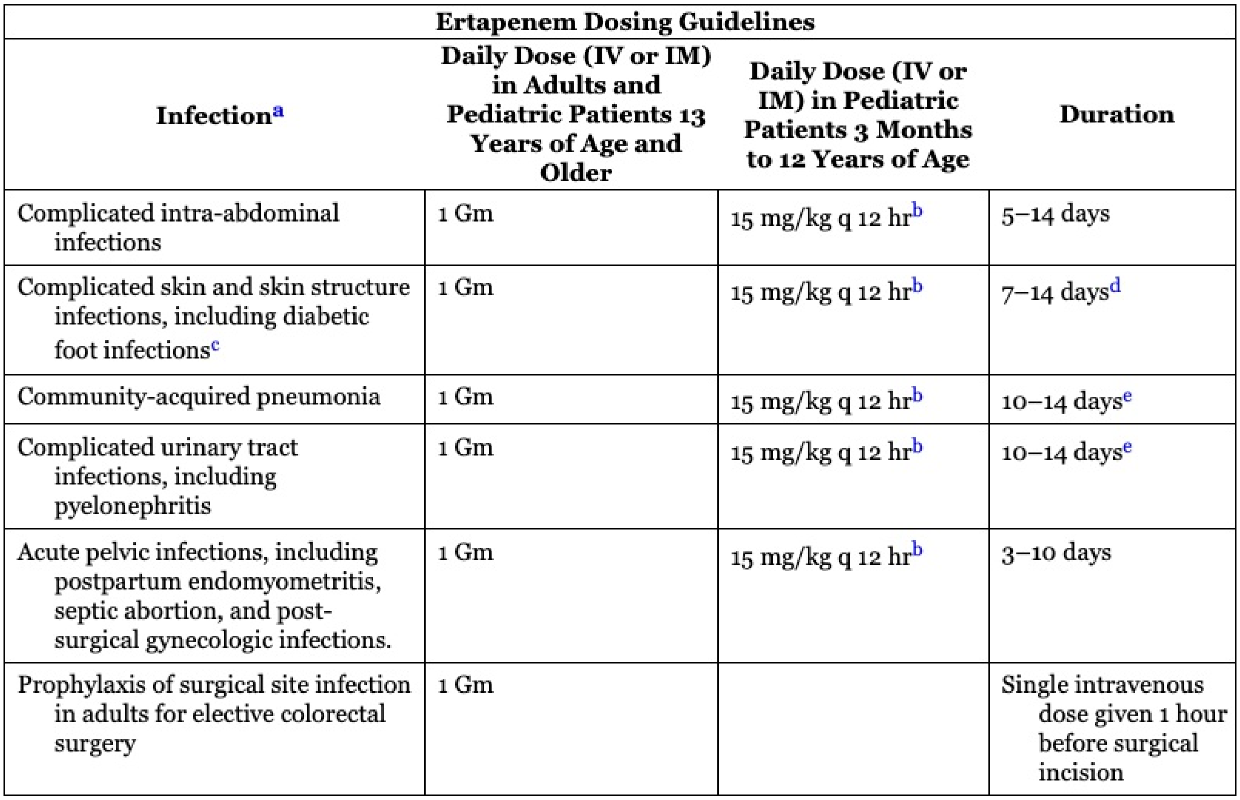
(er-tah-**PEN**-em)
Invanz
Antibacterial (carbapenem)
pH 7.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Duration of therapy is based on diagnosis as listed in the following chart. May be given IV for up to 14 days or IM for up to 7 days.



Ertapenem Dosing Guidelines			
Infection[a]	**Daily Dose (IV or IM) in Adults and Pediatric Patients 13 Years of Age and Older**	**Daily Dose (IV or IM) in Pediatric Patients 3 Months to 12 Years of Age**	**Duration**
Complicated intra-abdominal infections	1 Gm	15 mg/kg q 12 hr[b]	5–14 days
Complicated skin and skin structure infections, including diabetic foot infections[c]	1 Gm	15 mg/kg q 12 hr[b]	7–14 days[d]
Community-acquired pneumonia	1 Gm	15 mg/kg q 12 hr[b]	10–14 days[e]
Complicated urinary tract infections, including pyelonephritis	1 Gm	15 mg/kg q 12 hr[b]	10–14 days[e]
Acute pelvic infections, including postpartum endomyometritis, septic abortion, and post-surgical gynecologic infections.	1 Gm	15 mg/kg q 12 hr[b]	3–10 days
Prophylaxis of surgical site infection in adults for elective colorectal surgery	1 Gm		Single intravenous dose given 1 hour before surgical incision

[a] Due to designated pathogens.

[b] Not to exceed 1 Gm/24 hr.

[c] Has not been studied in diabetic foot infections with concomitant osteomyelitis.

[d] Adult patients with diabetic foot infections received up to 28 days of treatment (parenteral or parenteral plus oral switch therapy).

[e] Duration includes a possible switch to an appropriate oral therapy, after at least 3 days of parenteral therapy, once clinical improvement has been demonstrated.

DOSE ADJUSTMENTS

Reduce dose to 0.5 Gm (500 mg) daily in adults with a CrCl at or less than 30 mL/min/1.73 M^2, including adults with end-stage renal insufficiency (CrCl ≤10 mL/min/1.73 M^2). No dose adjustment indicated in adults with a CrCl at or more than 31 mL/min/1.73 M^2. Give a supplementary dose of 150 mg to patients who received the daily dose within 6 hours of a dialysis session. No data are available for pediatric patients with renal insufficiency or pediatric patients on hemodialysis. No data on patients undergoing peritoneal dialysis or hemofiltration. ■ No dose adjustment indicated based on age or gender. The pharmacokinetics of ertapenem in patients with hepatic impairment have not been established. Dose recommendations are not available. ■ Dosing should be cautious in the elderly, and reduced doses may be indicated based on potential for decreased organ function.

DILUTION

Reconstitute each 1-Gm vial of ertapenem with 10 mL SWFI, NS, BWFI using a syringe equipped with a 21-gauge or smaller diameter needle. Use with a needleless IV system is **not** recommended. Shake well to dissolve, and dilute immediately as outlined below.

Adults and pediatric patients 13 years of age and older:

Further dilute in 50 mL of NS.

Pediatric patients 3 months to 12 years of age:

Withdraw the volume equal to the 15 mg/kg dose and dilute in NS to a final concentration of 20 mg/mL or less.

Storage:

Store unopened vials at or below 25° C (77° F). Dilute reconstituted solution immediately. Use diluted solution within 6 hours when stored at RT. May refrigerate for up to 24 hours and use within 4 hours after removal. Do not freeze.

COMPATIBILITY

Manufacturer states, “Do not mix or co-infuse ertapenem with other medications. Do not use diluents containing dextrose.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes.

ACTIONS

A unique, synthetic 1-beta-methyl-carbapenem structurally related to beta-lactam antibiotics. Effective against gram-positive and gram-negative aerobic and anaerobic bacteria. May effectively replace some combination therapies. Does not cover *Pseudomonas* and *Acinetobacter* species. Bactericidal activity results from inhibition of bacterial cell wall synthesis. Stable against hydrolysis by a variety of beta-lactamases, including penicillinases, cephalosporinases, and extended-spectrum beta-lactamases. Hydrolyzed by metallo-beta-lactamases. Widely distributed throughout the body into many body tissues and fluids. Highly protein bound. Average half-life is 4 hours. Primarily excreted in urine (some as unchanged drug). Some excretion in feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of adult and pediatric patients with moderate to severe infections caused by susceptible strains of microorganisms in conditions that include complicated intra-abdominal infections; complicated skin and skin structure infections, including diabetic foot infections **without** osteomyelitis; community-acquired pneumonia; complicated urinary tract infections, including pyelonephritis; and acute pelvic infections, including postpartum endomyometritis, septic abortion, and postsurgical gynecologic infections. ■ Prophylaxis of surgical site infections in adults following elective colorectal surgery. ■ Not recommended for use in the treatment of meningitis in pediatric patients (lack of sufficient CSF penetration).

CONTRAINDICATIONS

Known hypersensitivity to any component of ertapenem or other drugs in the same class (e.g., imipenem-cilastatin), or in patients who have had anaphylactic reactions to beta-lactams (e.g., penicillins and cephalosporins); see Precautions.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, ertapenem should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Culture and sensitivity studies indicated to determine susceptibility of the causative organism to ertapenem. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams. More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history and watch for early symptoms of hypersensitivity reactions. Emergency equipment must be readily available; cross-sensitivity is possible. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ CNS stimulation and seizures have been reported. Use with caution in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ertapenem. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Monitor closely for S/S of hypersensitivity reactions (e.g., difficulty breathing, itching, rash, swelling of eyelids, lips, or face). ■ Obtain baseline CBC with differential and platelets, and baseline kidney and liver studies (e.g., CrCl, serum creatinine, ALT, AST, serum bilirubin). Monitor periodically during prolonged therapy. ■ Monitor patients who are at risk for CNS stimulation or are receiving anticonvulsant therapy. If focal tremors, myoclonus, or seizures occur, neurologic evaluation and dose reduction or discontinuation of ertapenem may be indicated. ■ Monitor IV site carefully and rotate as indicated. ■ See Precautions.

Patient Education:

Promptly report S/S of hypersensitivity reaction (e.g., rash, shortness of breath, hives), fever, sore throat, unusual bleeding or bruising, severe stomach cramps, seizures, and pain or discomfort at the injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking ertapenem; see Drug/Lab Interactions.

Maternal/Child:

Available data insufficient to inform any drug-associated risks for major birth defects, miscarriage, or adverse maternal or fetal outcomes. Use during pregnancy only if clearly needed. ■ There are no data on the effects on the breast-fed infant or the effects on milk production; is found in breast milk. Benefits must outweigh risks to infant (e.g., diarrhea, candidiasis, or allergic response). Undetectable in breast milk 5 days after ertapenem is discontinued. ■ Following a 1-Gm daily IV dose, plasma concentrations and half-life of ertapenem in pediatric patients 13 to 17 years of age are comparable to those in adults. ■ Compared to plasma clearance in adults, plasma clearance (mL/min/kg) in pediatric patients 3 months to 12 years of age is approximately two-fold higher. 30 mg/kg/24 hr (15 mg/kg every 12 hours) is comparable to a 1-Gm dose daily in adults. Half-life in pediatric patients 3 months to 12 years of age is 2.5 hours compared to 4 hours for adults and pediatric patients 13 years of age or older. ■ Not recommended for use in infants under 3 months; no data available; see Indications and Uses.

Elderly:

Dosing should be cautious in the elderly; see Dose Adjustments. ■ Response similar to that seen in younger patients, but may be more sensitive to side effects. ■ Monitoring of renal function may be indicated.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in a loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of ertapenem is necessary, supplemental anticonvulsant therapy should be considered. ■ **Probenecid** reduces the renal clearance of ertapenem, resulting in increased plasma concentrations. Coadministration is not recommended.

SIDE EFFECTS

Adults:

Diarrhea, headache, infusion site reactions, nausea, and vaginitis in females were most common and described as mild to moderate. Other side effects that were reported in greater than 2% of patients included abdominal pain, altered mental status, constipation, dizziness, dyspnea, edema/swelling, fever, hypotension, insomnia, pruritus, rash, and vomiting. The most commonly reported laboratory abnormalities were elevated ALT, AST, and alkaline phosphatase; decreased hemoglobin and hematocrit; and increased platelets and eosinophils. Serious but less frequently reported adverse events included CDAD, CNS stimulation (e.g., aggressive behavior, anxiety, depression, insomnia, nervousness, seizures, tremor), hypersensitivity reactions (e.g., anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, laryngeal, or pharyngeal], hypotension, itching, rash, shock, urticaria), and pseudomembranous colitis. Numerous other side effects occurred in fewer than 1% of patients.

Pediatric patients:

Side effects similar to adults. Diarrhea, infusion site pain, erythema, and vomiting were most common.

Post-Marketing:

Abnormal coordination, acute generalized exanthematous pustulosis (AGEP), altered mental status (including aggression, delirium, and hallucinations), anaphylaxis, depressed level of consciousness, drug rash with eosinophilia and systemic symptoms (DRESS syndrome), dyskinesia, gait disturbance, muscular weakness, myoclonus, teeth staining, tremor.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue ertapenem at the first sign of hypersensitivity (e.g., skin rash). Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated; may require dose reduction and/or anticonvulsants (e.g., phenytoin, diazepam) for seizures. Mild cases of CDAD may respond to discontinuation of the drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin), as indicated. In severe cases, surgical evaluation may be indicated. Ertapenem is partially removed by hemodialysis.

ERYTHROMYCIN LACTOBIONATE

(eh-**rih**-throw-**MY**-sin **LAK**-to-**bye**-oh-nayt)
Erythrocin
Antibacterial (macrolide)
pH 6.5 to 7.7

USUAL DOSE

IV formulation used when oral administration is not possible or when the severity of the infection requires immediate high serum levels of erythromycin. Begin oral therapy as soon as practical.

Antibacterial:

15 to 20 mg/kg of body weight/24 hr in equally divided doses every 6 hours (3.75 to 5 mg/kg every 6 hours). Range is 350 to 500 mg every 6 hours. Continuous infusion over 24 hours is preferred. Up to 4 Gm/24 hr has been given for severe infections. See Elderly.

Legionnaires' disease:

1 to 4 Gm/day in divided doses (250 mg to 1 Gm every 6 hours). Optimum doses not established.

Pelvic inflammatory disease:

500 mg every 6 hours for 3 days. Follow with oral erythromycin 250 mg every 6 hours for 7 days.

Diabetic gastroparesis (unlabeled):

200 mg immediately before each meal. When practical, continue treatment with oral erythromycin 3 times daily, 30 minutes before meals, for 4 weeks.

PEDIATRIC DOSE

15 to 20 mg/kg of body weight/24 hr in equally divided doses every 6 hours is recommended (3.75 to 5 mg/kg every 6 hours). Another source recommends 20 to 50 mg/kg/24 hr in equally divided doses every 6 hours (5 to 12.5 mg/kg every 6 hours). See Maternal/Child.

DOSE ADJUSTMENTS

Reduced dose may be required in impaired liver function.

DILUTION

Each 500 mg must be reconstituted with 10 mL of SWFI without preservatives to avoid precipitation. Forms a 5% solution. Shake well to ensure dilution. May be further diluted with NS, Normosol, or LR. If a dextrose solution is used, add sodium bicarbonate (Neut) 1 mL for each 100 mL of solution.

Continuous infusion (preferred):

Further dilute to a 1 mg/mL solution (e.g., each 1 Gm in 1,000 mL of NS, Normosol, or LR).

Intermittent infusion:

Dilute to a final concentration of 1 to 5 mg/mL. No less than 100 mL of IV diluent should be used (1 Gm in 1,000 mL equals 1 mg/mL; 1 Gm in 200 mL equals 5 mg/mL).

Storage:

Store unopened vials at CRT. Solutions diluted from ***lyophilized powder vials*** are stable for 8 hours at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer with a volume control set. A slow infusion rate is recommended to reduce pain along the injection site.

Continuous infusion (preferred):

A 0.1% to 0.2% solution equally distributed over 6 to 24 hours.

Intermittent infusion:

1 Gm or fraction thereof in at least 100 mL over 20 to 60 minutes.

Diabetic gastroparesis (unlabeled):

1 to 3 mg/kg/hr, usually approximately over 15 minutes.

ACTIONS

Macrolide antibiotic, bactericidal and bacteriostatic. Effective against a number of gram-positive and some gram-negative organisms as well as *Mycoplasma pneumoniae*. Inhibits protein synthesis by binding to ribosomal subunits of susceptible organisms. Diffuses readily into most bodily fluids. Metabolized by the liver and excreted in urine and bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of mild to moderate infections of the upper and lower respiratory tract, skin and skin structures, and gynecologic infections caused by susceptible organisms. ■ Alternative treatment in several sexually transmitted diseases in females with a history of penicillin sensitivity. ■ Legionnaires' disease. ■ Additional indications listed for oral formulation.

Unlabeled uses:

Diabetic gastroparesis.

CONTRAINDICATIONS

Known erythromycin sensitivity. See Drug/Lab Interactions. ■ Coadministration with ritonavir is contraindicated. Contraindicated when used concomitantly with HMG-CoA reductase inhibitors (statins) that are extensively metabolized by cytochrome P_{450} isoform 3A4 (lovastatin or simvastatin) due to the increased risk of myopathy, including rhabdomyolysis.

PRECAUTIONS

IV formulation used when oral administration is not possible or when the severity of the infection requires immediate high serum levels of erythromycin. Switch to oral therapy when appropriate. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to erythromycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, erythromycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in impaired liver function. ■ Hepatic dysfunction, with or without jaundice, has been reported in patients taking oral erythromycin. ■ Use caution in patients with a history of cardiac disease. Life-threatening episodes of ventricular tachycardia associated with prolonged QT intervals (torsades de pointes) have been reported. ■ Use caution in patients with myasthenia gravis; weakness may be aggravated. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with erythromycin. ■ Hypersensitivity reactions, including anaphylaxis have occurred; emergency equipment, medications, and supplies must be available.

Monitor:

Monitor vital signs. ■ Monitor for development of torsades de pointes related to electrolyte imbalance, hepatic dysfunction, myocardial ischemia, left ventricular dysfunction, idiopathic QT prolongation, and concurrent antiarrhythmic therapy. ■ Monitor IV site for redness and inflammation. ■ Monitor for S/S of hypersensitivity reactions (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). ■ See Drug/Lab Interactions.

Patient Education:

Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Considered safe for use in breast-feeding; use caution. ■ Some products contain benzyl alcohol; not recommended for use in neonates.

Elderly:

When doses of 4 Gm/day or higher are used, the risk of developing erythromycin-induced hearing loss is increased in elderly patients, particularly those with impaired renal or hepatic function. ■ May be more susceptible to development of torsades de pointes. ■ May experience increased effects of oral anticoagulation; see Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

Contraindicated with **ritonavir.** ■ Antibacterial activity is antagonized by coadministration of **clindamycin, lincomycin, and chloramphenicol.** ■ May inhibit **penicillins.** ■ Will increase serum levels and potentiate the effects of **alfentanil, anticoagulants, bromocriptine, carbamazepine, cyclosporine, digoxin, disopyramide, ergot alkaloids, methylprednisolone, midazolam, phenytoin, theophyllines, triazolam, and valproate;** serious toxicity may result. ■ Plasma concentrations of erythromycin may be increased by **antifungal agents** metabolized by CYP3A4 isoenzymes (e.g., fluconazole, itraconazole). May result in an increase in QT prolongation and ventricular arrhythmias. ■ Severe **vinblastine** toxicity has been reported in conjunction with erythromycin. ■ May increase serum levels of **sildenafil.** ■ Contraindicated when used concomitantly with **HMG-CoA reductase inhibitors** (statins) that are extensively metabolized by cytochrome P_{450} isoform 3A4 (e.g., lovastatin or simvastatin). ■ Coadministration results in increased serum levels of the antihyperlipidemic agent and increases the risk of severe myopathy and rhabdomyolysis. ■ Concurrent use with **theophylline** (aminophylline) may decrease plasma levels of erythromycin. ■ Serotonin syndrome has been reported with coadministration of erythromycin and **serotonin-uptake inhibitors**. ■ May interfere with fluorometric determination of **urinary catecholamines.**

SIDE EFFECTS

Relatively free from side effects when given as directed. Nausea and vomiting, urticaria, and mild local venous discomfort. Increased incidence of usually reversible ototoxicity with larger doses. CDAD; QT prolongation and ventricular arrhythmias, including ventricular tachycardia and torsades de points, and skin reactions ranging from mild eruptions to erythema multiforme, Stevens-Johnson syndrome, and toxic necrolysis have been reported. Hypersensitivity reactions, including anaphylaxis, may occur.

ANTIDOTE

Notify the physician of early or mild symptoms. For severe symptoms, discontinue the drug, treat hypersensitivity reactions, or resuscitate as necessary and notify physician. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Not removed by peritoneal dialysis or hemodialysis.

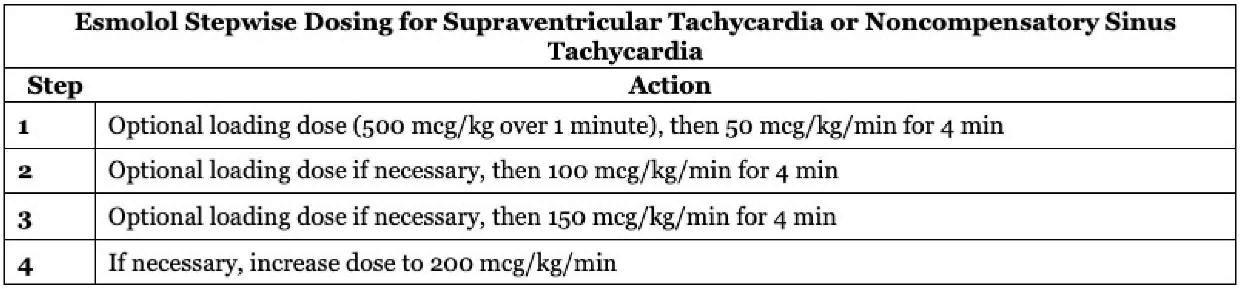
ESMOLOL HYDROCHLORIDE

(**EZ**-moh-lohl hy-droh-**KLOR**-eyed)
Brevibloc
Beta-adrenergic blocking agent
Antiarrhythmic
pH 4.5 to 5.5

USUAL DOSE

Supraventricular tachycardia (SVT) or noncompensatory sinus tachycardia:

Administer by continuous IV infusion with or without a loading dose. Additional loading doses and/or titration of the maintenance infusion (stepwise dosing) may be necessary based on desired ventricular response.



Esmolol Stepwise Dosing for Supraventricular Tachycardia or Noncompensatory Sinus Tachycardia

Step	Action
1	Optional loading dose (500 mcg/kg over 1 minute), then 50 mcg/kg/min for 4 min
2	Optional loading dose if necessary, then 100 mcg/kg/min for 4 min
3	Optional loading dose if necessary, then 150 mcg/kg/min for 4 min
4	If necessary, increase dose to 200 mcg/kg/min

In the absence of loading doses, continuous infusion of a single concentration of esmolol reaches a pharmacokinetic and pharmacodynamic steady-state in about 30 minutes. Effective maintenance dose for continuous and stepwise dosing is 50 to 200 mcg/kg/min, although doses as low as 25 mcg/kg/min have been adequate. Doses greater than 200 mcg/kg/min provide little additional lowering of heart rate, and the rate of adverse reactions increases. Maintenance infusions may be continued for up to 48 hours. See Precautions/Monitor.

Intraoperative and postoperative tachycardia and/or hypertension:

Immediate control:

1 mg/kg over 30 seconds. Follow with an infusion of 150 mcg/kg/min (0.15 mg/kg/min) if necessary. Adjust as required to maintain desired HR and/or BP.

Gradual control:

Use procedure listed for SVT.

Immediate and gradual control:

Higher doses (250 to 300 mcg/kg/min [0.25 to 0.3 mg/kg/min]) may be required to control hypertension. Maintenance infusion doses greater than 200 mcg/kg/min are not recommended for the treatment of tachycardia. They provide little additional lowering of heart rate, and the rate of adverse reactions increases.

Transition to alternative drugs:

After control of HR and BP is achieved and clinical status is stable,

1. Administer the first dose of the alternative drug. In 30 minutes, reduce the esmolol infusion rate by one-half (50%).
2. After administration of the second dose of the alternative drug, monitor patient response carefully. If control is satisfactory and is maintained for 1 hour, discontinue the esmolol infusion.

PEDIATRIC DOSE

See Maternal/Child.

Antiarrhythmic (unlabeled):

Pediatric patients 1 to 12 years of age:

A loading dose of 100 to 500 mcg/kg (0.1 to 0.5 mg/kg) administered over 1 minute. Follow with a maintenance infusion of 25 to 100 mcg/kg/min (0.025 to 0.1 mg/kg/min). Titrate doses upward to response by 50 to 100 mcg/kg/min (0.05 to 0.1 mg/kg/min) at 5- to 10-minute intervals as needed. Dose requirements may be higher than in adults. Doses as high as 1,000 mcg/kg/min have been administered to pediatric patients 1 to 12 years of age.

Antihypertensive (postoperative [unlabeled]):

Pediatric patients 1 to 12 years of age:

A loading dose of 500 mcg/kg (0.5 mg/kg) administered over 1 minute. Follow with a maintenance infusion of 50 to 250 mcg/kg/min (0.05 to 0.25 mg/kg/min). Titrate doses upward 50 to 100 mcg/kg/min (0.05 to 0.1 mg/kg/min) as needed. Titrate to individual desired response. Dose requirements may be higher than in adults. Doses as high as 1,000 mcg/kg/min have been administered to pediatric patients 1 to 12 years of age.

DOSE ADJUSTMENTS

Reduced dose may be required in impaired renal function. No dose adjustment required if the maintenance infusion does not exceed 150 mcg/kg/min for more than 4 hours; no data available for higher doses or longer duration. ■ No dose adjustment indicated in impaired hepatic function. ■ Reduction required with transfer to alternate agent; see Monitor. ■ See Drug/Lab Interactions.

DILUTION

Available premixed as 10 mg/mL in 100 mL NS or as 20 mg/mL in 100 mL NS (double strength). Single-dose vials are available as 100 mg/10 mL and may be given by IV injection without further dilution or may be further diluted in D5W, D5R, D5LR, D5NS, D5/½NS, NS, LR, ½NS, or D5W with KCl 40 mEq/L. Premixed solutions have a delivery port and a medication port (for withdrawing the initial bolus only). Ready-to-use vials may be used to administer initial and subsequent boluses.

Storage:

Store vials and premix at CRT; protect from freezing and avoid excessive heat. Diluted solution stable at room temperature for 24 hours. If a bolus has been removed from the premixed bag, the bag should be used within 24 hours.

COMPATIBILITY

Manufacturer lists as **incompatible** with sodium bicarbonate and furosemide and states, “Do not add any additional medications to the bag” (premixed injection).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

See Usual Dose.

Infusion:

Titrate infusion according to procedure outlined in Usual Dose.

ACTIONS

A short-acting, B_1-selective adrenergic blocking agent with antiarrhythmic effects. Decreases HR and BP in a dose-related titratable manner. Hemodynamically similar to propranolol, but vascular resistance is not increased. Onset of action occurs within 1 to 2 minutes. Half-life is approximately 9 minutes, and the effects last about 20 to 30 minutes. Metabolized via esterases in RBCs and excreted in urine.

INDICATIONS AND USES

Management of supraventricular tachycardia (atrial fibrillation or atrial flutter) in situations requiring short-term control of ventricular rate with a short-acting agent (perioperative, postoperative, or other emergent circumstances). ■ Management of noncompensatory tachycardia when HR requires specific intervention. ■ Management of intraoperative and postoperative tachycardia and/or hypertension.

Limitation of use:

Intended only for short-term use.

CONTRAINDICATIONS

Cardiogenic shock. ■ Decompensated heart failure. ■ Heart block greater than first degree. ■ Hypersensitivity reactions, including anaphylaxis, to esmolol or any of its inactive ingredients (cross-sensitivity between beta-blockers is possible). ■ IV administration of cardiodepressant calcium-channel antagonists (e.g., verapamil) and esmolol in close proximity (i.e., while the cardiac effects of the other drug are still present). ■ Pulmonary hypertension. ■ Severe sinus bradycardia. ■ Sick sinus syndrome.

PRECAUTIONS

For IV use only. ■ May cause hypotension at any dose but is dose related; risk is increased in patients with hemodynamic compromise, in patients receiving interacting medications, and with doses above 200 mcg/kg/min. Severe reactions may include loss of consciousness, cardiac arrest, and death. ■ Use caution in patients with first-degree AV block, sinus node dysfunction, or conduction disorders. May be at increased risk for bradycardia. Sinus pause, heart block, severe bradycardia, and cardiac arrest have occurred. ■ May further depress cardiac contractility and precipitate heart failure and cardiogenic shock. ■ Use caution in patients whose BP is primarily driven by vasoconstriction associated with hypothermia (e.g., intraoperative and postoperative tachycardia and hypertension). ■ Use with extreme caution in patients with reactive airway disease (e.g., asthma), diabetes mellitus and/or hypoglycemia, Prinzmetal's angina, pheochromocytoma, hypovolemia, peripheral circulatory disorders (Raynaud's disease, peripheral occlusive vascular disease), coronary artery disease, impaired renal function, metabolic acidosis, and hyperthyroidism. ■ In general, patients with reactive airway disease (e.g., asthma) should not receive beta-blockers. Titrate to the lowest possible effective dose. ■ In patients with hypoglycemia or diabetes who are receiving insulin or hypoglycemic agents, beta-blockers may mask tachycardia of hypoglycemia, but other manifestations of hypoglycemia such as dizziness and sweating may still be observed. ■ May exacerbate angina attacks in patients with Prinzmetal's angina; do not use nonselective beta-blockers (e.g., propranolol). ■ A paradoxical increase in BP may occur if beta-blockers are administered to patients with pheochromocytoma. If use is necessary, administer an alpha-blocker (e.g., phentolamine) before the beta-blocker. ■ Can worsen reflex tachycardia and increase the risk of hypotension in hypovolemic patients. ■ May increase serum potassium levels, causing hyperkalemia. Risk is increased in patients with renal impairment and is potentially life threatening in hemodialysis patients. ■ Use caution in patients with metabolic acidosis; hyperkalemic renal tubular acidosis has been reported. ■ Beta-adrenergic blockade may mask the clinical signs of hyperthyroidism (e.g., tachycardia). Abrupt withdrawal may precipitate thyroid storm. ■ Patients at risk for hypersensitivity reactions may be more reactive to allergen exposure when receiving beta-blockers and may be unresponsive to the usual doses of epinephrine used to treat anaphylactic or anaphylactoid reactions; see Drug/Lab Interactions. ■ Infusion site reactions, including irritation, inflammation, and severe reactions (e.g., thrombophlebitis, necrosis, and blistering), have occurred; avoid infusion into small veins or through a butterfly catheter. ■ Although it has not been a problem with esmolol, it is recommended that the dose of beta-adrenergic blockers be reduced gradually to avoid rebound angina, MI, or ventricular arrhythmias. Use caution, especially in patients with coronary artery disease. ■ Intended for short-term use only. Transfer to an alternative antiarrhythmic agent (e.g., digoxin, verapamil) is required after stable clinical status and HR control are obtained; see Usual Dose. ■ See Drug/Lab Interactions, Monitor, and Antidote.

Monitor:

Continuous observation of the patient and ECG and BP monitoring are mandatory during administration. Hypotension should reverse within 30 minutes after decreasing the infusion rate or discontinuing the drug. ■ Avoid infusion into small veins or through a butterfly catheter. Well tolerated if administered through a central vein. Monitor for infusion site reaction and prevent extravasation. Restart at an alternate infusion site. ■ Titrate BP slowly in patients whose BP is primarily driven by vasoconstriction associated with hypothermia (e.g., intraoperative and postoperative tachycardia and hypertension). ■ May mask symptoms of hypoglycemia; monitor blood glucose in patients with diabetes. ■ Monitor electrolytes as indicated. Monitor patients with increased risk factors very closely; see Precautions. ■ See Drug/Lab Interactions and Contraindications.

Maternal/Child:

Category C: safety for use in pregnancy not established. Use only when clearly indicated. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies are insufficient to determine if the elderly respond differently from younger subjects. Consider age-related organ impairment (e.g., bone marrow reserve, renal, hepatic); monitor and reduce dose if indicated.

DRUG/LAB INTERACTIONS

The effects of esmolol on BP, contractility, and impulse propagation can be increased with concomitant use of other drugs that can lower BP, reduce myocardial contractility, or interfere with sinus node function or electrical impulse propagation in the myocardium. May result in severe hypotension, cardiac failure, severe bradycardia, sinus pause, sinoatrial block, atrioventricular block, and/or cardiac arrest. ■ **Sympathomimetic drugs having beta-adrenergic agonist activity** (e.g., epinephrine, norepinephrine) will counteract the effects of esmolol. ■ Use with **calcium channel blockers** may potentiate both drugs and result in severe depression of myocardium and AV conduction, severe hypotension, and fatal cardiac arrest. ■ Increases **digoxin** blood levels, synergistic with digoxin; both drugs slow AV conduction. Concomitant use increases the risk of bradycardia. ■ Esmolol should not be used in patients receiving **vasoconstrictive or inotropic drugs** (e.g., norepinephrine, digoxin) because of the potential for reduced cardiac contractility when the systemic vascular resistance is high. ■ Concomitant use with certain **antihypertensive agents** (e.g., clonidine, guanfacine) may precipitate increased withdrawal effects (withdrawal rebound hypertension). If antihypertensive therapy is to be interrupted or discontinued, discontinue the beta-blocker first and then gradually discontinue the antihypertensive agent. ■ Concomitant use with **catecholamine-depleting drugs** (e.g., reserpine) may produce additive effects. Monitor for hypotension and bradycardia. ■ May prolong neuromuscular blockade produced by **succinylcholine** and moderately prolong neuromuscular blockade produced by **mivacurium**. ■ May mask S/S of developing hypoglycemia in patients on **insulin or oral antidiabetic agents.** ■ Concurrent use with **xanthines** (e.g., aminophylline, theophyllines) may result in mutual inhibition of therapeutic effects. ■ Patients taking **beta-blockers** who are exposed to a potential allergen may be unresponsive to the usual dose of epinephrine used to treat a hypersensitivity reaction.

SIDE EFFECTS

Symptomatic hypotension (dizziness, excessive sweating) and asymptomatic hypotension are most common. Inflammation or induration of the infusion site, nausea, and somnolence are also fairly common. Abdominal discomfort, abnormal thinking, agitation, anxiety, confusional state, constipation, convulsions (with one death), depression, dry mouth, dyspepsia, flushing, headache, light-headedness, pallor, paresthesia, peripheral ischemia, speech disorders, syncope, urinary retention, and vomiting have occurred.

Overdose:

Cardiac effects (e.g., atrioventricular block [first-, second-, third-degree], bradycardia, cardiac failure [including cardiogenic shock], cardiac arrest/asystole, decreased cardiac contractility, hypotension, intraventricular conduction delays, junctional rhythms, and pulseless electrical activity); CNS effects (e.g., fatigue, lethargy, respiratory depression, seizures, sleep and mood disturbances, and coma). In addition, bronchospasm, hyperkalemia, hypoglycemia (especially in children), mesenteric ischemia, and peripheral cyanosis may occur.

Post-Marketing:

Angioedema, cardiac arrest, coronary arteriospasm, psoriasis, urticaria.

ANTIDOTE

Notify the physician of all side effects. Decrease rate or discontinue drug if hypotension occurs. Hypotension should reverse within 30 minutes. Trendelenburg position may be appropriate. May require treatment with IV fluids or vasopressors (e.g., dopamine, norepinephrine [Levophed]), but protracted severe hypotension may result. Unresponsive hypotension and bradycardia may be reversed by glucagon 5 to 10 mg over 30 seconds followed by a continuous infusion of 5 mg/hr. Reduce rate as condition improves. Decrease rate of or discontinue esmolol if severe bradycardia develops. Treat with an anticholinergic drug (e.g., atropine) or cardiac pacing. Discontinue esmolol at the first S/S of cardiac failure and start supportive treatment (e.g., digoxin and diuretics). In shock resulting from inadequate cardiac contractility, consider IV dobutamine or dopamine. Glucagon may be useful. Discontinue the infusion if bronchospasm occurs. Administer a beta$_2$-stimulating agent (e.g., epinephrine, albuterol) and/or a theophylline derivative and monitor ventricular rate. Treat other side effects symptomatically and resuscitate as necessary.

ESOMEPRAZOLE SODIUM

(es-oh-**MEP**-rah-zohl **SO**-dee-um)
Nexium IV
Proton pump inhibitor (PPI) (gastric acid inhibitor)
Substituted benzimidazole
pH 9 to 11

USUAL DOSE

Gastroesophageal reflux disease (GERD) with erosive esophagitis:

Given as an alternative to oral therapy. Resume oral therapy as soon as practical. Safety and efficacy of IV use for more than 10 days not established. Dose and serum levels similar by IV or oral route.

Adults:

20 or 40 mg as an IV injection or infusion once daily for up to 10 days.

Risk reduction of rebleeding gastric or duodenal ulcers following therapeutic endoscopy in adults:

80 mg as an IV infusion over 30 minutes followed by a continuous infusion of 8 mg/hr for 71.5 hours (a total treatment duration of 72 hours). Therapy is for management of the acute initial bleeding of gastric or duodenal ulcers and does not constitute full treatment. Follow with oral acid-suppressive therapy.

PEDIATRIC DOSE

GERD with erosive esophagitis:

Administered as an infusion over 10 to 30 minutes. See comments under Usual Dose.

1 to 17 years of age:

Weight less than 55 kg: 10 mg. **Weight 55 kg or more:** 20 mg.

1 month to less than 1 year of age:

0.5 mg/kg.

DOSE ADJUSTMENTS

GERD with erosive esophagitis:

No dose adjustment is required based on age or gender, in the elderly, in patients with renal insufficiency, or in patients with mild to moderate liver impairment (Child-Pugh Classes A and B). ■ Do not exceed a dose of 20 mg in patients with severe liver impairment (Child-Pugh Class C [10 or over]).

Risk reduction of rebleeding gastric or duodenal ulcers following therapeutic endoscopy in adults:

No adjustment of the initial 80-mg dose is required. Reduce the continuous infusion rate to a maximum of 6 mg/hr for patients with mild to moderate liver impairment (Child-Pugh Classes A and B) and to a maximum of 4 mg/hr for patients with severe liver impairment (Child-Pugh Class C). Do not exceed these maximum doses.

DILUTION

GERD with erosive esophagitis:

Injection (adults):

Each 40-mg vial must be reconstituted with 5 mL of NS. Mix gently until powder is dissolved.

Infusion (adult and pediatric patients 1 month to less than 1 year of age):

To determine the dose needed for patients 1 month to less than 1 year of age, first calculate the dose (0.5 mg/kg). Reconstitute a 40-mg vial with 5 mL of NS, D5W, or LR. Further dilute to a final volume of 50 mL with NS. Withdraw desired dose to administer as an infusion.

40-MG vial:

Concentration is 0.8 mg/mL; withdraw 25 mL for a 20-mg dose and 12.5 mL for a 10-mg dose. Adjust infusion amount as needed to provide the correct dose (0.5 mg/kg) for pediatric patients 1 month to less than 1 year of age.

Risk reduction of rebleeding gastric or duodenal ulcers following therapeutic endoscopy in adults:

30-minute infusion:

Two 40-mg vials required for the 80-mg dose. Reconstitute each 40-mg vial with 5 mL of NS and add contents of both vials to 100 mL of NS.

Continuous infusion:

Two 40-mg vials required. Reconstitute each 40-mg vial with 5 mL of NS and add contents of both vials to 100 mL of NS. Administer at a rate of 8 mg/hr for 71.5 hours; see Dose Adjustments.

Filters:

Not required or recommended; no additional data available from manufacturer.

Storage:

Before use, store in carton at CRT and protect from light. Reconstituted and diluted solutions may be stored at CRT. Administer reconstituted solutions within 12 hours of reconstitution. Administer diluted solutions within 6 hours if diluted in D5W and within 12 hours if diluted in NS or LR. Discard any unused solution.

COMPATIBILITY

Manufacturer states, “Should not be administered concomitantly with any other medications through the same IV site and/or tubing.” Flush the IV line with a **compatible** IV solution (NS, LR, or D5W) before and after administration of esomeprazole.

RATE OF ADMINISTRATION

Flush the IV line with a **compatible** IV solution (NS, LR, or D5W) before and after administration of esomeprazole.

GERD with erosive esophagitis:

Injection (adults):

A single 20- or 40-mg dose evenly distributed over no less than 3 minutes.

Infusion (adults and pediatric patients):

A single dose properly diluted as an infusion and evenly distributed over 10 to 30 minutes.

Risk reduction for rebleeding of gastric or duodenal ulcers following therapeutic endoscopy in adults:

Initial dose:

A single 80-mg dose evenly distributed over 30 minutes.

Continuous infusion:

Administer at a rate of 8 mg/hr over 71.5 hours; see Dose Adjustments.

ACTIONS

A proton pump inhibitor. It suppresses gastric acid secretion by specific inhibition of the H^+/K^+-ATPase in the gastric parietal cell. It blocks the final step in acid production, thus reducing gastric acidity. Effect is dose-related. Highly bound to serum protein. Extensively metabolized in the liver by the cytochrome P_{450} isoenzyme system (CYP2C19 and CYP3A4 isoenzymes). Half-life is 1.1 to 1.4 hours and is prolonged with increasing doses. Primarily excreted as metabolites in urine with some excretion in feces. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of GERD with erosive esophagitis in adults and pediatric patients 1 month to 17 years of age. Used as an alternative to oral therapy when oral esomeprazole is not possible or appropriate. ■ Risk reduction for rebleeding in patients following therapeutic endoscopy for acute bleeding gastric or duodenal ulcers in adults.

CONTRAINDICATIONS

Known hypersensitivity to esomeprazole (Nexium) or other substituted benzimidazoles (e.g., omeprazole [Prilosec], pantoprazole [Protonix]) or to any component of the formulation. ■ Contraindicated in patients receiving rilpivirine-containing products (e.g., systemic rilpivirine, emtricitabine/rilpivirine).

PRECAUTIONS

For IV use only; do not give IM or SC. ■ Discontinue as soon as the patient is able to resume oral therapy. ■ Gastric malignancy may be present even though patient's symptoms improve. Consider additional follow-up and diagnostic testing in adult patients who have a suboptimal response or an early symptomatic relapse after completing treatment with a PPI. In older patients, also consider an endoscopy. ■ Decreased gastric acidity may increase bacterial count in GI tract. Risk of GI infections (e.g., *Salmonella* and *Campylobacter*) may be slightly increased. ■ May be associated with an increased risk of *Clostridium difficile*–associated diarrhea (CDAD), especially in hospitalized patients. Consider in patients who develop diarrhea that does not improve. ■ May be associated with an increased risk for osteoporosis-related fractures of the hip, wrist, or spine. Risk increased in patients receiving high-dose (multiple daily doses) and long-term therapy (a year or longer). Use lowest dose and shortest duration of therapy appropriate for the condition being treated. ■ Cutaneous lupus erythematosus (CLE) and systemic lupus erythematosus (SLE) have been reported in patients taking PPIs. These events have occurred as both new onset and as an exacerbation of existing autoimmune disease. Subacute CLE is more common and occurs weeks to years after continuous PPI therapy in patients ranging from infants to the elderly. In general, histologic findings were observed without organ involvement. PPI-induced systemic lupus erythematosus (SLE) is usually milder than non–drug-induced SLE and occurs days to years after initiating PPI therapy, primarily in patients ranging from young adults to the elderly. Most patients present with rash, but arthralgia and cytopenia have also been reported. Discontinue esomeprazole if S/S of CLE or SLE develop, and refer patient to the appropriate specialist. Most patients improve within 4 to 12 weeks of PPI discontinuation. ■ Hypomagnesemia, both symptomatic and asymptomatic, has been reported rarely (usually with the use of PPIs for 3 months to more than a year). Arrhythmias, seizures, and tetany have occurred. Magnesium replacement and discontinuation of esomeprazole may be required. ■ Patients should use the lowest dose and shortest duration of PPI therapy appropriate for the condition being treated. ■ Acute interstitial nephritis has been observed. Is generally attributed to an idiopathic hypersensitivity reaction and may occur at any time during therapy. Discontinue esomeprazole if it occurs. ■ PPI use is associated with an increased risk of fundic gland polyps that increases with long-term use, especially beyond 1 year. Most patients were asymptomatic and polyps were identified incidentally on endoscopy. ■ To avoid complications, use the shortest duration of PPI therapy appropriate to the condition being treated. ■ See Drug/Lab Interactions.

Monitor:

Observe for S/S of a hypersensitivity reaction (e.g., anaphylaxis, anaphylactic shock, angioedema, bronchospasm, acute interstitial nephritis, urticaria). ■ Monitor vital signs, pain levels, and injection site. ■ Consider obtaining baseline and periodic magnesium levels if prolonged therapy is indicated or in patients taking digoxin or medications that may cause hypomagnesemia (e.g., diuretics). ■ Serologic testing (e.g., antinuclear antibody [ANA] titers) may be indicated in patients who present with S/S of CLE or SLE.

Patient Education:

Review prescription and nonprescription drugs with physician. ■ Oral route preferred. ■ Promptly report cardiovascular or neurologic symptoms, including dizziness, palpitations, seizures, or tetany; may be signs of hypomagnesemia.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Esomeprazole may be secreted in human milk; use with caution during breast-feeding. ■ Safety and effectiveness for use of IV formulation for short-term treatment of GERD with erosive esophagitis in pediatric patients established for ages 1 month to 17 years. Safety and effectiveness for use in neonates (0 to 1 month of age) not established.

Elderly:

Safety and effectiveness similar to that seen in younger adults. ■ Consider potential for impaired liver function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Extensively metabolized by CYP2C19 and CYP3A4. ■ Because of profound and long-lasting inhibition of gastric acid secretion, esomeprazole may interfere with the absorption of drugs in which gastric pH is an important determinant of their bioavailability. Absorption of **atazanavir, erlotinib, iron salts, ketoconazole**, and **mycophenolate mofetil** can decrease; other drugs (e.g., digoxin) can increase. Monitor digoxin concentrations and adjust the dose, if needed, to maintain therapeutic drug concentrations. ■ Avoid concurrent use with **clopidogrel**; esomeprazole may interfere with the conversion of clopidogrel into its active form and decrease its effectiveness. ■ Exposure of **citalopram** is increased, leading to an increased risk of QT prolongation. Limit the dose of citalopram to a maximum of 20 mg/day.

Coadministration of **mycophenolate mofetil** and **omeprazole** in transplant patients receiving MMF reduces the exposure to MMF's active metabolite, mycophenolic acid; see Precautions. ■ Increases in INR and PT have been reported when administered concurrently with **warfarin;** monitoring of INR and PT indicated. ■ Concurrent use with **selected protease inhibitors** such as atazanavir and nelfinavir is not recommended. Coadministration of proton pump inhibitors results in a significant reduction in plasma concentrations of atazanavir and nelfinavir, thus inhibiting their antiviral therapeutic effect and promoting the development of drug resistance. In contrast, elevated plasma concentrations have been reported with **other protease inhibitors** (e.g., saquinavir); dose reduction of saquinavir should be considered. Unchanged serum levels have been reported with some other antiretroviral drugs. ■ The metabolism of **diazepam** may be decreased and serum levels increased by esomeprazole; not considered clinically significant. ■ Administration with a **combined inhibitor of CYP2C19 and CYP3A4** (e.g., voriconazole) may more than double the exposure (concentration) of esomeprazole. With recommended doses of esomeprazole, a dose adjustment is not normally required; however, it may be indicated in patients who require higher doses. ■ Concurrent administration of **oral contraceptives, diazepam, phenytoin, or quinidine** did not change the pharmacokinetic profile of esomeprazole. ■ Drugs that **induce CYP2C19 or CYP3A4** (e.g., rifampin, St. John's wort) can substantially decrease esomeprazole concentrations. Avoid concomitant use. ■ Concomitant administration of esomeprazole and **tacrolimus** may increase serum levels of tacrolimus. Monitoring of serum levels may be indicated. ■ Studies suggest no clinically significant interactions with other drugs metabolized by the cytochrome P_{450} system (e.g., amoxicillin, clarithromycin, phenytoin, quinidine). ■ Coadministration with **cilostazol** may increase concentrations of cilostazol and its metabolite. Consider a dose reduction of cilostazol from 100 mg to 50 mg twice daily. ■ Concomitant use of proton pump inhibitors with high-dose **methotrexate** may elevate and prolong serum levels of methotrexate and/or its metabolite. May lead to methotrexate toxicity; consider withdrawal of esomeprazole. ■ Serum chromogranin A (CgA) levels increase secondary to drug-induced decreases in gastric acidity. Increased CgA levels may cause a false-positive result in diagnostic tests for neuroendocrine tumors. Temporarily discontinue esomeprazole at least 14 days before assessing CgA levels, and consider repeating the test (using the same commercial laboratory) if the initial CgA level is high.

SIDE EFFECTS

Generally well tolerated. The most commonly reported side effects include abdominal pain, constipation, diarrhea, dizziness/vertigo, dry mouth, flatulence, headache, injection site pain or reaction (including erythema, phlebitis, superficial phlebitis, swelling, and thrombophlebitis), nausea, and pruritus. Cough, duodenal ulcer hemorrhage, and fever were also reported. Numerous other side effects may occur in fewer than 1% of patients.

Post-Marketing:

Aggression, agitation, agranulocytosis, alopecia, anaphylaxis (rare), blurred vision, bone fracture, bronchospasm, CDAD, CLE, depression, GI candidiasis, gynecomastia, hallucinations, hepatic encephalopathy, hepatic failure, hepatitis with or without jaundice (rare), hyperhidrosis, hypomagnesemia with or without hypocalcemia and/or hypokalemia, interstitial nephritis, microscopic colitis, muscular weakness, myalgia, pancreatitis, pancytopenia, serious dermatologic reactions (including erythema multiforme, photosensitivity, Stevens-Johnson syndrome, and toxic epidermal necrolysis [some fatal]), shock, SLE, stomatitis, and taste disturbance.

Overdose:

Ataxia, changes in respiratory frequency, decreased motor activity, intermittent clonic convulsions, tremor.

ANTIDOTE

Keep physician informed of all side effects. May be treated symptomatically. If hypomagnesemia develops, magnesium replacement and discontinuation of esomeprazole may be required. Discontinue esomeprazole if acute interstitial nephritis, CLE, or SLE occurs. Discontinue and initiate appropriate treatment if hypersensitivity reactions, S/S associated with post-marketing reports, or overdose occurs; see Side Effects. Not removed by hemodialysis.

ETELCALCETIDE

(e-tel-**KAL**-se-tide)
Parsabiv
Calcimimetic agent
pH 3.3

USUAL DOSE

Pretreatment:

Ensure corrected serum calcium is at or above the lower limit of normal before initiating dosing, before a dose increase, or before re-initiation after a dosing interruption. ***DO NOT*** initiate in patients if the corrected serum calcium is less than the lower limit of normal; see Monitor.

Etelcalcetide:

Initial dose:

5 mg as an IV bolus injection 3 times a week at the end of hemodialysis treatment.

Maintenance dose:

Individualized and determined by titration based on parathyroid hormone (PTH) and corrected serum calcium response. This is the dose that maintains PTH levels within the recommended target range and corrected serum calcium within the normal range. Range of the maintenance dose from lowest to highest is 2.5 mg 3 times a week to 15 mg 3 times a week. See Dose Adjustments.

Switching from cinacalcet (Sensipar) to etelcalcetide:

Discontinue cinacalcet for at least 7 days before starting etelcalcetide, and begin etelcalcetide dosing at 5 mg. Ensure corrected serum calcium is at or above the lower limit of normal before beginning etelcalcetide.

DOSE ADJUSTMENTS

DO NOT administer any missed doses if a regularly scheduled hemodialysis treatment is missed. Resume etelcalcetide at the prescribed dose at the end of the next hemodialysis treatment. If doses are missed for more than 2 weeks, re-initiate at the starting dose of 5 mg (or 2.5 mg if that was the patient's last dose). ■ If corrected serum calcium is within the normal range and PTH levels are above the recommended target range, increase the etelcalcetide dose in 2.5- or 5-mg increments based on the patient's PTH levels no more frequently than every 4 weeks up to a maximum dose of 15 mg 3 times a week. ■ If PTH levels are below the target range, decrease or temporarily discontinue etelcalcetide. ■ If the corrected serum calcium is below the lower limit of normal but at or above 7.5 mg/dL and without symptoms of hypocalcemia, consider decreasing or temporarily discontinuing etelcalcetide. Alternately, concomitant therapies may be used to increase corrected serum calcium. If the dose is stopped, re-initiate at a lower dose when the PTH is within the target range and hypocalcemia has been corrected. ■ Stop etelcalcetide and treat hypocalcemia if the corrected serum calcium falls below 7.5 mg/dL or if symptoms of hypocalcemia appear (muscle spasms, myalgias, paresthesias, QT interval prolongation, ventricular arrhythmia). When the corrected serum calcium is within normal limits, symptoms of hypocalcemia have resolved, and predisposing factors for hypocalcemia have been addressed, re-initiate etelcalcetide at a dose 5 mg lower than the last administered dose. If the last dose was 2.5 mg or 5 mg, re-initiate at a dose of 2.5 mg.

DILUTION

A clear, colorless solution available in single-dose vials containing 2.5 mg/0.5 mL, 5 mg/mL, and 10 mg/2 mL. Ready to use. Do not mix or dilute before administration.

Filters:

Specific information not available.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. After removal from refrigeration, do not expose to temperatures above 25° C (77° F). Use within 7 days if stored in original carton. Use within 4 hours and do not expose to direct sunlight if removed from original carton.

COMPATIBILITY

Manufacturer states, "Do not mix or dilute before administration."

RATE OF ADMINISTRATION

Administer as an IV bolus injection into the venous line of the dialysis circuit at the end of the hemodialysis treatment during rinse back or intravenously after rinse back.

ACTIONS

A synthetic peptide calcium-sensing receptor agonist. A calcimimetic agent that binds to the calcium-sensing receptor (CaSR) and enhances activation of the receptor by extracellular calcium. Activation of the CaSR on parathyroid chief cells decreases PTH secretion. Reductions in PTH levels are dose dependent and decrease within 30 minutes, resulting in reductions in calcium and attenuation of postdialytic phosphate elevation. Effects are maintained with dosing 3 times a week. Some binding to plasma albumin. Effective half-life is approximately 3 to 4 days. Cleared by renal excretion; hemodialysis is the predominant elimination pathway in chronic kidney disease patients requiring hemodialysis.

INDICATIONS AND USES

Treatment of secondary hyperparathyroidism (HPT) in adult patients with chronic kidney disease (CKD) undergoing hemodialysis.

Limitation of use:

Has not been studied in adult patients with parathyroid carcinoma or primary hyperparathyroidism or in patients with CKD not undergoing hemodialysis. Etelcalcetide is not recommended in these populations.

CONTRAINDICATIONS

Known hypersensitivity to etelcalcetide or any of its excipients.

PRECAUTIONS

Lowers serum calcium; can lead to hypocalcemia, which may be severe. S/S of hypocalcemia include muscle spasms, myalgias, paresthesias, seizures, QT interval prolongation, and ventricular arrhythmias. ■ QT prolongation and ventricular arrhythmias have occurred. Patients with congenital long QT syndrome, history of QT interval prolongation, family history of long QT syndrome or sudden cardiac death, and other conditions that predispose to QT interval prolongation and ventricular arrhythmias may be at increased risk if they develop hypocalcemia. ■ Significant reductions in corrected serum calcium may lower the threshold for seizures. Patients with a history of a seizure disorder may be at increased risk for seizures if they develop hypocalcemia. ■ Concurrent administration with another oral calcium-sensing receptor agonist (e.g., cinacalcet [Sensipar]) could result in severe, life-threatening hypocalcemia; see Usual Dose and Drug/Lab Interactions. ■ Hypotension, congestive heart failure, and decreased myocardial performance have been reported. ■ Upper GI bleeding has occurred. Etiology and relation to etelcalcetide is unclear. Patients with risk factors for upper GI bleeding may be at increased risk for GI bleeding while receiving etelcalcetide. ■ If PTH levels are chronically suppressed, adynamic bone disease may develop. Adynamic bone disease is a variety of renal osteodystrophy characterized by reduced osteoblasts and osteoclasts, no accumulation of osteoid, and markedly low bone turnover. ■ Hypersensitivity reactions, including facial edema, pruritic rash, and urticaria have occurred. ■ As with all peptide therapeutics, there is a potential for immunogenicity.

Monitor:

Obtain baseline corrected serum calcium and PTH before dose initiation or dose adjustment. Monitor corrected serum calcium 1 week after dose initiation or dose adjustment and every 4 weeks during maintenance therapy. Monitor PTH levels 4 weeks after dose initiation or dose adjustment and per clinical practice during maintenance therapy. ■ Monitor corrected serum calcium and QT interval closely in patients at risk for QT prolongation and ventricular arrhythmias. ■ Monitor corrected serum calcium closely in patients with seizure disorders. ■ If corrected serum calcium falls below the lower limit of normal or symptoms of hypocalcemia develop, start or increase calcium supplementation (including calcium, calcium-containing phosphate binders, and/or vitamin D sterols or increases in dialysate calcium concentration). Dose reduction or discontinuation may be necessary. ■ Closely monitor for worsening signs and symptoms of heart failure. ■ Closely monitor patients with risk factors for upper GI bleeding (e.g., known gastritis, esophagitis, ulcers, or severe vomiting). ■ To avoid adynamic bone disease, reduce the dose of vitamin D sterols and/or etelcalcetide or discontinue etelcalcetide if PTH levels decrease below the recommended target range. Resume therapy at a lower dose to maintain PTH levels in the target range; see Dose Adjustments. ■ Monitor for S/S of a hypersensitivity reaction (e.g., facial edema, pruritic rash, and urticaria).

Patient Education:

Report S/S of hypocalcemia, including muscle spasms, myalgias, paresthesias, and seizures. ■ Report symptoms of GI bleeding. ■ Additional monitoring may be needed in patients with CHF. ■ Regular blood testing is imperative to monitor safety and effectiveness of therapy. ■ Breast-feeding is not recommended.

Maternal/Child:

No available data on the use of etelcalcetide in pregnant women. Use during pregnancy only if clearly needed. ■ Breast-feeding is not recommended. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No clinically significant differences in safety or effectiveness observed between elderly patients and other age-groups.

DRUG/LAB INTERACTIONS

Concurrent administration of etelcalcetide with another oral calcium-sensor receptor agonist could result in severe, life-threatening hypocalcemia. Patients switching from **cinacalcet** (Sensipar) to etelcalcetide should discontinue cinacalcet for at least 7 days before starting etelcalcetide and then begin etelcalcetide dosing at 5 mg. Ensure that corrected serum calcium is at or above the lower limit of normal before beginning etelcalcetide.

SIDE EFFECTS

Blood calcium decrease, diarrhea, headache, hypocalcemia, muscle spasms, nausea, paresthesia, and vomiting are the most common adverse reactions. Adynamic bone disease, CHF, hypersensitivity reactions, hypophosphatemia, myalgia, QTc interval prolongation secondary to hypocalcemia, and upper GI bleeding have also been reported and can be serious.

ANTIDOTE

Notify the physician of side effects. Treatment should consist of general supportive measures and determination of corrected serum calcium and PTH levels. ■ If PTH levels are below the target range, decrease or temporarily discontinue etelcalcetide. ■ If the corrected serum calcium is below the lower limit of normal but at or above 7.5 mg/dL without symptoms of hypocalcemia, consider decreasing or temporarily discontinuing etelcalcetide. Alternately, concomitant therapies may be used to increase corrected serum calcium. If the dose is stopped, then re-initiate at a lower dose when the PTH is within the target range and hypocalcemia has been corrected. ■ Stop etelcalcetide and treat hypocalcemia if the corrected serum calcium falls below 7.5 mg/dL or if symptoms of hypocalcemia appear (muscle spasms, myalgias, paresthesias, QT interval prolongation, ventricular arrhythmia). When the corrected serum calcium is within normal limits, symptoms of hypocalcemia have resolved, and predisposing factors for hypocalcemia have been addressed, re-initiate etelcalcetide at a dose 5 mg lower than the last administered dose. If the last dose was 2.5 mg or 5 mg, re-initiate at a dose of 2.5 mg. Treat hypersensitivity reactions as indicated. There is no clinical experience with overdosage. In the event of an overdose, obtain corrected serum calcium and monitor for symptoms of hypocalcemia. Treat as indicated. Etelcalcetide is removed by dialysis, but hemodialysis has not been studied as a treatment for overdose.

ETEPLIRSEN

(e-**TEP**-lir-sen)
Exondys 51
Antisense oligonucleotide
pH 7.5

USUAL DOSE

Pretreatment:

Pretesting indicated; see Monitor.

Eteplirsen:

30 mg/kg administered once weekly as a 35- to 60-minute IV infusion. If a dose of eteplirsen is missed, it may be administered as soon as possible after the scheduled time. Consider application of a topical anesthetic cream to the infusion site before administration of eteplirsen.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

Eteplirsen has not been studied in patients with renal or hepatic impairment. Dosing recommendations in these patient populations have not been provided by the manufacturer.

DILUTION

Available as a 100 mg/2 mL and 500 mg/10 mL (50 mg/mL) solution in a single-dose vial. Calculate the total dose of eteplirsen administered based on the patient's weight. Determine the volume of eteplirsen needed and the correct number of vials to supply the calculated dose. Allow vials to warm to RT. Mix the contents of each vial by gently inverting the vial 2 or 3 times. ***Do not shake***. Visually inspect each vial. Eteplirsen is a clear, colorless solution that may have some opalescence. Do not use if the solution is discolored or if particulate matter is present. Withdraw the calculated volume of eteplirsen from the appropriate number of vials using a syringe fitted with a 21-gauge or smaller noncoring needle. Dilute the withdrawn eteplirsen in NS to make a total volume of 100 to 150 mL. For example, a 70-kg patient would require 2,100 mg (30 mg/kg × 70 kg = 2,100 mg). 2,100 mg ÷ 50 mg/mL = 42 mL. Warm four 500 mg/10 mL vials and one 100 mg/2 mL vial to RT and further dilute in 100 mL of NS.

Storage:

Store unopened vials in original carton at 2° to 8° C (36° to 46° F). Protect from light. Do not freeze. Immediate use preferred. Complete infusion of diluted solution within 4 hours of dilution. If immediate use is not possible, the diluted solution may be stored for up to 24 hours at 2° to 8° C (36° to 46° F). Discard unused eteplirsen.

COMPATIBILITY

Manufacturer states, "Do not mix other medications with eteplirsen or infuse other medications concomitantly via the same intravenous access line."

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 35 to 60 minutes. Flush the intravenous access line with NS before and after the eteplirsen infusion. If a hypersensitivity reaction occurs, consider slowing the infusion or interrupting the eteplirsen therapy.

ACTIONS

Duchenne's muscular dystrophy (DMD) is a rare progressive disease characterized by the virtual absence of functional dystrophin, a protein essential for maintaining muscle cell membrane integrity. Eteplirsen is an antisense oligonucleotide of the phosphorodiamidate morpholino oligomer (PMO) subclass. PMOs are synthetic molecules in which the five-membered ribofuranosyl rings found in natural DNA and

RNA are replaced by a six-membered morpholino ring. Eteplirsen is designed to bind to exon 51 of dystrophin pre-mRNA, resulting in exclusion of this exon during mRNA processing in patients with genetic mutations that are amenable to exon 51 skipping. Exon skipping is intended to allow for production of an internally truncated but functional dystrophin protein. The peak plasma concentration of eteplirsen occurs near the end of infusions following single or multiple IV infusions. Plasma protein binding is low. Eteplirsen does not appear to be metabolized by hepatic microsomes. Renal clearance of eteplirsen accounts for approximately two thirds of the administered dose within 24 hours of IV administration. The elimination half-life of eteplirsen is 3 to 4 hours.

INDICATIONS AND USES

Treatment of Duchenne's muscular dystrophy (DMD) in patients who have confirmed mutation of the DMD gene that is amenable to exon 51 skipping. ■ This indication is approved under accelerated approval based on an increase in dystrophin in skeletal muscle observed in some patients treated with eteplirsen. A clinical benefit of eteplirsen has not been established. Continued approval for this indication may be contingent on verification of a clinical benefit in confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

Hypersensitivity reactions have occurred.

Monitor:

Confirmation of mutation of the DMD gene that is amenable to exon 51 skipping indicated. ■ Monitor for S/S of any adverse reactions; treat as indicated. ■ Monitor for S/S of a hypersensitivity reaction (bronchospasm, cough, dyspnea, flushing, hypotension, rash, and urticaria).

Patient Education:

Report any S/S of a hypersensitivity reaction (e.g., itching, rash, wheezing) and/or changes in balance.

Maternal/Child:

Eteplirsen has not been studied in females. There are no human or animal data available to assess eteplirsen during pregnancy. ■ There are no human or animal data available to assess the effect of eteplirsen on milk production, the presence in milk, or the effects of eteplirsen on the breast-fed infant. ■ DMD is largely a disease of children and young adults. Approved indication includes use in pediatric patients.

Elderly:

DMD is largely a disease of children and young adults; therefore there is no geriatric experience with eteplirsen.

DRUG/LAB INTERACTIONS

Based on in vitro data on plasma protein binding, CYP or drug transporter interactions, and microsomal metabolism, eteplirsen is expected to have a low potential for drug-drug interactions in humans.

SIDE EFFECTS

The most common adverse reactions were balance disorder and vomiting. Other adverse reactions (reported in 10% or more of patients) were arthralgia, catheter site pain, contact dermatitis, contusion, excoriation, rash, and upper respiratory tract infection. Hypersensitivity reactions have also occurred.

ANTIDOTE

Notify physician of any side effects; treat as indicated. If a hypersensitivity reaction occurs, based on severity, institute appropriate medical treatment and/or consider slowing the infusion or interrupting the eteplirsen therapy. There is no experience with overdose of eteplirsen.

ETHACRYNIC ACID

(eth-ah-**KRIH**-nik **AS**-id)
Sodium Edecrin
Diuretic (Loop)
pH 6.3 to 7.7

USUAL DOSE

Regulate dose carefully to prevent a more rapid or substantial loss of fluid or electrolytes than is indicated or necessary. Diuresis and natriuresis are dependent on the degree of fluid accumulation in the patient. Potassium excretion is determined in large measure by the presence and magnitude of aldosteronism.

0.5 to 1 mg/kg of body weight. 50 mg for the average adult. A single dose not exceeding 100 mg has been used in critical situations. One dose is usually sufficient; however, a second dose may be given at an alternate IV site if indicated.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established; see Contraindications and Maternal/Child.

Unlabeled:

1 mg/kg of body weight; do not exceed adult dose.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for age-related impaired organ function and concomitant disease or drug therapy.

DILUTION

Reconstitute each 50 mg with 50 mL NS. D5W may be used if pH is above 5. D5W solutions with a pH at or below 5 may result in a hazy or opalescent solution; do not use. Do not add to IV solutions. May be given through the Y-tube or three-way stopcock of a running infusion or by direct IV injection.

Storage:

Store vials at CRT. Discard reconstituted solution in 24 hours.

COMPATIBILITY

Manufacturer lists whole blood or its derivatives, solutions or drugs with a final pH below 5, and Normosol M.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 10 mg or fraction thereof (approximately 10 mL) may be given over 1 minute.

IV infusion (preferred):

Infuse total dose slowly, evenly distributed over 20 to 30 minutes.

ACTIONS

A potent diuretic agent; the sodium salt of ethacrynic acid. Acts on the ascending limb of the loop of Henle and on the proximal and distal tubules. Water and electrolyte excretion may be increased several times over that of most other diuretic agents and can be effective in patients with significant renal insufficiency. Will produce diuresis in acidosis or alkalosis. Effective within 5 to 10 minutes; reaches peak effect in 15 to 30 minutes and may last for 2 hours. Protein binding is high. Rapidly distributed. Metabolized in the liver and primarily excreted in the urine. Does not cross the blood-brain barrier.

INDICATIONS AND USES

Treatment of edema when greater diuretic potential is required or rapid onset of diuresis is desired. ■ Edema associated with congestive heart failure, cirrhosis of the liver, and renal disease, including nephrotic syndrome. ■ Acute pulmonary edema. ■ Short-term management of ascites due to malignancy, idiopathic edema, and lymphedema. ■ Short-term management of hospitalized pediatric patients, other than infants, with congenital heart disease or nephrotic syndrome.

Unlabeled uses:

Used alone or with NS to increase renal excretion of calcium in hypercalcemia. ■ Used concomitantly with mannitol in the management of ethylene glycol poisoning and to increase bromide excretion in the management of bromide intoxication.

CONTRAINDICATIONS

Anuria. ■ Hypersensitivity to ethacrynic acid or any of its components. ■ Infants. ■ Severe, progressive renal disease with increasing azotemia and oliguria. ■ Severe watery diarrhea.

PRECAUTIONS

IV use indicated in patients unable to take oral medication or in emergency situations. For IV use only; do not use IM or SC. ■ Should be administered in a facility with adequate personnel, equipment, and supplies to monitor the patient and respond to any medical emergency. Effects are dose dependent and may result in profound electrolyte and water loss. ■ Use with caution in patients with cirrhosis of the liver, especially if they have a history of episodes of electrolyte imbalance or hepatic encephalopathy; may precipitate hepatic coma. ■ Too vigorous diuresis may induce an acute hypotensive episode. ■ Use caution in elderly cardiac patients; rapid contraction of plasma volume and hemoconcentration may result in thromboembolic episodes (e.g., CVA, pulmonary emboli), which may be fatal. ■ Use caution in patients receiving potassium-depleting steroids. ■ Use caution in patients receiving digoxin; potassium depletion may precipitate digoxin toxicity. ■ Risk of ototoxicity increased with higher doses, rapid injection, decreased renal function, or concurrent use with other ototoxic drugs; see Drug/Lab Interactions. ■ May increase glucose levels, uric acid levels, and urine output of magnesium.

Monitor:

Determine absolute patency of vein. Avoid extravasation. If a second dose is indicated, administer at an alternate site to avoid thrombophlebitis. ■ May precipitate excessive diuresis with water and electrolyte depletion. Obtain baseline electrolyte panel, CO_2, BUN, and SCr and monitor closely. ■ Monitor for S/S of fluid or electrolyte imbalance (e.g., confusion, drowsiness, dryness of mouth, hypochloremic alkalosis, hypokalemia, hyponatremia, hypotension, lethargy, muscle fatigue, muscle pain or cramps, nausea and vomiting, oliguria, restlessness, seizures, tachycardia, thirst, weakness) and replace electrolytes as necessary. Monitor serum and urine electrolytes more closely in patients who are vomiting or are receiving parenteral fluids. ■ Monitor VS closely. ■ Liberalization of salt intake and supplementation with potassium chloride may be indicated. ■ If metabolic alkalosis is anticipated, the use of potassium chloride or a potassium-sparing agent (e.g., spironolactone [Aldactone]) before and during treatment with ethacrynic acid may attenuate or prevent hypokalemia. ■ Additional monitoring is required if treatment is continued with oral ethacrynic acid after the initial IV dose of ethacrynic acid. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Hypotension may cause dizziness; request assistance with ambulation. ■ Promptly report dizziness, diarrhea, muscle weakness or cramps, nausea or vomiting. ■ May cause a decrease in potassium levels and require a supplement.

Maternal/Child:

Category B: use during pregnancy with extreme caution and only if clearly needed; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Use in infants is contraindicated; use in pediatric patients is limited and is not recommended. Most experience is with oral dosing. See Pediatric Dose.

Elderly:

Dosing should be cautious; see Dose Adjustments ■ Response similar to that seen in younger adults. ■ Consider increased sensitivity to hypotensive and electrolyte effects and increased risk of circulatory collapse or thromboembolic episodes. ■ Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Do not give simultaneously with **whole blood or its derivatives.** ■ May cause transient or permanent deafness when doses exceed the usual or when given in conjunction with **other ototoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], cisplatin [Platinol], furosemide [Lasix]). Concurrent use with other ototoxic drugs is not recommended. ■ Has antihypertensive actions. May have an additive effect when used concurrently with **other antihypertensive agents** (e.g., hydralazine, nitroglycerin, nitroprusside sodium); reduced doses of both agents may be indicated. ■ Electrolyte depletion (especially hypokalemia) may increase with concurrent administration of **other drugs that cause potassium loss,** such as amphotericin B or corticosteroids (e.g., dexamethasone, hydrocortisone sodium succinate). ■ May increase or prolong the effects of **nondepolarizing muscle relaxants** (e.g., atracurium, pancuronium). ■ May interfere with the hypoglycemic effects of **insulin and antidiabetic agents** in patients with diabetes. Monitor glucose and serum potassium. Correct potassium levels first, then adjust insulin or antidiabetic agent dose as indicated. ■ Hypokalemia and hypomagnesemia may cause **digoxin**-induced arrhythmias; monitor potassium levels. ■ Synergistic effects with **other diuretics** may cause profound diuresis and serious electrolyte abnormalities. ■ May potentiate the effects of **warfarin** (Coumadin). Monitor INR; reduced warfarin dose may be indicated. ■ Concurrent use with **lithium** not recommended; renal excretion of lithium is decreased and potential for lithium toxicity is increased. ■ **NSAIDs** (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]) may decrease the effects of diuretics; monitor carefully. ■ **Probenecid** may reduce urinary excretion and the effectiveness of ethacrynic acid. ■ Concurrent use with **corticosteroids** may increase the risk of gastric hemorrhage.

SIDE EFFECTS

Most frequent with larger doses, in seriously ill patients, or with prolonged oral therapy. Abdominal discomfort or pain, agranulocytosis, anorexia, apprehension, chills, confusion, deafness (usually transient), diarrhea, dysphagia, fatigue, fever, GI bleeding, headache, hematuria, hyperglycemia, hyperuricemia, hypochloremic alkalosis, hypoglycemia, hypokalemia, hypomagnesemia, injection site pain and thrombophlebitis, jaundice and abnormal liver function, malaise, muscle cramps, nausea and vomiting, neutropenia, pancreatitis, skin rash, sudden onset of acute watery diarrhea, thirst, weakness.

Overdose:

Most common S/S are those caused by electrolyte depletion (e.g., hypochloremic alkalosis, hypokalemia, hyponatremia) and dehydration resulting from excessive diuresis. Cardiac arrhythmias may occur if digoxin is used concurrently. Circulatory collapse, deafness (permanent), embolism, hepatic coma, vascular thrombosis, and death have occurred.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Reduce ethacrynic acid dose or discontinue if side effects are moderate or severe. Treatment of moderate to severe side effects is symptomatic and aggressive. If acute watery diarrhea or S/S of hepatic coma occur, discontinue therapy. Treatment of overdose is symptomatic and supportive. Correct dehydration, electrolyte imbalance, hepatic coma, and hypotension. Maintain an adequate airway and use oxygen or artificial ventilation for respiratory distress as indicated. Resuscitate as necessary.

ETOMIDATE

(eh-**TOM**-ih-dayt)
Amidate
Anesthetic, general
Anesthesia adjunct
pH 4 to 7

USUAL DOSE

Rapid sequence intubation and/or induction of anesthesia:

Dose must be individualized. 0.3 mg/kg IV (range: 0.2 to 0.6 mg/kg). Titrate to effect. Smaller, incremental doses may be administered to adult patients during short operative procedures to supplement subpotent anesthetic agents, such as nitrous oxide.

Procedural sedation:

0.1 to 0.2 mg/kg has been used effectively. Subsequent doses of 0.05 mg/kg every 3 to 5 minutes may be administered as needed. If analgesia is required, concurrent administration of fentanyl may be used.

PEDIATRIC DOSE

Rapid sequence intubation and/or induction of anesthesia:

Pediatric patients up to 10 years of age:

Safety and effectiveness have not been established.

Pediatric patients 10 years of age and older:

See Usual Dose.

Procedural sedation (unlabeled):

0.1 to 0.3 mg/kg. Repeat doses may be needed based on the length of the procedure. If analgesia is required, concurrent administration of fentanyl may be used.

DOSE ADJUSTMENTS

Dose must be individualized for each patient. ■ Caution and lower-end dosing suggested in the elderly; consider decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. Solution must be clear.

Filters:

No data available from manufacturer.

Storage:

Store at CRT. Discard unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose equally distributed over 30 to 60 seconds. More-rapid injections may produce hypotension.

ACTIONS

A short-acting, nonbarbiturate general anesthetic without analgesic activity. Does not cause significant cardiovascular or respiratory depression. Has little or no effect on myocardial metabolism, cardiac output, peripheral circulation, or pulmonary circulation. Produces a slight increase in $Paco_2$. Does not elevate plasma histamine or cause signs of histamine release. Decreases cerebral blood flow and lowers intracranial pressure. Usually lowers intraocular pressure moderately. Onset of action is within 1 minute. Duration of action is dose dependent, usually 3 to 5 minutes at a dose of 0.3 mg/kg. Metabolized in the liver and excreted primarily in the urine. Half-life is approximately 75 minutes.

INDICATIONS AND USES

Induction of general anesthesia. Usefulness of hemodynamic properties should be weighed against the high frequency of transient skeletal muscle movements. ■ Supplementation of subpotent anesthetic agents (e.g., nitrous oxide in oxygen) during maintenance of anesthesia for short operative procedures such as dilation and curettage or cervical conization.

Unlabeled uses:

Procedural sedation, rapid sequence intubation (RSI).

CONTRAINDICATIONS

Hypersensitivity to etomidate. ■ Not recommended for use during labor and delivery.

PRECAUTIONS

For IV use only. ■ Should be administered by or under the direct supervision of persons trained in the administration of general anesthetics and in the management of complications encountered during general anesthesia (e.g., anesthesiologists, emergency department physicians) in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Induction doses of etomidate have been associated with the reduction of plasma cortisol and aldosterone concentrations that may last for 6 to 8 hours. Because of the hazards of prolonged suppression, etomidate is not intended for administration by prolonged infusion. Exogenous replacement (e.g., methylprednisolone) should be considered if concern exists for patients undergoing severe stress or for patients receiving chronic oral corticosteroid therapy (e.g., prednisone).

Monitor:

Monitor airway and vital signs. ■ Monitor injection site. Use of larger, more proximal arm veins is recommended to lessen incidence and severity of pain on injection. Avoid use of wrist or hand veins if possible. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following administration. ■ Do not perform tasks requiring mental alertness (e.g., driving, operating hazardous machinery) for 24 hours following administration. ■ Discuss with parents or caregivers the risks, benefits, timing, and duration of surgery or procedures requiring anesthetic and sedation drugs; see Maternal/Child.

Maternal/Child:

Safety for use in pregnancy not established; benefit must justify potential risks to fetus; see Contraindications. ■ Safety for use during breast-feeding not established; effects unknown. Use caution. ■ Safety and effectiveness for use in pediatric patients under 10 years of age not established. ■ Published studies suggest that repeated or prolonged exposures to anesthetic agents in utero (third trimester) and early in life (up to 3 years of age) may have negative effects on the developing brain, resulting in adverse cognitive or behavioral effects; see prescribing information for further discussion. Balance the benefits of appropriate anesthesia in pregnant women, neonates, and young children who require procedures with the potential risks described.

Elderly:

See Dose Adjustments. ■ May be more sensitive to effects. Administration in elderly patients, particularly in those with hypertension, may induce cardiac depression as evidenced by a decrease in heart rate, cardiac index, and mean arterial BP.

DRUG/LAB INTERACTIONS

Administration of **fentanyl** 0.1 mg before induction with etomidate may shorten the immediate recovery period and decrease the incidence of disturbing skeletal muscle movements. ■ May have additive effects with concomitant **anesthetics, sedatives, hypnotics, and/or opiates** (e.g., fentanyl); reduced doses of etomidate may be indicated. ■ Does not significantly alter the usual dosage requirements of **neuromuscular blocking agents** (e.g., vecuronium, rocuronium).

SIDE EFFECTS

The most common adverse reactions are transient venous pain on injection and transient skeletal muscle movements, including myoclonus, averting movements, and eye movements. Less frequently reported side effects include apnea of short duration (5 to 90 seconds with spontaneous recovery), arrhythmia, bradycardia, hiccups and/or snoring (may indicate partial airway obstruction), hypertension, hyperventilation, hypotension, hypoventilation, laryngospasm, postoperative nausea and vomiting, and tachycardia.

ANTIDOTE

Discontinue drug if significant side effects or overdose occur. Support patient. Establish and maintain an airway; administer oxygen with assisted ventilation if needed. Resuscitate as necessary.

ETOPOSIDE BBW

(eh-**TOH**-poh-syd)
Etopophos PF, Etoposide Phosphate, VP-16-213
Antineoplastic (topoisomerase inhibitor)
pH 2.9 to 4

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Testicular cancer:

50 to 100 mg/M^2 daily for 5 days or 100 mg/M^2/day on Days 1, 3, and 5. Repeat at 3- to 4-week intervals. Used in combination with other chemotherapy agents.

Small-cell lung cancer:

35 mg/M^2/day for 4 days to 50 mg/M^2/day for 5 days. Repeat at 3- to 4-week intervals. Used in combination with other chemotherapy agents.

DOSE ADJUSTMENTS

Modify dose if indicated based on myelosuppressive effects of other drugs administered in combination and any previous radiation therapy or chemotherapy (compromised bone marrow reserve). Frequently given in combination with cisplatin, bleomycin, and doxorubicin. ■ Withhold dose if platelets less than 50,000/mm^3 or absolute neutrophil count less than 500/mm^3. Do not restart until adequate recovery. ■ Dose selection should be cautious in the elderly. ■ Reduce dose by 25% if CrCl is 15 to 50 mL/min. Further reduction may be indicated if the CrCl is less than 15 mL/min. One source recommends decreasing dose by 50% if CrCl is less than 10 mL/min. ■ Dose reduction may be required in impaired hepatic function. One source recommends a dose reduction of 50% with a bilirubin of 1.5 to 3 or an AST greater than 3 times the ULN. Use in severe hepatic impairment is contraindicated in the Canadian product labeling.

DILUTION

Specific techniques required; see Precautions.

Nonphosphate Products (e.g., VePesid):

Each 100 mg (5 mL) must be diluted in at least 250 mL of D5W or NS and given as an infusion (0.4 mg/mL). 500 mL of solution will yield 0.2 mg/mL. Maximum concentration to prevent precipitation is 0.4 mg/mL. Monitor closely for precipitation from dilution to completion of infusion. Undiluted etoposide has caused acrylic or ABS plastic devices to crack and leak; handle carefully during dilution process.

Phosphate Product (e.g., Etopophos):

Reconstitute each 100-mg vial with 5 or 10 mL of SWFI, D5W, or NS (with or without benzyl alcohol). 5 mL of diluent will yield 20 mg/mL, 10 mL will yield 10 mg/mL. Further dilute to concentrations as low as 0.1 mg/mL with D5W or NS for administration. A 1-mg/mL solution has a pH of 2.9.

Storage:

Nonphosphate Products (e.g., VePesid): May be stored at CRT before dilution. Stable after dilution at CRT for 96 hours (0.2 mg/mL solution) or 24 hours (0.4 mg/mL) in D5W or NS. ***Phosphate Products (e.g., Etopophos):*** Refrigerate in carton until use to protect from light. Store reconstituted solutions under refrigeration at 2° to 8° C (36° to 46° F) for 7 days. Solutions reconstituted with nonbacteriostatic diluents may be stored at CRT for up to 24 hours. Solutions reconstituted with bacteriostatic diluents may be stored at CRT for up to 48 hours. Store fully diluted solutions under refrigeration or at CRT for up to 24 hours.

COMPATIBILITY

Nonphosphate Products (e.g., VePesid)

Hydrolysis may occur in alkaline solutions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Phosphate Products (e.g., Etopophos)

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Nonphosphate Products (e.g., VePesid):

Total desired dose, properly diluted (0.2 to 0.4 mg/mL) and evenly distributed over at least 30 to 60 minutes. Rapid infusion may cause marked hypotension. May be extended if fluid volume is a concern.

Phosphate Products (e.g., Etopophos):

Total desired dose, properly reconstituted and diluted, may be given evenly distributed over as little as 5 minutes or up to 3.5 hours. Do not give as a bolus injection.

ACTIONS

A semi-synthetic derivative of podophyllotoxin. A topoisomerase II inhibitor that is cell cycle–specific for the G_2 phase. Appears to cause DNA strand breaks. Etopophos (phosphate) is a phosphate ester of etoposide that promptly converts to etoposide in plasma. The pharmacokinetics and pharmacodynamics of etoposide are similar after administration of either the phosphate or non-phosphate products. Half-life is from 4 to 11 hours (average is 7 hours). Bound to human plasma proteins, primarily albumin. Metabolized in the liver. Primarily excreted as unchanged drug or metabolites through urine and bile (feces).

INDICATIONS AND USES

Treatment of refractory testicular tumors (used in combination with other chemotherapeutic drugs). ■ Treatment of small-cell lung cancer (used in combination with cisplatin as first-line treatment).

Unlabeled uses:

Conditioning regimen for hematopoietic cell transplantation. Treatment of acute lymphocytic leukemias (ALL), Hodgkin lymphoma, non-Hodgkin lymphomas, carcinoma of the breast, neuroblastoma, Wilms' tumor, and many malignancies. Used alone or in combination with other agents.

CONTRAINDICATIONS

Hypersensitivity to etoposide, etoposide phosphate, or any other component of the formulations.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. Always wear impervious gloves when handling vials containing etoposide. If a solution of etoposide contacts the skin, wash the skin immediately and thoroughly with soap and water. If there is contact with mucous membranes, flush thoroughly with water. ■ For IV infusion only; do not give as a bolus injection. ■ Usually administered by or under the direction of the physician specialist. ■ Severe myelosuppression with resulting infection or bleeding may occur. Deaths have been reported. ■ A low serum albumin may result in an increase of free (active) etoposide, resulting in an increased risk of toxicity. Occurs more frequently in pediatric patients. ■ Hypersensitivity reactions have been reported. Higher-than-recommended concentration, the presence of polysorbate 80, and a rapid rate of infusion may contribute to the development of these reactions. ■ Secondary leukemias have occurred with long-term use. ■ Use with caution in hepatic or renal impairment; see Dose Adjustments. ■ Oral dose of nonphosphate product (e.g., etoposide) is usually twice the IV dose.

Monitor:

Determine absolute patency and quality of vein and adequate circulation of extremity. Avoid extravasation; may result in cellulitis, pain, swelling, and necrosis, including skin necrosis. ■ Obtain baseline CBC with differential and platelets. Monitor before each dose and between courses. See Dose Adjustments. ■ Monitor vital signs during infusion. ■ Examine patient's mouth for ulceration before each dose. ■ Monitor hepatic and renal function before and during therapy. ■ Bone marrow recovery from a course is usually complete within 21 days. No cumulative toxicity has been reported as yet. ■ Be alert for signs of bone marrow suppression or infection. ■ Monitor for S/S of hypersensitivity reactions (e.g., bronchospasm, chills, dyspnea, fever, hypotension, pruritus, rash, tachycardia, urticaria). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may increase patient comfort.

Patient Education:

Female patients should use effective contraception during treatment and for at least 6 months after the final dose. Males with female sexual partners of reproductive potential should use condoms during treatment and for 4 months after the final dose. ■ Notify provider of known or suspected pregnancy. ■ Periodic monitoring of blood counts is required. ■ Promptly report new onset of bleeding, fever, or S/S of infection. ■ Report IV site burning or stinging promptly. ■ Report chills, difficult breathing, fever, and rapid heartbeat promptly. See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Can cause fetal harm. ■ May cause infertility. In male patients, may result in oligospermia, azoospermia, and permanent loss of fertility. May damage spermatozoa and testicular tissue, resulting in possible genetic fetal abnormalities. In female patients, may cause infertility and result in amenorrhea and premature menopause; see Patient Education. ■ Discontinue breast-feeding. ■ Has been used in pediatric patients, but safety and effectiveness not established. Higher rates of anaphylactic-like reactions have occurred in pediatric patients who have received infusions of etoposide at higher-than-recommended concentrations. See Precautions. ■ Depending on the preparation, VePesid may contain benzyl alcohol or polysorbate 80.

Elderly:

Numbers in clinical studies insufficient to determine if elderly patients respond differently than do younger subjects. ■ Monitor renal, hepatic, and hematologic function closely. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

All products:

Concurrent or consecutive use with other **bone marrow suppressants** (e.g., bleomycin, cisplatin, doxorubicin) **and/or radiation therapy** may produce additive bone marrow suppression. See Dose Adjustments. ■ Antineoplastic activity of etoposide and **cisplatin** may be synergistic against some tumors. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Clearance decreased and toxicity increased by **cyclosporine.** ■ May potentiate **warfarin;** monitor PT/INR. ■ Concomitant use of **antiepileptic medications**, including phenytoin, phenobarbital, carbamazepine, and valproic acid, may increase clearance and reduce efficacy of etoposide. ■ Phenylbutazone, sodium salicylate, and aspirin-displaced protein-bound etoposide in vitro. ■ May be a substrate of the P-glycoprotein (P-gp) transporter system based on in vitro studies.

Phosphate Product (e.g., Etopophos):

Use caution with drugs that are **known to inhibit phosphatase activities** (e.g., levamisole [Ergamisol]).

SIDE EFFECTS

Bone marrow toxicity (e.g., leukopenia, neutropenia, thrombocytopenia) can be severe, is dose related, and may be dose limiting. Side effects are usually reversible: abdominal pain, aftertaste, alopecia, anaphylactic-like reactions (bronchospasm, chills, diaphoresis, dyspnea, facial flushing, fever, hypertension or hypotension, pruritus, rash, tachycardia), anemia, anorexia, asthenia, back pain, constipation, coughing, cyanosis, diarrhea, dizziness, dysphagia, elevated liver function tests (e.g., AST, ALT), facial/tongue swelling, hepatic toxicity, hypertension, hypotension, interstitial pneumonitis/pulmonary fibrosis, laryngospasm, local soft tissue toxicity following extravasation, malaise, mucositis, nausea, neuritic pain, optic neuritis, paralytic ileus, peripheral neurotoxicity, pigmentation, radiation recall dermatitis, seizures, Stevens-Johnson syndrome, stomatitis, taste alteration, thrombophlebitis, toxic epidermal necrolysis, transient cortical blindness, urticaria, vomiting. Hepatic toxicity and metabolic acidosis have occurred with higher-than-recommended doses.

Post-Marketing:

Acute renal failure and extravasation.

Overdose:

No antidote has been established for overdose. In animal studies, overdosage may result in neurotoxicity.

ANTIDOTE

Notify the physician of all side effects; symptomatic treatment is often indicated, and dose reduction or discontinuation may be necessary. For extravasation, discontinue the drug immediately and administer into another vein. No specific treatment for extravasation is recommended. Hypotension is usually due to a rapid infusion rate. Discontinue infusion. Trendelenburg position and IV fluids should reverse the hypotension; vasopressors (e.g., dopamine) may be required. After recovery, restart at slower rate. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Discontinue infusion at the first sign of a hypersensitivity reaction; antihistamines, corticosteroids, pressor agents, or volume expanders may be indicated. Permanently discontinue in patients who experience a severe hypersensitivity reaction. Resuscitate as necessary.

USUAL DOSE (International units [IU])

All Formulations

Completely individualized based on patient's circumstances, condition, degree of deficiency, and desired blood level percentage. Specific products may be indicated or preferred in some situations; see Indications and Uses. Range is 10 to 75 International units (IU)/kg of body weight. May be repeated every 12 hours in some situations, required only every 2 or 3 days in others. Actual number of International units contained shown on each bottle or vial. Units required to raise blood level percentages can be calculated as follows:

Body weight (kg) × Desired increase (% of normal) × 1 Unit/kg

(70 kg × 40% increase × 1 IU/kg = 2,800 IU). To maintain levels above 25%, calculate each dose to raise level to 40% to 60% of normal.

Minor hemorrhage:

A single injection calculated to increase plasma level to 20% to 30%. May be repeated in 24 hours if indicated.

Major trauma or surgery:

Increase plasma level to 25% to 50% and maintain at that level for a minimum of 1 week or as indicated. May require daily injections (every 18 to 30 hours).

Dental extraction:

Increase plasma level to 50% before procedure; repeat if indicated.

Prophylaxis:

10 to 20 IU/kg once or twice a week or increase plasma level to 20% to 30%.

Factor IX Complex

Reversal of coumarin effect:

15 IU/kg.

DILUTION

Diluent usually provided. Some preparations also supply double-ended needles for dilution and filter needle for aspiration into a syringe. Sterile technique imperative. Confirm expiration date. Use plastic syringes to prevent binding to glass surfaces. Factor IX and diluent should be at room temperature. Direct diluent from above to side of vial to gently moisten all contents. Swirl gently to dissolve; avoid foaming. Do not shake. May take 1 to 5 minutes. Should be clear and colorless. Must be used within 3 hours to avoid bacterial contamination. The addition of 2 to 3 units of heparin/mL factor IX complex may reduce the incidence of thrombosis. May be given through an IV administration set (often provided) if multiple vials are required. Discard any unused contents. Discard all administration equipment after single use; do not attempt to resterilize.

AlphaNine SD:

Follow general directions above. After diluent is drawn through double-ended needle, remove diluent bottle first; then remove double-ended needle. ***Do not invert concentrate vial until ready to withdraw contents!*** Air from syringe into vial required to withdraw contents. Withdraw through filter.

Mononine:

Follow general directions listed previously. After diluent is drawn through double-ended needle, remove diluent bottle first; then remove double-ended needle. ***Use only the provided self-venting filter spike to transfer Mononine to a syringe! Do not inject any air into Mononine vial; could cause product loss.*** Discard filter and use only provided wing needle and micropore tubing to administer.

Filters:

Usually supplied by manufacturer. If more than one vial is required for a dose, multiple vials may be drawn into the same syringe; however, a new filter needle must be used to withdraw the contents of each vial of factor IX and/or factor IX complex (Human). Manufacturers of ***AlphaNine SD*** and ***Mononine*** provide a filter needle, which is to be used to withdraw reconstituted solution into a syringe. Discard filter needle after aspiration into the syringe. No further filtering is required for administration.

Storage:

Store lyophilized powder at 2° to 8° C (36° to 46° F); do not freeze. Do not refrigerate after dilution. ***Mononine*** may be stored at room temperature before dilution for up to 30 days.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Average rate is 2 to 3 mL or 100 units/min. Completely individualized according to patient's condition. Decrease rate of administration for side effects such as burning or pain at injection site, chills, fever, flushing, headache, tingling, or changes in BP or pulse. Never exceed 10 mL/min.

ACTIONS

A lyophilized concentrate of human coagulation factors: IX (plasma thromboplastin and antihemophilic factor B), II (prothrombin), VII (proconvertin), and X (Stuart-Prower factor). In contrast to other products, AlphaNine SD and Mononine are highly purified factor IX and contain only minimal amounts of the other factors. All products are obtained from fresh human plasma and prepared, irradiated, and dried by specific processes. Additional processes are used to prepare AlphaNine SD and Mononine that markedly reduce the possibility of viral contamination. Concentration of 25 units/mL is 25 times greater than normal plasma. Preparations contain varying amounts of total protein in each vial. Half-life is approximately 24 hours (range 18 to 36 hours).

INDICATIONS AND USES

All factor IX products:

Prevention/control of bleeding in patients with factor IX deficiency due to hemophilia B. Indicated to correct or prevent a dangerous bleeding episode or to perform surgery. ■ Prophylaxis to prevent spontaneous bleeding in patients with proven specific congenital deficiency (hemophilia B).

Factor IX (human):

Preferred for surgical coverage; treatment of crush injuries and/or large IM hemorrhages requiring several days of replacement therapy; and treatment in neonates, individuals with severe hepatocellular dysfunction, or those with a history of thrombotic complications associated with factor IX complex.

Factor IX complex:

Prevention/control of bleeding in patients with hemophilia A who have inhibitors to factor VIII. ■ Reversal of coumarin effect (fresh frozen plasma preferred unless risk of hepatitis transfer would be life threatening). ■ Hemorrhage caused by hepatitis-induced lack of production of liver-dependent coagulation factors. ■ Proplex T is used for prevention or control of bleeding episodes in patients with factor VII deficiency.

CONTRAINDICATIONS

Factor IX complex:

Known liver disease with suspicion of intravascular coagulation or fibrinolysis. ■ Factor VII deficiency except for Proplex T.

Mononine:

Known hypersensitivity to mouse protein. ■ No other known contraindications for **AlphaNine SD** or **Bebulin VH.** ■ **AlphaNine SD, Bebulin VH,** and **Mononine** are not indicated for replacement of any other coagulation factors.

PRECAUTIONS

Used when plasma infusions would result in hypervolemia and/or proteinemia or when blood volume or RBC replacement is not indicated. ■ Use extreme caution in newborns, infants, postoperative patients, and patients with liver disease. Factor IX (human) (e.g., AlphaNine SD, Mononine) would be preferred because studies show no incidence of thrombin generation. ■ Fresh frozen plasma may be required in addition to factor IX complex when prompt reversal is required. ■ Danger of thromboembolic episodes (DIC, myocardial infarction, pulmonary embolism, venous thrombosis) increases with plasma levels over 50%. ■ Large or frequently repeated doses of factor IX complex may cause intravascular hemolysis in patients with type A, B, or AB blood.

Monitor:

Monitor the patient's levels of coagulation factors before, after, and between administrations. ***Do not overdose;*** see Side Effects. ■ AIDS or hepatitis is possible for the recipient. Health care professionals should exercise caution in handling. Possibility markedly reduced with additional preparation process of AlphaNine SD and Mononine. ■ Observe for signs and symptoms of postoperative thrombosis or disseminated intravascular coagulation (DIC). Risk multiplies with repeated administrations except for AlphaNine, AlphaNine SD, and Mononine.

Patient Education:

Alert to possible risk of HIV virus and hepatitis. ■ Report early signs of hypersensitivity promptly (burning or pain along injection site, hives, rash, tightness of chest, wheezing). ■ Notify physician if medication seems less effective. May be developing antibodies to factor IX. ■ Carry identification card. ■ Proper preparation and administration imperative if given in home.

Maternal/Child:

Category C: safety for use during pregnancy not established; use only if clearly indicated; see Precautions. ■ Use extreme caution in neonates with hepatitis; high rate of morbidity.

DRUG/LAB INTERACTIONS

Concurrent use of **aminocaproic acid** may increase risk of thrombosis.

SIDE EFFECTS

Burning or pain along injection site, changes in BP, chills, fever, flushing, headache, nausea, tingling, urticaria, vomiting.

Major:

Anaphylaxis, DIC, hepatitis, myocardial infarction, postoperative thrombosis (rare with pure factor IX [Human] products), pulmonary embolism. Consider risk potential of contracting AIDS and hepatitis; markedly reduced with pure factor IX (Human) products (AlphaNine, AlphaNine SD, and Mononine).

ANTIDOTE

Temporarily discontinue or decrease rate of administration for minor side effects. For major symptoms, discontinue, and notify physician. Treat hypersensitivity reactions as indicated; a different lot may not cause reaction. For thrombosis or DIC, anticoagulation with heparin may be indicated.

FACTOR IX (RECOMBINANT)

(**FAK**-tor **NINE** [re-**KOM**-be-nant])
Alprolix, BeneFIX, IDELVION, IXINITY, RIXUBIS
Antihemorrhagic

USUAL DOSE (International units [IU])

Available recombinant factor IX products include:

Alprolix (recombinant):

A coagulation factor IX Fc fusion protein consisting of the human coagulation factor IX sequence covalently linked to the Fc domain of human immunoglobulin G_1 (IgG_1). Does not contain proteins derived from animal or human sources.

BeneFIX (recombinant), IXINITY (recombinant), RIXUBIS (recombinant):

Coagulation factor IX proteins produced by a genetically engineered mammalian cell line derived from Chinese hamster ovary (CHO) cells. No human or animal proteins are added during any stage of manufacturing.

IDELVION (recombinant):

A coagulation factor IX, albumin fusion protein (rIX-FP) comprising genetically fused recombinant coagulation factor IX and recombinant albumin. Does not contain proteins derived from animal or human sources.

Adults and pediatric patients:

Completely individualized based on the degree of deficiency, the location and extent of bleeding, the patient's clinical condition and age, and the pharmacokinetic parameters of factor IX, such as incremental recovery and half-life. Base dose and frequency on individual clinical response. Units required to raise blood level percentages are somewhat increased with recombinant products compared with other factor IX products and can be calculated using the following formulas:

Number of factor IX IU required = Body weight (in kg) × Desired factor IX increase (% of normal or IU/dL) × Reciprocal of observed recovery (IU/kg per IU/dL)

The observed recovery for the various products is as follows:

Alprolix:

One IU of recombinant product/kg of body weight increases the circulating level of factor IX by 1% (IU/dL).

BeneFIX:

One IU of recombinant product/kg of body weight increases the circulating level of factor IX by 0.8% (IU/dL) for adults and by 0.7% (IU/dL) in pediatric patients under 15 years of age.

IDELVION:

One IU of recombinant product/kg of body weight is expected to increase the circulating level of factor IX by 1.3% (IU/dL) in patients 12 years of age or older and by 1% (IU/dL) in pediatric patients under 12 years of age.

IXINITY:

One IU of recombinant product/kg of body weight increases the circulating level of factor IX by 0.98% (IU/dL).

RIXUBIS:

One IU of recombinant product/kg of body weight increases the circulating level of factor IX by 0.9% (IU/dL) for patients 12 years of age or older and by 0.7% (IU/dL) in pediatric patients under 12 years of age.

In the presence of an inhibitor, higher doses may be required. See examples of dose calculation in prescribing information.

The following chart may be used to guide dosing in the prevention of bleeding episodes.

Factor IX (Recombinant) Dosing Guidelines for Prevention and Control of Bleeding in Adults and Pediatric Patients			
Type of Bleeding Episodes	**Circulating Factor IX Activity Required (% of normal or IU/dL)**	**Dosing Interval (hours)**	**Duration of Therapy (days)**
Minor Uncomplicated or early bleeds: hemarthroses, superficial muscle (except iliopsoas) with no neurovascular compromise, other soft tissue or oral bleeding	**Alprolix** 30 to 60	48 hours	Repeat every 48 hours if there is further evidence of bleeding
	BeneFIX 20 to 30	12 to 24 hours	1 to 2 days
	IDELVION[a] 30 to 60	48 to 72 hours	At least 1 day until bleeding stops and healing is achieved A single dose should be sufficient for the majority of bleeds
	IXINITY 30 to 60	24 hours	1 to 3 days until healing is achieved
	RIXUBIS 20 to 30	12 to 24 hours	At least 1 day until healing is achieved

Moderate Intramuscular or soft tissue with dissection, mucous membranes, dental extractions, hematuria, hemarthrosis of longer duration, recurrent hemarthrosis, deep lacerations	**Alprolix** 30 to 60	48 hours	Repeat every 48 hours if there is further evidence of bleeding
	BeneFIX and RIXUBIS 25 to 50	12 to 24 hours	Treat until bleeding stops and healing begins, about 2 to 7 days
	IDELVION[a] 30 to 60	48 to 72 hours	At least 1 day until bleeding stops and healing is achieved A single dose should be sufficient for the majority of bleeds
	IXINITY 40 to 60	24 hours	2 to 7 days until healing is achieved
Major Life-threatening or limb-threatening hemorrhage, iliopsoas and deep muscle with neurovascular injury or substantial blood loss, pharyngeal, retropharyngeal, retroperitoneal, CNS	**Alprolix** 80 to 100	Consider a repeat dose after 6 to 10 hours and then every 24 hours for the first 3 days	Due to the long half-life of Alprolix, the dose may be reduced and frequency may be extended after Day 3 to every 48 hours or longer until bleeding stops and healing is achieved
	BeneFIX and RIXUBIS 50 to 100	12 to 24 hours	7 to 10 days until bleeding stops and healing is achieved
	IDELVION[a] 60 to 100	48 to 72 hours	7 to 14 days until bleeding stops and healing is achieved Maintenance dose weekly
	IXINITY 60 to 100	12 to 24 hours	2 to 14 days until healing is achieved

IU, International units.

[a]Adapted from the WFH Guidelines for the Management of Hemophilia.

Source: Roberts and Eberst and Srivastava et al. 2013.

Dosing for perioperative management is provided in the following chart.

Factor IX (Recombinant) Dosing for Perioperative Management in Adults and Pediatric Patients			
Type of Surgery	**Circulating Factor IX Level Required (% or IU/dL)**	**Dosing Interval (hours)**	**Duration of Therapy (days)**
Minor (e.g., tooth extraction)	**Alprolix** 50 to 80	A single infusion may be sufficient	Repeat as needed after 24 to 48 hours until bleeding stops and healing is achieved
	BeneFIX 20 to 30	12 to 24 hours	1 to 2 days until bleeding stops and healing is achieved
	IDELVION[a] 50 to 80	48 to 72 hours	At least 1 day or until healing is achieved A single dose should be sufficient for the majority of minor surgeries
	IXINITY **Preoperative:** 50 to 80 **Postoperative:** 30 to 80	24 hours	1 to 5 days depending on type of procedure
	RIXUBIS 30 to 60	24 hours	At least 1 day until healing is achieved
Major (e.g., intracranial, intra-abdominal, intrathoracic, joint replacement, pharyngeal, retropharyngeal, retroperitoneal)	**Alprolix** 60 to 100 (initial level)	Consider a repeat dose after 6 to 10 hours and then every 24 hours for the first 3 days	Due to the long half-life of Alprolix, the dose may be reduced and frequency in the postsurgical setting may be extended after Day 3 to every 48 hours or longer until bleeding stops and healing is achieved
	BeneFIX 50 to 100	12 to 24 hours	7 to 10 days until bleeding stops and healing is achieved
	IDELVION[a] 60 to 100 (initial level)	48 to 72 hours	7 to 14 days or until bleeding stops and healing is achieved Repeat dose every 48 to 72 hours for the first week or until healing is achieved Maintenance dose 1 to 2 times per week
	IXINITY **Preoperative:** 60 to 80 **Postoperative:** 40 to 60 **Postoperative:** 30 to 50 **Postoperative:** 20 to 40	8 to 24 hours	1 to 3 days 4 to 6 days 7 to 14 days
	RIXUBIS 80 to 100	8 to 24 hours	7 to 10 days until bleeding stops and healing is achieved

[a] Adapted from the WFH Guidelines for the Management of Hemophilia.

Routine prophylaxis dosing is as follows:

Alprolix dosing for routine prophylaxis in adults and pediatric patients:

Routine starting regimens are either 50 IU/kg once weekly or 100 IU/kg once every 10 days. Adjust dose based on patient response.

IDELVION dosing for routine prophylaxis in patients 12 years of age or older:

Recommended dose is 25 to 40 IU/kg every 7 days. Patients who are well-controlled on this regimen may be switched to a 14-day interval at 50 to 75 IU/kg.

IDELVION dosing for routine prophylaxis in pediatric patients under 12 years of age:

Recommended dose is 40 to 55 IU/kg every 7 days.

RIXUBIS dosing for routine prophylaxis in adults:

Dose for previously treated patients is 40 to 60 IU/kg twice weekly for patients 12 years of age and older and 60 to 80 IU/kg twice weekly for patients under 12 years of age. Dose titration may be necessary based on individual patient's age, bleeding pattern, and physical activity.

DOSE ADJUSTMENTS

Adjust dose and frequency of repeated infusions by using factor IX activity and pharmacokinetic parameters such as half-life and incremental recovery, as well as by taking the clinical situation into consideration. ■ Patients at the lower end of the observed factor IX recovery range may require upward dose adjustment; see Monitor. ■ Dose adjustment may be necessary in pediatric patients under 12 years of age; see Maternal/Child.

DILUTION (International units [IU])

Actual number of International units (IU) contained is shown on each bottle or vial. **Alprolix** is supplied in a kit that includes single-use vials containing 500, 1,000, 2,000, or 3,000 IU/vial. **BeneFIX** is supplied in a kit that includes single-use vials containing 250, 500, 1,000, 2,000, or 3,000 IU/vial. **IDELVION** is available in a kit that includes single-use vials containing 250, 500, 1,000, or 2,000 IU/vial. **IXINITY** is available in single-use vials containing 500, 1,000, or 1,500 IU/vial. **RIXUBIS** is available in single-use vials containing 250, 500, 1,000, 2,000, or 3,000 IU/vial. Sterile technique imperative. Confirm expiration date. Plastic syringes may be indicated to prevent binding to glass surfaces. Factor IX and diluent should be at room temperature. Provided diluent, dilution, and transfer equipment are specific to each product; consult manufacturer's detailed preparation and reconstitution process in prescribing information. When diluted, solution should be clear and colorless. (**IDELVION** may be yellow to colorless.) Multiple vials may be drawn in the same larger syringe per manufacturer's specific directions. Most products must be used within 3 hours of reconstitution. **IDELVION** must be used within 4 hours of reconstitution.

Filters:

Supplied by manufacturer if indicated. If more than one vial is required for a dose, multiple vials may be drawn into the same syringe; see Dilution.

Storage:

Alprolix: Refrigerate kit at 2° to 8° C (36° to 46° F). Store in original package and protect from light. ***Do not refrigerate after reconstitution.***

BeneFIX:

If product is labeled for RT storage, it may be stored at CRT or refrigerated at 2° to 8° C (36° to 46° F). If product is labeled for refrigeration, store at 2° to 8° C (36° to 46° F).

IDELVION:

Store in original carton to protect from light in the refrigerator or at RT (2° to 25° C [36° to 77° F]). Do not freeze. ***Do not refrigerate after reconstitution.***

IXINITY:

Store at 2° to 25° C (36° to 77° F) in original carton to protect from light. ***Do not refrigerate after reconstitution.***

RIXUBIS:

Refrigerate at 2° to 8° C (36° to 46° F) for up to 24 months.

All products:

Avoid freezing. Do not use after the expiration date. Discard unused product. ***All products except IDELVION:*** Must be used within 3 hours of reconstitution. ***IDELVION*** must be used within 4 hours of reconstitution. ***Alprolix, BeneFIX,*** and ***RIXUBIS*** may be stored at room temperature not exceeding 30° C (86° F) for up to 6 months (12 months for RIXUBIS) before expiration (mark date removed from refrigerator on carton). Do not return to the refrigerator.

COMPATIBILITY

Alprolix, IXINITY:

Manufacturer states, “Do not administer in the same tubing or container with other medications.”

BeneFIX:

Do not administer in the same tubing or container with other medicinal products. Do not allow blood to enter the syringe; if red blood cell agglutination is observed, discard everything and start over with new product and supplies.

IDELVION:

Manufacturer states, “Do not mix or administer in the same tubing or container with other medicinal products.”

RIXUBIS:

Specific information not available. Consider specific use; consult pharmacist and note **compatibility** under BeneFIX.

RATE OF ADMINISTRATION

Alprolix, IDELVION, IXINITY, RIXUBIS:

Administer as an IV bolus infusion. Rate of administration should be determined by patient's comfort level and no faster than 10 mL/min.

BeneFIX:

Administer over a period of several minutes. Adapt to the comfort level of each individual patient.

All products:

Record the name and batch number of the product in the patient record.

ACTIONS

An antihemorrhagic. A purified protein produced by recombinant DNA technology for use in the treatment of factor IX deficiency. Its primary amino acid sequence is identical to a form of plasma-derived factor IX, and it has structural and functional characteristics similar to those of endogenous factor IX. Inherently free from the risk of transmission of human bloodborne pathogens such as HIV, hepatitis viruses, and parvovirus. Factor IX is the specific clotting factor deficient in patients with hemophilia B and in patients with acquired factor IX deficiencies. Factor IX (recombinant) increases plasma levels of factor IX and can temporarily correct the coagulation defect in these patients, restoring hemostasis. Normalizes aPTT. Average half-life of ***Alprolix*** is 86 hours. Half-life of ***BeneFIX*** ranges from 11 to 36 hours. The fusion of the recombinant coagulation factor IX with recombinant albumin extends the half-life of factor IX with ***IDELVION***. The half-life of ***IDELVION*** ranges from 104 to 118 hours in adults and from 87 to 93 hours in pediatric patients under 18 years of age (depending on dose). ***IXINITY*** half-life ranges from 17 to 31 hours. ***RIXUBIS*** half-life ranges from 16 to 42 hours.

INDICATIONS AND USES

All Products:

Control and prevention of bleeding episodes in adult and pediatric patients with hemophilia B (congenital factor IX deficiency or Christmas disease). ■ Perioperative management in adult and pediatric patients with hemophilia B. **IXINITY** use is limited to patients 12 years of age or older.

Alprolix, IDELVION, RIXUBIS:

Routine prophylaxis to prevent or reduce the frequency of bleeding episodes in adults and pediatric patients with hemophilia B.

Limitations of use:

All Products:

Not indicated for induction of immune tolerance in patients with hemophilia B; see Precautions.

BeneFIX:

Not indicated for treatment of other factor deficiencies (e.g., factors II, VII, VIII, and X), hemophilia A patients with inhibitors to factor VIII, reversal of coumarin-induced anticoagulation, or bleeding due to low levels of liver-dependent coagulation factors.

CONTRAINDICATIONS

Alprolix:

Known history of hypersensitivity reactions (including anaphylaxis) to the product or its excipients.

BeneFIX, IDELVION, IXINITY, RIXUBIS:

Known history of hypersensitivity to the products or their excipients, including hamster protein.

RIXUBIS:

Disseminated intravascular coagulation (DIC) and/or signs of fibrinolysis.

PRECAUTIONS

All Products:

For IV bolus infusion only; see Rate of Administration. Safety and effectiveness of continuous infusion have not been established. ■ Usually administered under the supervision of a physician experienced in the treatment of hemophilia B. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Risk may be highest during the early phases of initial exposure in previously untreated patients. An association between the occurrence of factor IX inhibitor and allergic reactions has been reported. ■ Thromboembolic episodes (e.g., disseminated intravascular coagulation [DIC], myocardial infarction, pulmonary embolism, arterial or venous thrombosis) have been reported with factor IX concentrates. Most have been reported in patients receiving factor IX complex concentrates or factor IX via continuous infusions. ■ Because of potential thromboembolic problems, use caution in patients with liver disease, patients with signs of fibrinolysis, patients in the perioperative or postoperative period, neonates, or patients at risk for thromboembolic phenomena or DIC. Benefit must be weighed against risk. ■ Factor IX inhibitors may develop; see Monitor. ■ Nephrotic syndrome has been reported following attempted immune tolerance induction in hemophilia B patients with factor IX inhibitors. Safety for use in immune tolerance induction not established.

Monitor:

All Products:

To ensure desired factor IX activity levels are achieved and maintained, precise monitoring using the one-stage factor IX activity assay is recommended, especially during surgical intervention. Adjust dose and frequency as required. *Do not overdose;* see Side Effects. ■ Monitor vital signs. ■ Monitor for S/S of hypersensitivity reaction (e.g., angioedema, chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria, wheezing). ■ Monitor for early signs of thrombotic events and consumptive coagulopathy; see Precautions. ■ Monitor for development of factor IX inhibitors. Failure to attain the expected factor IX activity plasma levels or to control bleeding with an appropriate dose may indicate development of factor IX inhibitors. Assays used to determine if factor IX inhibitor is present should be titered in Bethesda units (BUs). ■ Patients dosed with high-purity factor IX products who develop inhibitors are at increased risk for anaphylaxis with repeat doses. Evaluate patients who experience a hypersensitivity reaction for the presence of an inhibitor.

Patient Education:

All Products:

Read manufacturer-supplied patient product information. ■ Hypersensitivity reactions can occur. Promptly report difficulty breathing, hives, itching, tightness of the chest, and/or wheezing. If self-administering, discontinue use and contact physician immediately. ■ Contact provider for lack of clinical response. May indicate development of inhibitors.

Maternal/Child:

All Products:

Use during pregnancy only if clearly indicated and/or the potential benefit justifies the potential risk. ■ Use caution during breast-feeding. ■ Pediatric patients may have higher factor IX body weight–adjusted clearance, shorter half-life, and lower recovery. Higher dose per kilogram of body weight or more frequent dosing may be needed. ■ Safety and effectiveness of IXINITY for use in pediatric patients under 12 years of age not established.

Elderly:

All Products:

Numbers in clinical studies insufficient to determine whether the elderly respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

Specific information not available. Factor IX activity measurements in the clinical lab may be affected by the type of activated partial thromboplastin time (aPTT) reagent or laboratory standard used.

SIDE EFFECTS

Alprolix:

Headache and oral paresthesia were most common. Breath odor, dizziness, dysgeusia, fatigue, hypotension, infusion site pain, obstructive uropathy, and palpitations have been reported. No inhibitors were detected and no events of anaphylaxis were reported during clinical studies.

BeneFIX:

Dizziness, headache, injection site pain, injection site reaction, nausea, and rash were most common. Blurred vision, cellulitis at IV site, chest tightness, drowsiness, dry cough, factor IX inhibition, fever, flushing, hives, hypoxia, phlebitis at IV site, renal infarct, shaking, taste perversion, and vomiting have been reported. Hypersensitivity reactions (including bronchospastic reactions and/or hypotension and anaphylaxis) and the development of high-titer inhibitors requiring alternate treatments to factor IX therapy are the most serious.

IDELVION:

Most commonly reported reaction is headache. Dizziness, eczema, hypersensitivity reactions, and rash have been reported.

IXINITY:

Most commonly reported reaction is headache. Apathy, asthenia, depression, dysgeusia, influenza, injection site discomfort, lethargy, and pruritic rash have been reported.

RIXUBIS:

Dysgeusia, pain in extremity, and positive furin antibody test were most common during clinical studies.

All Products:

Anaphylaxis, angioedema, dyspnea, hypotension, inadequate factor IX recovery, inhibitor development, and thrombosis may occur.

Post-Marketing:

BeneFIX:

Anaphylaxis, angioedema, dyspnea, hypotension, and thrombosis.

RIXUBIS:

Hypersensitivity (including dyspnea, pruritus), rash, and urticaria.

ANTIDOTE

Temporarily discontinue or decrease rate of administration for minor side effects. If any major symptoms appear, discontinue drug, notify physician, and consider alternative hemostatic measures. Treat hypersensitivity reactions as indicated. For thrombosis or DIC, anticoagulation with heparin may be indicated.

FACTOR XIII CONCENTRATE (HUMAN)

(**FAK**-tor **THIR**-teen **KON**-sen-trayt **HUE**-man)
Corifact
Antihemorrhagic

USUAL DOSE (International units [IU])

Dose must be individualized based on body weight, laboratory values, and patient's clinical condition.

Initial dose in adult and pediatric patients:

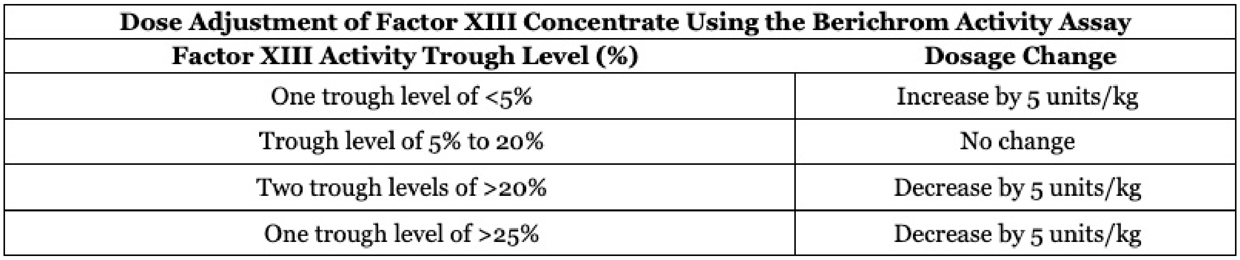
40 IU/kg.

Subsequent doses in adult and pediatric patients:

Should be guided by the most recent trough factor XIII (coagulation factor XIII) activity level. Dose every 28 days (4 weeks) to maintain a trough factor XIII activity level of approximately 5% to 20%. Recommended dosing adjustments of ±5 units/kg should be based on trough factor XIII activity levels as shown in the chart in Dose Adjustments and on the patient's clinical condition.

DOSE ADJUSTMENTS

Guide dose adjustments based on a specific assay used to determine factor XIII levels (e.g., Berichrom Activity Assay).



Dose Adjustment of Factor XIII Concentrate Using the Berichrom Activity Assay

Factor XIII Activity Trough Level (%)	Dosage Change
One trough level of <5%	Increase by 5 units/kg
Trough level of 5% to 20%	No change
Two trough levels of >20%	Decrease by 5 units/kg
One trough level of >25%	Decrease by 5 units/kg

DILUTION

Available as a single-use vial containing 1,000 to 1,600 units of factor XIII as a lyophilized concentrate. Actual units of potency stated on vial label. Sterile diluent and Mix2Vial filter transfer set provided. Sterile technique imperative. Confirm expiration date. Record the batch number of the product in the patient's medical record with each infusion. Bring factor XIII concentrate and diluent to RT. Place vial, diluent, and Mix2Vial transfer set on a flat surface. Remove flip caps on vial and diluent, and wipe stoppers with provided alcohol swab; allow to dry. Peel away the lid on the Mix2Vial transfer set, but leave it in the clear package. Hold the diluent vial tightly on a flat surface and pick up the Mix2Vial transfer set by its clear package. Push the plastic spike at the blue end of the Mix2Vial transfer set through the center of the diluent vial stopper. Carefully remove only the clear packaging from the transfer set. Invert the diluent vial with the Mix2Vial transfer set attached, and push the plastic spike of the transparent adapter firmly through the center of the factor XIII concentrate. Diluent will automatically transfer into the vial. With all parts still attached, gently swirl to fully dissolve. ***Do not shake.*** Solution should be colorless to slightly yellowish and slightly opalescent. Grasp the factor XIII side with one hand and the diluent side with the other and unscrew the set into 2 pieces. Draw air into an empty 20-mL sterile syringe. With the factor XIII vial upright, screw the syringe to the Mix2Vial transfer set. Inject air into the factor XIII vial. Keep the syringe plunger pressed, and invert the system upside down to draw the concentrate into the syringe by pulling the plunger back slowly. Keep the plunger facing down and remove syringe from transfer set. Attach the syringe to a suitable IV administration set. If the same patient is to receive more than one vial, contents of multiple vials may be pooled. Use a separate, unused Mix2Vial transfer set for each vial. Must be used within 4 hours of reconstitution.

Filters:

Mix2Vial filter transfer set provided.

Storage:

Protect from light; refrigerate vials and diluent in carton at 2° to 8° C (36° to 46° F). Do not freeze. Stable for 24 months up to the expiration date on the carton under refrigeration. May be stored at RT not to exceed 25° C (77° F) for up to 6 months; however, it cannot be returned to refrigeration. Mark date removed from refrigeration. Do not use beyond expiration date on carton and vial labels or beyond end of RT storage, whichever comes first. Must be used within 4 hours of reconstitution. Do not refrigerate or freeze the reconstituted solution. Contains no preservatives; a single-use vial; discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with other medicinal products, and administer through a separate infusion line.”

RATE OF ADMINISTRATION

Initial dose:

Do not exceed 4 mL/min.

ACTIONS

A heat-treated, lyophilized factor XIII (coagulation factor XIII) concentrate made from pooled human plasma. Several manufacturing steps are used to inactivate or remove both enveloped and nonenveloped viruses. Factor XIII circulates in blood and is present in platelets, monocytes, and macrophages. Activated factor XIII (factor XIIIa) promotes cross-linking of fibrin during coagulation and is essential to the physiologic protection of the clot against fibrinolysis. Cross-linked fibrin is the end result of the coagulation cascade and provides tensile strength to a primary hemostatic platelet plug. Half-life is approximately 6.6 ± 2.29 days. The increase in plasma levels of factor XIII after administration lasts approximately 28 days.

INDICATIONS AND USES

Routine prophylactic treatment of congenital factor XIII deficiency in adult and pediatric patients. To be effective, a trough factor XIII activity level of approximately 5% to 20% should be maintained.

Limitation of use:

There are no controlled trials demonstrating a direct benefit on treatment of bleeding episodes.

CONTRAINDICATIONS

Known anaphylactic or severe hypersensitivity reactions to human plasma–derived products or to any components of the product.

PRECAUTIONS

For IV use only. ■ Hypersensitivity reactions have occurred; emergency equipment, medications, and supplies must be available. ■ Neutralizing inhibitory antibodies against factor XIII have been detected in patients receiving factor XIII. ■ Thromboembolic complications have been reported. Assess benefit versus risk in pregnant women because of their hypercoagulable state and potential for increased risk of thromboembolic events. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection. ■ Consider appropriate vaccination against hepatitis A and B.

Monitor:

Monitor trough factor XIII activity levels as outlined in Usual Dose and Dose Adjustments. ■ Monitor for S/S of hypersensitivity reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for possible development of inhibitory antibodies (e.g., response to treatment is inadequate, expected plasma factor XIII activity levels are not attained, or breakthrough bleeding occurs). ■ Monitor for thromboembolic complications (e.g., chest pain, dyspnea, edema, hemoptysis, leg pain, or positive Homans' sign). ■ Monitor for S/S of viral infection (e.g., chills, drowsiness, fever, runny nose followed by joint pain and rash or abdominal pain, dark urine, jaundice, nausea, vomiting).

Patient Education:

Manufactured from pooled human plasma. Possibility of viral transmission exists. Promptly report S/S of viral infections (e.g., chills, drowsiness, fever, runny nose followed by joint pain and rash or abdominal pain, dark urine, jaundice, nausea, vomiting). ■ Promptly report difficulty breathing, pruritus, or rash. ■ Promptly report breakthrough bleeding.

Maternal/Child:

Category C: use only if clearly needed; see Precautions. ■ Use only if clearly needed in breast-feeding women. ■ No apparent differences in the safety profile in pediatric patients compared with adults. Pediatric patients under 16 years of age had a shorter half-life and faster clearance compared with adults.

Elderly:

Numbers in clinical studies insufficient to determine whether elderly patients respond differently than younger subjects.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most commonly reported side effects included arthralgia, chills, elevated thrombin-antithrombin levels, fever, headache, hypersensitivity reactions (including allergy, erythema, pruritus, and rash), and increased hepatic enzymes. Other reported side effects included abdominal pain, diarrhea, epistaxis, flu-like syndrome, hematoma, URT infection, and vomiting.

Post-Marketing:

Hypersensitivity reactions (including anaphylaxis), factor XIII inhibition (neutralizing antibodies), thrombotic events (e.g., embolism, thrombosis), viral infection (possible).

ANTIDOTE

Keep physician informed of side effects; most will be treated symptomatically. Discontinue administration and treat hypersensitivity reactions as indicated. A different lot may not cause a reaction. For thrombosis, anticoagulation may be indicated. Resuscitate as necessary.

FAMOTIDINE

(fah-**MOH**-tih-deen)
Famotidine PF, Pepcid
Antiulcer agent (H_2 antagonist)
Gastric acid inhibitor
pH 5.7 to 6.4

USUAL DOSE

20 mg every 12 hours. Increase frequency of dose, not amount, if necessary for pain relief. In hypersecretory states (e.g., Zollinger-Ellison syndrome), higher doses may be required. Adjust dose to individual patient needs.

PEDIATRIC DOSE

Age 1 to 16 years:

Starting dose is 0.25 mg/kg every 12 hours. Treatment duration and dose must be individualized based on clinical response, pH determination, and/or endoscopy. Doses up to 0.5 mg/kg every 12 hours may be required for gastric acid suppression. Another source suggests 0.6 to 0.8 mg/kg/24 hr (0.3 to 0.4 mg/kg every 12 hours or 0.2 to 0.27 mg/kg every 8 hours). May need to reduce interval to every 8 hours because of increased elimination. Maximum dose is 40 to 80 mg/24 hr based on diagnosis.

Neonate (unlabeled):

0.5 mg/kg/dose/24 hr.

DOSE ADJUSTMENTS

Reduce dose by one-half or increase the dosing interval to 36 to 48 hours in patients with moderate or severe renal dysfunction (CrCl less than 50 mL/min). Adjust based on patient response. Half-life may exceed 20 hours if CrCl less than 10 mL/min.

DILUTION

IV injection:

Available in vials containing 10 mg/mL and as premixed solution 20 mg/50 mL. Each 20-mg vial may be diluted with 5 to 10 mL of NS or other **compatible** infusion solutions for injection (e.g., D5W, D10W, LR, SWFI). Many references state famotidine may be administered undiluted.

Intermittent infusion:

Each 20 mg may be diluted in 100 mL of D5W or other **compatible** infusion solution and given piggyback.

Storage:

Refrigerate vials before dilution. Manufacturer recommends use of diluted solutions within 48 hours. However, studies suggest diluted solutions are physically and chemically stable at RT for 7 days. Store premixed Galaxy containers at CRT; avoid excessive heat. If solution freezes, bring to RT; allow sufficient time to solubilize.

COMPATIBILITY

May form a precipitate with sodium bicarbonate in concentrations greater than 0.2 mg/mL.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 20 mg or fraction thereof over at least 2 minutes.

Intermittent infusion:

Each 20-mg dose over 15 to 30 minutes.

ACTIONS

A histamine H_2 antagonist, it inhibits both daytime and nocturnal basal gastric acid secretion. It also inhibits gastric acid secretion stimulated by food and pentagastrin. Onset of action occurs within 30 minutes and lasts for 10 to 12 hours. No cumulative effect with repeated doses. 30 to 60 times more potent than cimetidine. Elimination half-life is 2.5 to 3.5 hours. Eliminated by renal and other metabolic routes. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Short-term treatment of active duodenal ulcers, benign gastric ulcers, and pathologic hypersecretory conditions in hospitalized patients or in patients unable to take oral medication. ■ Used orally for short-term treatment of gastroesophageal reflux disease (GERD), including erosive or ulcerative esophagitis.

Unlabeled uses:

GI bleeding. ■ Stress ulcer prophylaxis.

CONTRAINDICATIONS

Known hypersensitivity to H_2 receptor antagonists or their components; cross-sensitivity has occurred.

PRECAUTIONS

Use with caution in patients with moderate or severe renal dysfunction; see Dose Adjustments. ■ CNS adverse effects have been reported in patients with impaired renal function. ■ Gastric malignancy may be present even though patient is asymptomatic. ■ Effects maintained with oral dosage. Total treatment usually discontinued after 4 to 8 weeks.

Monitor:

Use antacids concomitantly to relieve pain. ■ See Precautions.

Patient Education:

Stop smoking or at least avoid smoking after last dose of the day. ■ Gastric pain and ulceration may recur after medication is stopped.

Maternal/Child:

Category B: use during pregnancy only when clearly needed. ■ Advisable to discontinue breast-feeding. ■ Plasma clearance is reduced and half-life is increased in pediatric patients under 3 months of age compared to older pediatric patients with pharmacokinetic parameters similar to adults.

Elderly:

Response similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out. ■ Consider risk of renal dysfunction; reduced doses and monitoring of renal function may be indicated; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May inhibit gastric absorption of **ketoconazole**. ■ May decrease **cyclosporine** serum levels when famotidine is given concurrently with ketoconazole and cyclosporine.

SIDE EFFECTS

Constipation, diarrhea, dizziness, and headache are the most common side effects. Hypersensitivity reactions (bronchospasm, fever, pruritus, rash, eosinophilia) can occur. Abdominal discomfort, agitation, alopecia, anorexia, anxiety, arthralgias, confusion, decreased libido, depression, dry mouth, dry skin, elevated ALT, flushing, grand mal seizure, hallucinations, insomnia, interstitial pneumonia, malaise, muscular pain, nausea and vomiting, orbital edema, palpitations, paresthesias, somnolence, taste disorder, thrombocytopenia, tinnitus, and toxic epidermal necrolysis/Stevens-Johnson syndrome (very rare) have been reported. Convulsions in patients with impaired renal function have been reported rarely.

ANTIDOTE

Notify physician of all side effects. May be treated symptomatically or may respond to decrease in frequency of dosage. Resuscitate as necessary for overdosage.

FAM-TRASTUZUMAB DERUXTECAN-nxki BBW

(fam-trast-**TU**-zoo-mab de-**RUX**-teh-can nxki)
Enhertu
Antineoplastic
HER2-directed antibody
Topoisomerase inhibitor conjugate
pH 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

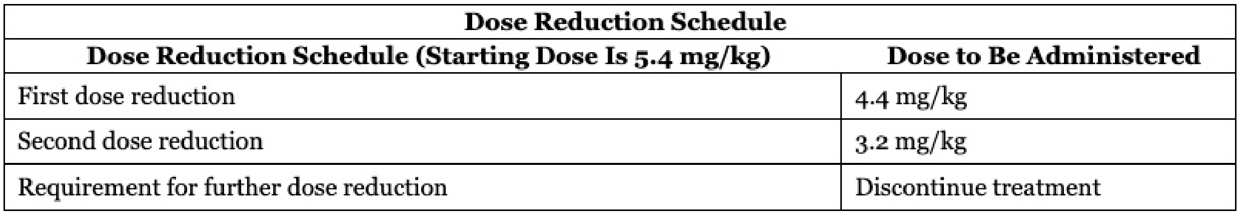
Fam-trastuzumab deruxtecan-nxki:

5.4 mg/kg given as an IV infusion once every 3 weeks (21-day cycle) until disease progression or unacceptable toxicity. ***DO NOT substitute fam-trastuzumab deruxtecan-nxki for or with trastuzumab or ado-trastuzumab emtansine.***

DOSE ADJUSTMENTS

No dose adjustment required in patients with mild (creatinine clearance [CrCl] 60 to less than 90 mL/min) or moderate (CrCl 30 to less than 60 mL/min) renal impairment.

No data available in patients with severe renal impairment. ■ No dose adjustment is required in patients with mild hepatic impairment (total bilirubin less than or equal to the ULN and any AST greater than the ULN or total bilirubin 1 to 1.5 times the ULN and any AST) or moderate hepatic impairment (total bilirubin 1.5 to 3 times the ULN and any AST). No data available in patients with severe hepatic impairment (total bilirubin 3 to 10 times the ULN and any AST). ■ No dose adjustment required based on age, race, sex, or body weight. ■ Management of side effects may require temporary interruption, dose reduction, or treatment discontinuation. ■ ***Do not re-escalate the fam-trastuzumab deruxtecan-nxki dose after a dose reduction is made.*** ■ If a planned dose is delayed or missed, administer as soon as possible. Adjust the schedule of administration to maintain a 3-week interval between doses. Administer infusion at the dose and rate the patient tolerated most recently.



Dose Reduction Schedule	
Dose Reduction Schedule (Starting Dose Is 5.4 mg/kg)	**Dose to Be Administered**
First dose reduction	4.4 mg/kg
Second dose reduction	3.2 mg/kg
Requirement for further dose reduction	Discontinue treatment

Dose Modifications for Adverse Reactions		
Adverse Reaction	**Severity**	**Treatment Modification**
Interstitial lung disease (ILD)/pneumonitis	Asymptomatic ILD/pneumonitis (Grade1)	Interrupt fam-trastuzumab deruxtecan-nxki until resolved to Grade 0, then: • If resolved in 28 days or less from date of onset, maintain dose. • If resolved in more than 28 days from date of onset, reduce dose one level. • Consider corticosteroid treatment as soon as ILD/pneumonitis is suspected.
	Symptomatic ILD/pneumonitis (Grade 2 or greater)	Permanently discontinue fam-trastuzumab deruxtecan-nxki. Promptly initiate corticosteroid treatment as soon as ILD/pneumonitis is suspected.
Neutropenia	Grade 3 (<1 to 0.5×10^9/L)	Interrupt fam-trastuzumab deruxtecan-nxki until resolved to Grade 2 or less, then maintain dose.
	Grade 4 ($<0.5 \times 10^9$/L)	Interrupt fam-trastuzumab deruxtecan-nxki until resolved to Grade 2 or less. Reduce dose by one level.
Febrile neutropenia	Absolute neutrophil count of $<1 \times 10^9$/L and temperature greater than 38.3° C (101° F) or a sustained temperature of 38° C (100.4° F) or greater for more than 1 hour.	Interrupt fam-trastuzumab deruxtecan-nxki until resolved. Reduce dose by one level.

Left ventricular dysfunction	LVEF >45% and absolute decrease from baseline is 10% to 20%		Continue treatment with fam-trastuzumab deruxtecan-nxki.
	LVEF 40% to 45%	And absolute decrease from baseline is <10%	Continue treatment with fam-trastuzumab deruxtecan-nxki. Repeat LVEF assessment within 3 weeks.
		And absolute decrease from baseline is 10% to 20%	Interrupt fam-trastuzumab deruxtecan-nxki. Repeat LVEF assessment within 3 weeks. If LVEF has not recovered to within 10% from baseline, permanently discontinue fam-trastuzumab deruxtecan-nxki. If LVEF recovers to within 10% from baseline, resume treatment with fam-trastuzumab deruxtecan-nxki at the same dose.
	LVEF <40% or absolute decrease from baseline is >20%		Interrupt fam-trastuzumab deruxtecan-nxki. Repeat LVEF assessment within 3 weeks. If LVEF of <40% or absolute decrease from baseline of >20% is confirmed, permanently discontinue fam-trastuzumab deruxtecan-nxki.
	Symptomatic congestive heart failure (CHF)		Permanently discontinue fam-trastuzumab deruxtecan-nxki.

Toxicity grades are in accordance with National Cancer Institute Common Terminology Criteria for Adverse Events Version 4.03 (NCI-CTCAE v.4.03).

DILUTION

Specific techniques required; see Precautions. Check vial labels to ensure use of fam-trastuzumab deruxtecan-nxki and **NOT** trastuzumab or ado-trastuzumab emtansine. Available in a 100-mg single-dose vial. Calculate the dose in mg, the volume of fam-trastuzumab deruxtecan-nxki solution required, and the number of vial(s) needed. Reconstitute each 100-mg vial by slowly injecting 5 mL of SWFI into each vial to yield a concentration of 20 mg/mL. Swirl vial gently; ***do not shake***. Solution should be clear and colorless to light yellow. Must be further diluted in D5W by withdrawing the calculated volume from each vial(s) and transferring to an infusion bag of 100 mL of D5W. ***Do not use NaCl injection***. Gently invert bag to mix. ***Do not shake***. Cover the infusion bag to protect from light. Immediate use preferred.

Filters:

Use of 0.2- or 0.22-micron, in-line polyethersulfone (PES) or polysulfone (PS) filter required for administration.

Storage:

Store vials in refrigerator at 2° to 8° C (36° to 46° F) in original carton to protect from light. ***Do not freeze. Do not shake reconstituted or diluted solutions.*** Reconstituted vials should be used immediately but may be stored for up to 24 hours in a refrigerator at 2° to 8° C (36° to 46° F). Diluted solution should also be used immediately but can be stored at RT for up to 4 hours (including preparation and infusion) or in a refrigerator at 2° to 8° C (36° to 46° F) for up to 24 hours. ***Do not freeze reconstituted or diluted solutions,*** and protect from light. Discard unused reconstituted drug, and any portion left in the vial, after 24 hours.

COMPATIBILITY

Manufacturer states, "Do not mix fam-trastuzumab deruxtecan-nxki with other drugs or administer other drugs through the same intravenous line." Is **compatible** with an infusion bag made of polyvinylchloride or polyolefin (copolymer of ethylene and polypropylene). **Incompatible** with NS.

RATE OF ADMINISTRATION

For IV infusion only. ***Do not administer as an IV push or bolus***. Use of an infusion set made of polyolefin or polybutadiene and a 0.2- or 0.22-micron, in-line polyethersulfone (PES) or polysulfone (PS) filter required. If the prepared infusion solution was stored refrigerated, allow the solution to reach RT before administration. Slow or interrupt the infusion rate if the patient develops infusion-related symptoms. See Antidote.

First infusion:

Administer a single dose equally distributed over 90 minutes.

Subsequent infusions:

If initial and/or prior infusions are well tolerated, subsequent infusions may be administered equally distributed over 30 minutes.

ACTIONS

A HER2-directed antibody-drug conjugate. The antibody is a humanized anti-HER2 IgG1 antibody. The small molecule, DXd, is a topoisomerase I inhibitor attached to the antibody by a cleavable linker. Following binding to HER2 on tumor cells, fam-trastuzumab deruxtecan-nxki undergoes internalization and intracellular linker cleavage by lysosomal enzymes. Upon release, the membrane-permeable DXd causes DNA damage and apoptotic cell death. The humanized HER2 IgG1 monoclonal antibody is expected to be degraded into small peptides and amino acids via catabolic pathways in the same manner as endogenous IgG. In vitro, DXd is primarily metabolized by CYP3A4. The elimination half-life of fam-trastuzumab deruxtecan-nxki is approximately 5.7 days. The median apparent elimination half-life of DXd is 5.8 days.

INDICATIONS AND USES

Treatment of adult patients with unresectable or metastatic HER2-positive breast cancer who have received two or more prior anti-HER2 based regimens in the metastatic setting. This indication is approved under accelerated approval based on tumor response rate and duration of response. Continued approval for this indication may be contingent upon verification and description of clinical benefit in a confirmatory trial.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ ***Do not substitute fam-trastuzumab deruxtecan-nxki for or with trastuzumab or ado-trastuzumab emtansine***. ■ Severe, life-threatening interstitial lung disease (ILD) and pneumonitis, including fatal cases, have occurred. ■ Severe neutropenia, including febrile neutropenia, has occurred. ■ Patients may be at an increased risk for developing left ventricular dysfunction. Left ventricular ejection fraction (LVEF) decrease has been observed. ■ Exposure to fam-trastuzumab deruxtecan-nxki during pregnancy can result in embryo-fetal harm; see Patient Education and Maternal/Child. ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ Has not been studied in severe renal or hepatic function.

Monitor:

Monitor complete blood counts before initiation of fam-trastuzumab deruxtecan-nxki, before each dose, and as clinically indicated. Depending on the severity of neutropenia, treatment may require dose interruption or reduction. ■ Assess LVEF before initiation of fam-trastuzumab deruxtecan-nxki and at regular intervals during treatment as clinically indicated. Manage LVEF decrease through treatment interruption; see Dose Adjustments. ■ Monitor for and promptly investigate S/S interstitial lung disease/pneumonitis, including cough, dyspnea, fever, and other new or worsening respiratory symptoms. Evaluate patients with suspected ILD by radiographic imaging. Consider consultation with a pulmonologist. For asymptomatic (Grade 1) ILD, consider corticosteroid treatment (e.g., 0.5 mg/kg or more of prednisolone or equivalent) and withhold further therapy until recovery. In cases of symptomatic ILD (Grade 2 or greater), promptly discontinue further therapy and initiate corticosteroid treatment (e.g., 1 mg/kg or more prednisolone or equivalent). On improvement, follow by gradual taper over 4 weeks. ■ Due to potentially increased exposure, closely monitor patients with moderate hepatic impairment for increased toxicities related to the topoisomerase inhibitor DXd. ■ See Antidote.

Patient Education:

Read FDA-approved Medication Guide. ■ Can cause embryo-fetal harm; Advise females of reproductive potential to use effective contraception during treatment and for at least 7 months after the last dose. Advise male patients with female partners of reproductive potential to use effective contraception during treatment and for at least 4 months after the last dose. ■ Advise female patients to contact health care provider of a known or suspected pregnancy. ■ May impair male reproductive function and fertility. ■ Immediately report any cough, dizziness, fatigue, fever, loss of consciousness, palpitations, shortness of breath or other new or worsening respiratory symptoms, S/S of infection, sudden weight gain, or swelling of the ankles/legs. ■ See Appendix D.

Maternal/Child:

Avoid pregnancy. Based on mechanism of action, fam-trastuzumab-nxki can cause fetal harm when administered to a pregnant woman. If fam-trastuzumab deruxtecan-nxki is administered during pregnancy or within 7 months before conception, monitor for oligohydramnios. ■ Do not breast-feed during treatment and for 7 months after the last dose. ■ Safety and effectiveness have not been established for use in pediatric patients.

Elderly:

No overall differences in efficacy were observed between patients 65 years of age or older and younger patients. A higher incidence of Grade 3 to 4 adverse reactions was observed in patients 65 years of age or older compared with younger patients.

DRUG/LAB INTERACTIONS

Coadministration of itraconazole (a strong CYP3A inhibitor) and ritonavir (a dual inhibitor of OATP1B/CYP3A) did not have a clinically significant impact. ■ DXd is a substrate of OATP1B1, OATP1B3, MATE2-K, P-gp, MRP1, and BCRP.

SIDE EFFECTS

Alopecia, anemia, constipation, cough, decreased appetite, diarrhea, fatigue, leukopenia, nausea, neutropenia, thrombocytopenia, and vomiting were most common. Abdominal pain, dizziness, dry eye, dyspepsia, dyspnea, epistaxis, febrile neutropenia, headache, hemoglobin decrease, hypokalemia, increased AST and ALT, infusion-related reactions, interstitial lung disease, rash, stomatitis, upper respiratory tract infection, and WBC count decrease have also been reported.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Slow or interrupt the infusion rate if patient develops infusion-related symptoms and treat appropriately. Permanently discontinue treatment in case of severe infusion reactions. Permanently discontinue treatment in all patients with Grade 2 or higher ILD/pneumonitis. Permanently discontinue treatment if LVEF less than 40% or if patient develops symptomatic congestive heart failure (CHF). Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. Resuscitate as indicated.

FAT EMULSION, INTRAVENOUS BBW

Clinolipid 20%, Intralipid 20% & 30%, Liposyn II 10% & 20%, Nutrilipid 20%
Nutritional supplement (fatty acid)
pH 6 to 8.9

USUAL DOSE

Dose depends on energy expenditure and on patient’s clinical status, body weight, tolerance, and ability to metabolize fat emulsion. For partial parenteral nutrition, energy supplied by oral or enteral nutrition must be taken into account. Some solutions may contain aluminum; see Precautions.

Caloric source (as a component of parenteral nutrition):

Initial dose: 1 to 1.5 Gm/kg/day (not to exceed 500 mL of Intralipid 20% on the first day). ***Maximum daily dose:*** 2.5 Gm/kg/day. Do not exceed 60% of the patient's total caloric intake. Amino acids and carbohydrates should account for the remaining caloric input.

Essential fatty acid deficiency (Intralipid and Nutrilipid):

8% to 10% of the caloric input should be supplied as a fat emulsion to provide adequate amounts of essential fatty acids; see Dose Adjustments.

PEDIATRIC DOSE

Some solutions may contain aluminum; see Precautions. The American Society of Enteral and Parenteral Nutrition recommends the following doses for pediatric patients.

Caloric source (as a component of parenteral nutrition):

Infants (preterm and term to less than 1 year of age): 1 to 2 Gm/kg/day as an initial dose. Increase dose by 0.5 to 1 Gm/kg/day each day to a maximum daily dose of 3 Gm/kg/day. Infuse daily dose over 24 hours. ***Pediatric patients (1 to 10 years of age):*** 1 to 2 Gm/kg/day as an initial dose. Increase dose by 0.5 to 1 Gm/kg/day each day to a maximum daily dose of 2 to 3 Gm/kg/day. Infuse daily dose over 24 hours. ***Adolescents:*** 1 Gm/kg/day as an initial dose (not to exceed 500 mL of Intralipid 20% on the first day). Increase dose by 1 Gm/kg/day each day to a maximum daily dose of 2.5 Gm/kg/day. Infuse daily dose over 12 to 24 hours.

Do not exceed 60% of total caloric intake. Amino acids and carbohydrates should account for the remaining caloric input.

Premature infants:

Intralipid: Treatment of premature and low-birth-weight infants must be based on careful benefit-risk assessment. Strict adherence to the recommended total daily dose is mandatory. Hourly infusion rate should be as slow as possible. Never exceed 1 Gm/kg in 4 hours. Begin with 0.5 Gm fat/kg/24 hr (2.5 mL/kg/24 hr of 20% solution). May be increased based on infant's ability to eliminate fat. See comments under Pediatric Dose, Rate of Administration, Precautions, and Maternal/Child. ***Nutrilipid:*** See infant dose.

Essential fatty acid deficiency:

See Usual Dose and Dose Adjustments.

DOSE ADJUSTMENTS

Lower initial starting doses and smaller incremental advances are suggested in patients with elevated triglyceride levels. Checking of triglycerides is recommended before each incremental advance. ■ If essential fatty acid deficiency occurs together with stress, dose may need to be increased. ■ Reduce dose in patients who develop serum triglyceride concentrations above 400 mg/dL to prevent consequences associated with hypertriglyceridemia. (Serum triglyceride levels above 1,000 mg/dL have been associated with an increased risk of pancreatitis.)

DILUTION

Follow manufacturer's specific instructions for preparation of each individual brand. Must be given as prepared by manufacturer; check labels for aluminum content; see Precautions. Do not use if there appears to be an oiling out of the emulsion. **Intralipid 30% is not to be given by direct IV infusion.** Packaged for bulk use in a pharmacy admixture program. Must be specifically combined with dextrose solutions and amino acids (TPN) so total fat content does not exceed 20%. When combined with dextrose, check mixture closely for the presence of precipitates. Prepared for an individual patient in the pharmacy.

Filters:

Do not use filters of less than 1.2 microns with lipid emulsions. Use of a 1.2-micron in-line filter during administration (alone or as part of an admixture) is recommended.

Storage:

Must be stored at temperatures not exceeding 25° C (77° F). Specific storage conditions required (see literature). Do not freeze. Use only freshly opened solutions; discard remainder of partial dose.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Lipids may extract phthalates from phthalate-plasticized PVC (DEHP). Non-phthalate infusion sets recommended.

Manufacturer recommends not mixing with any electrolyte or other nutrient solution. Infuse separately; do not disturb emulsion; no additives or medications are to be placed in bottle or tubing with the exception of heparin 1 to 2 units/mL (may be added before administration [activates lipoprotein lipase]). In actual practice, carbohydrates, amino acids, and fat emulsion are mixed in specific percentages and in a specific order to meet individual total parenteral nutritional needs but should be prepared in the pharmacy. Any addition of supplemental vitamins, minerals, or electrolytes (e.g., calcium, magnesium, phosphates) may cause a precipitate unless a specific order is followed. Precipitates are difficult to detect in lipids. The prime destabilizers of emulsions are excessive acidity (such as pH below 5) and inappropriate electrolyte content. Divalent cations (calcium and magnesium) have been shown to cause emulsion instability. Amino acid solutions exert buffering effects that protect the emulsion.

RATE OF ADMINISTRATION

May be infused through a peripheral or central line. Lipids may extract phthalates from phthalate-plasticized PVC (DEHP). Non-phthalate infusion sets recommended.

May be administered via a Y-tube or three-way stopcock near the infusion site. Rates of both solutions (fat emulsion and amino acid products) should be controlled by infusion pumps.

Do not hang flexible plastic containers in series connection, do not pressurize to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets. All may result in air embolism. In general, administration rate should be adjusted taking into account the dose being administered, the daily volume intake, and the duration of the infusion. Most doses are administered over 12 to 24 hours.

Adult:

20%: 0.5 mL/min or 0.1 Gm fat/min for the first 15 to 30 minutes. If no untoward effects after 30 minutes, the rate may be increased gradually to the required rate (***Nutrilipid:*** 0.5 mL/kg/hr).

Premature infants:

Intralipid: 0.5 Gm fat/kg/24 hr (2.5 mL of 20%/kg/24 hr). Hourly infusion rate should be as slow as possible. Adjust rate and/or increase amount based on the infant's ability to eliminate fat. ***Nutrilipid:*** Initial rate of 0.05 mL/min for the first 10 to 15 minutes. If no untoward effects, rate may be increased to 0.75 mL/kg/hr. Never exceed 1 Gm/kg in 4 hours. See comments under Usual Dose and Maternal/Child.

Pediatric:

Intralipid: Initial rate of 0.05 mL/min for the first 10 to 15 minutes. If no untoward effects, rate may be increased to 0.5 mL/kg/hr. ***Nutrilipid:*** Initial rate of 0.05 mL/min for the first 10 to 15 minutes. If no untoward effects, rate may be increased to 0.75 mL/kg/hr (1 to 10 years of age) or 0.5 mL/kg/hr (over 10 years of age).

ACTIONS

An isotonic nutrient that serves as an important substrate for energy production. Used as a source of calories and essential fatty acids. Fatty acids are important for membrane structure and function as precursors for bioactive molecules (e.g., prostaglandins) and as regulators of gene expression. Total caloric value (fat, phospholipid, and glycerol) is 1.1 cal/mL for the 10% emulsion and 2 cal/mL for the 20% emulsion. The various formulations contain different components (see manufacturer's prescribing information for actual ingredients). The fatty acids, phospholipids, and glycerol found in lipid emulsions are metabolized by cells to carbon dioxide and water. This metabolism results in the generation of energy. Increases heat production and oxygen consumption. Decreases respiratory quotient. Some lipids are excreted through the biliary system.

INDICATIONS AND USES

To provide additional calories and essential fatty acids for patients requiring parenteral nutrition who will be receiving parenteral nutrition over extended periods (usually over 5 days) or when oral or enteral nutrition is not possible, is insufficient, or is contraindicated. ■ To prevent essential fatty acid deficiency (Intralipid and Nutrilipid only).

Limitation of use:

Clinolipid is not indicated for use in pediatric patients because there are insufficient data to demonstrate that it provides sufficient amounts of essential fatty acids in this population.

CONTRAINDICATIONS

Severe hyperlipidemia (serum triglycerides above 1,000 mg/dL) or severe disorders of lipid metabolism, such as pathologic hyperlipemia, lipoid nephrosis, and acute pancreatitis with hyperlipemia. ■ Known hypersensitivity to any component in the product (e.g., ***Clinolipid*** and ***Nutrilipid***: egg or soybean proteins).

PRECAUTIONS

Isotonic; may be administered by a peripheral vein or central venous infusion; when administered with dextrose and amino acids, choice of peripheral or central vein is based on osmolarity of the final infusate. ■ Fatty acids displace bilirubin bound to albumin. Use caution in jaundiced or premature infants. ■ Deaths in preterm infants have been reported; see Maternal/Child. ■ Use caution in pulmonary disease, liver disease, anemia, or blood coagulation disorders or when there is any danger of fat embolism. ■ Patients requiring parenteral nutrition may be at higher risk for infection due to malnutrition, underlying disease state, and/or catheter access. ■ Hypersensitivity reactions are possible. ■ Fat overload syndrome has been reported (rare); see Monitor. ■ Parenteral nutrition–associated liver disease has been reported with use for extended periods of time, especially in preterm infants. May present as cholestasis or steatohepatitis. ■ Administration of parenteral nutrition to severely undernourished patients may result in refeeding syndrome. Initiate parenteral nutrition therapy slowly and monitor closely. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ See Maternal/Child.

Monitor:

Monitor lipids routinely; lipemia should clear daily. ■ Correct severe water and electrolyte disorders, severe fluid overload states, and severe metabolic disorders before administration. ■ Obtain baseline values and monitor blood glucose, fluid and electrolyte status, blood coagulation, liver and kidney function, triglycerides, CBC and platelet count, and serum osmolarity as indicated, especially in neonates. Discontinue use for significant abnormality. ■ Monitor for S/S of hypersensitivity (e.g., altered mentation, bronchospasm, chills, cyanosis, dizziness, dyspnea, erythema, fever, flushing, headache, hypotension, hypoxia, nausea, rash, sweating, tachycardia, tachypnea, urticaria, vomiting). ■ Monitor for S/S of infection. ■ Monitor for S/S of fat overload syndrome. Reduced or limited ability to metabolize and clear lipids may result in a sudden deterioration of patient condition accompanied by anemia, coagulation disorders, deteriorating liver function, fever, hepatomegaly, hyperlipidemia, leukopenia, thrombocytopenia, and CNS manifestations (e.g., coma). ■ For severely undernourished patients initiating parenteral nutrition therapy, monitor closely for S/S of refeeding syndrome. May be characterized by the intracellular shift of potassium, phosphorus, and magnesium; thiamine deficiency; and fluid retention. ■ Monitor for S/S of essential fatty acid deficiency. ■ Monitor catheter site. ■ See Maternal/Child.

Patient Education:

Inform parents that deaths in premature infants after infusion of IV fat emulsion have been reported. ■ Laboratory monitoring is required. ■ Promptly report any S/S of hypersensitivity reactions (e.g., bronchospasm, chills, dyspnea, hypotension, hypoxia, nausea, rash, urticaria). ■ Promptly report any S/S of infection (e.g., fever, chills, pain at infusion site). ■ Review other possible side effects.

Maternal/Child:

Category C: use in pregnancy only when clearly needed; safety not established. Severe malnutrition in a pregnant woman is associated with preterm delivery, low birth weight, intrauterine growth restriction, congenital malformations, and perinatal mortality. Parenteral nutrition should be considered if a pregnant woman's nutritional requirements cannot be fulfilled by oral or enteral intake. ■ Use caution if fat emulsion is administered to a woman who is breast-feeding. ■ Use extreme caution in neonates; death from intravascular fat accumulation in the lungs has occurred. Strict adherence to dose and rate of administration is imperative. Premature and small-for-gestational-age infants have poor clearance. Administration of less than the maximum recommended dose should be considered in these patients to decrease the likelihood of intravenous fat overload. Monitor serum triglycerides and/or plasma free fatty acid levels to assess infant's ability to eliminate infused fat from the circulation; must clear between daily infusions. Frequent, even daily, platelet counts are recommended in neonatal patients receiving TPN with IV fat emulsion. ***Clinolipid:*** Safety and effectiveness for use in pediatric patients, including preterm infants, have not been established. Use in pediatric patients is not recommended.

Elderly:

Clinolipid and Nutrilipid: No overall differences in safety and/or effectiveness. Dose selection should be cautious, usually starting at the low end of the dosing range.

DRUG/LAB INTERACTIONS

Intralipid:

No specific information available; see Dilution. ***Clinolipid:*** Drug interaction studies not performed. ■ Olive and soybean oils contain vitamin K_1. May decrease the anticoagulant activity of **coumarin derivatives** (e.g., warfarin). ■ May interfere with certain **lab tests** if samples are taken before the lipids are eliminated from the serum (5 to 6 hours).

SIDE EFFECTS

Intralipid:

Back pain, chest pain, cyanosis, dizziness, dyspnea, flushing, headache, hypercoagulability, hyperlipemia, hypersensitivity reactions, hyperthermia, irritation at injection site, nausea and vomiting, sepsis (from contamination of IV catheter), sleepiness, slight pressure over eyes, sweating, thrombophlebitis (from concurrent parenteral nutrition fluids), thrombocytopenia in neonates (rare), and transient increase in liver enzymes may occur.

Clinolipid:

Abnormal liver function tests, hyperglycemia, hyperlipidemia, hypoproteinemia, nausea, and vomiting were most common. Hypersensitivity, infectious complications (e.g., fever of unknown origin, septicemia, UTI), and refeeding syndrome have been reported.

All formulations with long-term therapy:

Abnormal liver function tests, hepatomegaly, jaundice due to central lobular cholestasis, leukopenia, overloading syndrome, splenomegaly, thrombocytopenia, and deposition of brown pigment in the reticuloendothelial tissue of the liver may occur.

Post-Marketing:

Diarrhea, pruritus.

ANTIDOTE

Notify physician of all side effects. Many will be treated symptomatically. Treat hypersensitivity reactions promptly and resuscitate as necessary. For accidental overdose, stop the infusion. Obtain blood sample for inspection of plasma, triglyceride concentration, or measurement of plasma light-scattering activity by nephelometry. Repeat blood samples until the lipid has cleared. Stop infusion immediately for any signs of acute respiratory distress. May represent pulmonary embolus or interstitial pneumonitis, which may be caused by an unseen precipitate of electrolytes (e.g., calcium and phosphates) in the solution. Lipids administered and fatty acids produced are not dialyzable.

FENOLDOPAM MESYLATE

(feh-**NOL**-doh-pam **MES**-ih-layt)
Corlopam
Antihypertensive
Vasodilator

USUAL DOSE

Initiate dosing at 0.01 to 0.3 mcg/kg/min as a continuous infusion. Titrate in increments of 0.05 to 0.1 mcg/kg/min every 15 minutes or longer until target blood pressure is reached. The maximum infusion rate reported in clinical studies was 1.6 mcg/kg/min. Doses lower than 0.1 mcg/kg/min and slow up-titration have been associated with less reflex tachycardia. Maintenance infusions may be continued for up to 48 hours. Transition to oral therapy with another agent can begin any time after blood pressure is stable during fenoldopam infusion. Avoid hypotension and rapid decreases in BP.

PEDIATRIC DOSE

Initiate dosing at 0.2 mcg/kg/min as a continuous infusion. Titrate dose by 0.3 to 0.5 mcg/kg/min every 20 to 30 minutes to a maximum dose of 0.8 mcg/kg/min. Higher doses generally produced no further decreases in mean arterial pressure (MAP) but did worsen tachycardia. See Maternal/Child.

DOSE ADJUSTMENTS

Dose adjustment is not required in end-stage renal disease; in patients on continuous ambulatory peritoneal dialysis (CAPD); in severe hepatic failure; or by age, gender, or race. Effects of hemodialysis have not been evaluated. ■ Caution and lower-end dosing suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 10 mg (1 mL) must be diluted with 250 mL of NS or D5W and given as a continuous infusion. (10 mg in 250 mL, 20 mg in 500 mL, or 40 mg in 1,000 mL all yield 40 mcg/mL.) Use of an infusion pump is recommended.

Pediatric dilution:

Mix to yield a final concentration of 60 mcg/mL (6 mg in 100 mL, 15 mg in 250 mL, or 30 mg in 500 mL of D5W or NS). Use of an infusion pump capable of delivering low infusion rates is required.

Storage:

Store unopened ampules or vials at 2° to 30° C (35.6° to 86° F). Discard diluted solution if not being administered to a patient after 4 hours at RT or after 24 hours refrigerated.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not give as a bolus injection; must be given as an infusion. See Usual Dose and Pediatric Dose for recommended initial infusion rate, titration, and maximum recommended infusion rate. Use of an infusion pump is recommended. To calculate the infusion rate in mL/hr, use the following formula:

$$\text{Infusion rate (mL/hr)} = \frac{[\text{Dose (mcg/kg/min)} \times \text{Weight (kg)} \times 60\ \text{min/hr}]}{\text{Concentration (mcg/mL)}}$$

Example: For a 60-kg patient at an initial dose of 0.01 mcg/kg/min using the 40 mcg/mL concentration, the infusion rate would be:

$$\text{Infusion rate (mL/hr)} = \frac{[0.01\ \text{mcg/kg/min} \times 60\ \text{kg} \times 60\ \text{min/hr}]}{40\ \text{mcg/mL}} = 0.9\ \text{mL/hr}$$

Avoid hypotension and rapid decreases in BP. Manufacturer's prescribing information contains charts of infusion rates per hour for a range of doses and a range of weights for both adult and pediatric patients.

ACTIONS

A peripherally acting rapid-acting vasodilator. Is an agonist at the D_1 receptor and binds with moderate affinity to the alpha_2 adrenoreceptor. Causes a dose-dependent fall in systolic and diastolic BP. May cause a reflex increase in HR. Decreases peripheral vascular resistance. Increases renal blood flow, diuresis, and natriuresis. Onset of action begins within 5 minutes, and with continuous infusion, steady-state concentrations (peak effects) are reached in 15 to 20 minutes. Elimination half-life is about 5 minutes. Metabolized in the liver primarily by conjugation (without cytochrome P_{450} enzymes). Primarily eliminated in urine; some excretion in feces.

INDICATIONS AND USES

Adult patients:

In-hospital, short-term (up to 48 hours) management of severe hypertension when rapid, but quickly reversible, emergency reduction of BP is indicated, including malignant hypertension with deteriorating end-organ function.

Pediatric patients:

In-hospital, short-term (up to 4 hours) for reduction in BP.

Unlabeled uses:

Renal protection before study with contrast dye.

CONTRAINDICATIONS

Manufacturer states, "None known."

PRECAUTIONS

Use limited to the hospital. Adequate personnel and appropriate equipment must be available for continuous monitoring. ■ Use extreme caution in patients with open-angle glaucoma or intraocular hypertension. Has caused a dose-dependent increase in intraocular pressure. Upon discontinuation of fenoldopam, intraocular pressure returned to baseline values within 2 hours. ■ Causes a dose-related tachycardia with infusion rates above 0.1 mcg/kg/min in adults. May diminish over time in adults but is consistent at higher doses. Has not been reported but could lead to ischemic cardiac events or worsened heart failure. ■ Tachycardia occurred in pediatric patients at doses greater than or equal to 0.8 mcg/kg/min. ■ Rapidly decreases serum potassium leading to hypokalemia; see Monitor. ■ Use caution; contains sulfites. Sulfite sensitivity is seen more frequently in asthmatic individuals. ■ See Drug/Lab Interactions.

Monitor:

Determine patency of vein; avoid extravasation. ■ Monitor BP and HR frequently, especially during titration. Avoid hypotension. ■ Monitor serum electrolytes frequently; hypokalemia has been observed after less than 6 hours of fenoldopam infusion. Oral or intravenous supplements may be required. ■ Transfer to oral antihypertensive agents when BP is stable. May be added during fenoldopam infusion or following its discontinuation; monitor effects carefully. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Report IV site burning or stinging promptly. ■ Request assistance with ambulation.

Maternal/Child:

Category B: use only if clearly needed. ■ Discontinue breast-feeding; not known if fenoldopam is secreted in breast milk (is secreted in milk of rats). ■ Antihypertensive effects have been studied in pediatric patients under 1 month of age (at least 2 kg or full term) to 12 years of age. Pharmacokinetics are independent of age when corrected for body weight. Clinical studies did not include adolescents (12 to 16 years of age). Dose selection for this group should consider clinical condition and concomitant drug therapy.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ Response similar to other age-groups.

DRUG/LAB INTERACTIONS

No specific drug interaction studies have been conducted. ■ Concurrent use not recommended with **beta-adrenergic blocking agents**. May cause unexpected hypotension from beta-blocker inhibition of the reflex response to fenoldopam (e.g., tachycardia). Monitor BP frequently if concurrent use is required.

SIDE EFFECTS

Dose-dependent side effects may include hypotension with resulting tachycardia, flushing, headache, and nausea. Additional side effects unrelated to dose include abdominal pain or fullness; angina; anxiety; cardiac failure; chest pain; diaphoresis; diarrhea; dizziness; ECG T-wave inversion; extrasystoles; fever; hypokalemia; increased BUN, SCr, glucose, transaminases, and lactate dehydrogenase; injection site reaction; insomnia; ischemic heart disease; muscle spasm; MI; nasal congestion; nervousness; oliguria; palpitations; postural hypotension; urinary infection; and vomiting.

Post-Marketing:

Abdominal distension, cardiogenic shock, decreased oxygen saturation, ECG ST-segment depression, hypotension.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. Use oral and/or intravenous potassium to treat hypokalemia. Reduce dose gradually as desired BP is reached. Discontinue fenoldopam immediately for excessive hypotension. Half-life is short. Recovery should begin within 5 to 15 minutes; support patient as indicated (e.g., Trendelenburg position, IV fluids if appropriate). With short half-life the need for vasopressors is unlikely. Discontinue fenoldopam and treat life-threatening arrhythmias as indicated.

FENTANYL CITRATE BBW

(**FEN**-tah-nil **SIT**-rayt)
Fentanyl, Fentanyl Citrate PF
Opioid analgesic (agonist)
Anesthesia adjunct
pH 4 to 7.5

USUAL DOSE

Pretreatment:

See Maternal/Child.

Dose should be individualized, taking into account factors such as age, body weight, physical status, concomitant drugs or diseases, type of anesthesia to be used, and type of surgery or procedure to be performed. In all situations, use smallest effective dose at maximum intervals.

Premedication in adults:

50 to 100 mcg (0.05 to 0.1 mg) IM or IV 30 to 60 minutes before surgery.

Adjunct to regional anesthesia:

50 to 100 mcg (0.05 to 0.1 mg) IM or IV slowly over 1 to 2 minutes when additional analgesia is required.

Adjunct to general anesthesia:

Low dose:

2 mcg/kg (0.002 mg/kg) of body weight. Additional doses are usually not necessary for these minor procedures.

Moderate dose:

2 to 20 mcg/kg (0.002 to 0.02 mg/kg) of body weight. Additional doses of 25 to 100 mcg may be administered as needed.

High dose:

20 to 50 mcg/kg (0.02 to 0.05 mg/kg) of body weight. Additional doses from 25 mcg to one-half the initial loading dose may be administered as needed.

General anesthetic:

50 to 100 mcg/kg (0.05 to 0.1 mg/kg) of body weight administered with oxygen and a muscle relaxant. Doses up to 150 mcg/kg (0.15 mg/kg) may be necessary. Used in open heart surgery and/or certain complicated neurologic or orthopedic procedures.

Postoperative pain management (recovery room):

50 to 100 mcg (0.05 to 0.1 mg) IM for control of pain, tachypnea, and emergence delirium. Repeat in 1 to 2 hours as needed.

Pain management as an IV injection (unlabeled):

An initial dose of 25 to 100 mcg (0.025 to 0.1 mg). Titrate to effect.

Pain management as an infusion (unlabeled):

Used postoperatively with a patient-controlled analgesic (PCA) device. One source suggests a concentration of 10 mcg/mL, with a starting patient-controlled dose of 10 to 20 mcg and a lockout interval of 4 to 10 minutes. See pain literature.

Pain management in critically ill patients (unlabeled):

Initiated as a continuous infusion at 25 to 50 mcg/hr. Titrate to desired effect. Doses up to 700 mcg/hr have been used. Several regimens are in use. See pain literature.

PEDIATRIC DOSE

Induction and maintenance in pediatric patients 2 to 12 years of age:

A reduced dose as low as 2 to 3 mcg/kg is recommended. See Maternal/Child.

Pain management (unlabeled):

0.5 to 2 mcg/kg/dose every 2 to 4 hours as needed. Titrate to effect.

DOSE ADJUSTMENTS

Reduce dose in patients receiving other CNS depressants, such as general anesthetics, alcohol, anticholinergics, antihistamines, barbiturates, hypnotics, sedatives, psychotropic agents, and narcotic analgesics. When concurrent administration is required, consider reducing the dose of one or both drugs. ■ Reduce dose or increase intervals for elderly, debilitated, and poor-risk patients or those with impaired pulmonary, hepatic, or renal function. ■ See Drug/Lab Interactions.

DILUTION

Small volumes may be given undiluted. May be given through Y-tube or three-way stopcock of infusion set. May be further diluted with NS and administered as an infusion or PCA (unlabeled).

Storage:

Store at room temperature and protect from light before dilution. Use promptly.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer over 1 to 2 minutes. Too-rapid administration may result in apnea or respiratory paralysis. Rate must be titrated by desired dose and patient response.

ACTIONS

A potent opioid agonist whose principal actions of therapeutic value are analgesia and sedation. Binds to receptors in the CNS, increasing the pain threshold and altering the perception of pain. Produces respiratory depression by direct action on brain stem respiratory centers. Produces peripheral vasodilation, which may result in orthostatic hypotension or syncope. Fentanyl is approximately 100 times more potent than morphine milligram for milligram (100 **mcg** of fentanyl is approximately equivalent to 10 **mg** of morphine). It has respiratory-depressant actions that may outlast its analgesic effect. Duration and degree of respiratory depression are dose related. Onset of action is almost immediate; however, the maximal analgesic and respiratory depressant effect may not be noted for several minutes. The usual duration of action of analgesic effect is 30 to 60 minutes after a single IV dose of up to 100 mcg. Effects are cumulative with repeat doses. Half-life is approximately 3.6 hours. Metabolized in the liver and excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

A narcotic analgesic supplement in general and regional anesthesia. ■ Short-term analgesia during perioperative period. ■ For administration with a neuroleptic such as droperidol as an anesthetic premedication, for the induction of anesthesia, and as an adjunct in the maintenance of general and regional anesthesia. ■ For use as an anesthetic agent with oxygen in selected high-risk patients, such as those undergoing open heart surgery or certain complicated neurologic or orthopedic procedures. ■ Useful in short-duration minor surgery in outpatients and in diagnostic procedures or treatments that require the patient to be awake or very lightly anesthetized (e.g., bronchoscopy, radiologic studies, burn dressings, cystoscopy).

Unlabeled use:

Treatment of severe pain. Has been administered as an intermittent injection, as an epidural injection or infusion, and as patient-controlled analgesia (PCA).

CONTRAINDICATIONS

Patients with known intolerance to fentanyl and other opioid agonists.

PRECAUTIONS

Fentanyl exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing fentanyl, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Should be administered only by persons specifically trained in the use of IV anesthetics and management of the respiratory effects of potent opioids. ■ Serious, life-threatening, or fatal respiratory depression may occur with the use of fentanyl. ■ Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), resuscitative and intubation equipment, and oxygen should be readily available. ■ The respiratory depressant effect of fentanyl may persist longer than the analgesic effect. The total dose of all opioid agonists administered should be considered before ordering opioid analgesics during recovery from anesthesia. ■ Use caution in patients with pulmonary disease or cor pulmonale and in those with decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea. ■ Sleep-related breathing disorders, including central sleep apnea (CSA) and sleep-related hypoxemia, can occur. Opioid use increases the risk of CSA in a dose-dependent fashion. ■ Use caution in cachectic or debilitated patients, in elderly patients, and in patients with impaired hepatic or renal function; these patients may be at an increased risk for adverse effects, including respiratory depression. Reduced dose may be indicated. ■ May cause muscle rigidity, particularly with muscles of respiration. Incidence and severity of muscle rigidity is rate- and dose-related. The incidence of muscle rigidity may be reduced by (1) administration of up to one-fourth of the full paralyzing dose of a nondepolarizing neuromuscular blocking agent just before administration of fentanyl, (2) administration of a full paralyzing dose of a neuromuscular blocking agent following loss of eyelash reflex when fentanyl is used in anesthetic doses titrated by slow IV infusion, or (3) simultaneous administration of fentanyl and a full paralyzing dose of a neuromuscular blocking agent when fentanyl is used in rapidly administered anesthetic doses. ■ In patients with circulatory shock, fentanyl may cause vasodilation, which can further reduce cardiac output and blood pressure. ■ Cases of serotonin syndrome have been reported during concomitant use of fentanyl with serotonergic drugs. ■ Cases of adrenal insufficiency have been reported with opioid use, more often following more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids, and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried; some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Use caution in patients with biliary tract disease, including acute pancreatitis. May cause spasm of the sphincter of Oddi. Opioids may cause increases in amylase. ■ Fentanyl may increase the frequency of seizures in patients with seizure disorders. ■ Use caution when administered with a neuroleptic agent (e.g., droperidol

[Inapsine]). Neuroleptics have been associated with QT prolongation, torsades de pointes, and cardiac arrest. Use extreme caution in patients at risk for prolonged QT syndrome, such as patients with clinically significant bradycardia (less than 50 bpm) or clinically significant cardiac disease (including baseline-prolonged QT interval), patients treated with Class I (e.g., disopyramide, quinidine) and Class III antiarrhythmics (e.g., amiodarone, ibutilide, sotalol), patients treated with MAO inhibitors, patients undergoing concomitant treatment with other agents known to prolong the QT interval, patients with electrolyte imbalance (particularly hypokalemia and hypomagnesemia), or patients treated with concomitant agents (e.g., diuretics) that may cause electrolyte imbalance. Cardiac dysrhythmias, cardiac arrest, and death have been reported. ■ May cause severe bradycardia, hypotension, and syncope. Use caution in patients with bradyarrhythmias. ■ See Drug/Lab Interactions.

Monitor:

Monitor for respiratory depression, especially during initiation of therapy or after a dose increase. Oxygen, controlled respiratory equipment, naloxone, and neuromuscular blocking agents (e.g., succinylcholine) must always be available. May cause rigidity of respiratory muscles; may require a muscle relaxant to permit artificial ventilation. ■ Observe patient frequently; monitor vital signs and oxygenation. Patient may appear to be asleep and may forget to breathe unless commanded to do so. ■ Monitor patient for breathing disorders (e.g., CSA and sleep-related hypoxemia), and consider decreasing the opioid dosage using best practices for opioid taper. ■ Keep patient supine; orthostatic hypotension and fainting may occur. ■ In patients with circulatory shock, monitor for signs of hypotension after initiating or titrating the dosage of fentanyl. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ ECG monitoring indicated when a neuroleptic drug is administered with fentanyl. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ See Precautions.

Patient Education:

Avoid use of alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines). ■ Promptly report S/S of serotonin syndrome. ■ Use caution performing any task requiring alertness; may cause dizziness, euphoria, and sedation. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended. ■ Blurred vision, dizziness, drowsiness, or light-headedness may occur; request assistance with ambulation. ■ Review all medications for interactions.

Maternal/Child:

Safety for use in pregnancy and labor and delivery not established. Fentanyl is not recommended for use in pregnant women during or immediately before labor when other analgesic techniques are more appropriate. ■ Prolonged use of opioid analgesics during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. ■ Use caution with breast-feeding. Monitor infants exposed to fentanyl through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety for use in pediatric patients under 2 years of age not established; rare cases of clinically significant methemoglobinemia have been reported in premature neonates; see Precautions.

Elderly:

See Dose Adjustments and Precautions. ■ May be more sensitive to effects (e.g., respiratory depression, urinary retention, constipation). Respiratory depression is the chief risk in elderly patients. ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment; may delay postoperative recovery.

DRUG/LAB INTERACTIONS

Concomitant use of fentanyl with **benzodiazepines** (e.g., diazepam, midazolam) and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required, and monitor patients carefully for S/S of respiratory depression and sedation. When such combinations are administered, IV fluids and other measures to manage hypotension should be available. ■ Use caution with concomitant use of fentanyl and **CYP3A4 inhibitors** (e.g., macrolide antibiotics, azole antifungals, and protease inhibitors) or when discontinuing a **CYP3A4 inducer** (e.g., rifampin, carbamazepine, phenytoin) in a fentanyl-treated patient. May increase plasma concentration of fentanyl and increase or prolong opioid adverse effects, and may cause potentially fatal respiratory depression. Dose reduction may be indicated. ■ Alternatively, concomitant use of fentanyl with CYP34A4 inducers or discontinuation of a CYP34A4 inhibitor could result in lower than expected fentanyl plasma concentration and decreased efficacy. An increase in the dose of fentanyl may be required. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including fentanyl, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT$_3$ receptor antagonists, mirtazapine, trazodone, tramadol, certain muscle relaxants [e.g., cyclobenzaprine, metaxalone], MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., selegiline, phenelzine, tranylcypromine, linezolid) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of fentanyl is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. ■ **Mixed agonist/antagonist analgesics and partial agonists** (e.g., buprenorphine, butorphanol, nalbuphine) may reduce the analgesic effect of fentanyl and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Fentanyl may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine, orphenadrine), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ Cardiovascular depression may result from concurrent use of **diazepam** or **nitrous oxide** and high-dose fentanyl. ■ Concurrent use with **neuroleptic agents** may cause elevated BP, with or without pre-existing hypertension.

SIDE EFFECTS

Apnea, bradycardia, respiratory depression, and respiratory muscle rigidity are the most common serious adverse reactions. Untreated, they may lead to respiratory arrest, circulatory depression, and cardiac arrest. Blurred vision, bronchoconstriction, diaphoresis, dizziness, hypersensitivity reactions (e.g., anaphylaxis, laryngospasm, pruritus, urticaria), hypertension, hypotension, nausea, respiratory depression (slight), and vomiting have been reported. Cases of adrenal insufficiency, androgen deficiency, and serotonin syndrome have been reported.

Overdose:

Atypical snoring; bradycardia; cold, clammy skin; death; hypotension; partial or complete airway obstruction; pinpoint pupils of eyes; pulmonary edema; respiratory depression; skeletal muscle flaccidity; somnolence progressing to stupor or coma. Marked mydriasis rather than miosis may be seen with hypoxia in overdose situations.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone will reverse serious respiratory depression. Because the duration of opioid reversal is expected to be less than the duration of action of fentanyl, careful monitoring is necessary and repeat doses of naloxone may be required. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat hypotension with a Trendelenburg position and IV fluids or vasopressors (e.g., dopamine, norepinephrine) as needed. Avoid epinephrine if a neuroleptic agent has also been administered. May paradoxically decrease BP when given with neuroleptics that block alpha-adrenergic activity. A fast-acting muscle relaxant (e.g., succinylcholine) may be required to facilitate ventilation. Use atropine to treat bradycardia. Muscle rigidity during anesthesia induction or surgery must be controlled with neuromuscular blocking agents and controlled ventilation with oxygen. Use a neuromuscular blocking agent prophylactically to prevent muscle rigidity or to induce muscle relaxation after rigidity occurs. Resuscitate as necessary.

FERRIC CARBOXYMALTOSE INJECTION

(**FER**-ik kar-box-ee **MAWL**-tose)
Injectafer
Hematinic
Iron supplement
Antianemic
pH 5 to 7

USUAL DOSE

Dose is expressed in terms of mg of elemental iron. Each course consists of 2 doses given at least 7 days apart. Treatment may be repeated if iron deficiency recurs.

Patients weighing 50 kg or more:

Give in 2 doses separated by at least 7 days. Give each dose as 750 mg for a total cumulative dose not to exceed 1,500 mg of iron per course.

Patients weighing less than 50 kg:

Give in 2 doses separated by at least 7 days. Give each dose as 15 mg/kg body weight for a total cumulative dose not to exceed 1,500 mg of iron per course.

DILUTION

Available in a 750 mg/15 mL (50 mg/mL) single-use vial. May be given undiluted as a slow intravenous push or further diluted in NS and given as an infusion. When administering as an infusion, dilute dose in no more than 250 mL of NS. Do not dilute to concentrations below 2 mg/mL.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Do not freeze. Solutions diluted with NS to a concentration of 2 to 4 mg/mL are stable for 72 hours at RT. Vials are single use. Discard any unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Slow IV push:

A single undiluted dose at a rate of 100 mg/min (7.5 minutes for a 750-mg dose).

Infusion:

Administer over at least 15 minutes.

ACTIONS

A colloidal iron (III) hydroxide in complex with carboxymaltose, a carbohydrate polymer that releases iron. Used to replenish the total body iron stores in patients with iron deficiency. Iron is critical for normal hemoglobin synthesis to maintain oxygen transport and necessary for metabolism and synthesis of DNA and various other processes. Rapidly cleared from the plasma following administration. Iron distributes into liver, spleen, and bone marrow. Because the disappearance of iron from serum depends on the need for iron in the iron stores and iron-utilizing tissues of the body, serum clearance of iron is expected to be more rapid in patients with iron deficiency as compared with healthy individuals. Terminal half-life is 7 to 12 hours. Renal elimination of iron is negligible. Excreted in breast milk.

INDICATIONS AND USES

Treatment of iron deficiency anemia in adult patients who have intolerance to oral iron or have had an unsatisfactory response to oral iron and in adult patients who have non–dialysis dependent chronic kidney disease.

CONTRAINDICATIONS

Known hypersensitivity to ferric carboxymaltose or any of its components.

PRECAUTIONS

Serious hypersensitivity reactions, including anaphylactic-type reactions, some of which have been life-threatening and fatal, have been reported. Patients may present with shock, clinically significant hypotension, loss of consciousness, and/or collapse. Other serious reactions potentially associated with hypersensitivity have included pruritus, rash, urticaria, and wheezing. ■ Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Transient elevations in systolic blood pressure, sometimes occurring with dizziness, facial flushing, or nausea, have been reported. ■ Avoid extravasation. Brown discoloration of extravasation site may be long lasting.

Monitor:

Confirm IV placement. If extravasation occurs, discontinue administration at that site. ■ Monitor for S/S of hypersensitivity reactions (e.g., acute respiratory distress, angioedema, chest tightness, hypotension, lethargy, nausea, paresthesia, pruritus, restlessness, urticaria, vomiting, wheezing) during and after administration for at least 30 minutes and until clinically stable; see Precautions. ■ Monitor vital signs and monitor for S/S of hypertension following administration. ■ Periodic monitoring of hematologic and hematinic parameters (hemoglobin, hematocrit, serum ferritin, and transferrin saturation) is indicated during parenteral iron replacement therapy; see Drug/Lab Interactions.

Patient Education:

Review any possible reactions to past parenteral iron therapy. ■ Report S/S of a hypersensitivity reaction promptly (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing).

Maternal/Child:

Use in pregnancy only if clearly needed and if potential benefit justifies the potential risk to the fetus. Untreated iron deficiency anemia (IDA) in pregnancy is associated with adverse maternal outcomes such as postpartum anemia. Adverse pregnancy outcomes associated with IDA include increased risk for preterm delivery and low birth weight. ■ Iron is present in breast milk. There is no information on the effects of use on milk production. Consider developmental and health benefits of breast-feeding along with the mother's clinical need for ferric carboxymaltose. Monitor breast-fed infants for gastrointestinal toxicity (constipation, diarrhea). ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Differences in response between elderly and younger patients have not been identified, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Specific information not available. ■ In the 24 hours following administration of ferric carboxymaltose, laboratory assays may overestimate serum iron and transferrin-bound iron by also measuring the iron in ferric carboxymaltose.

SIDE EFFECTS

The most common side effects are dizziness, flushing, hypertension, hypophosphatemia, and nausea. Less frequently reported side effects include abdominal pain, constipation, diarrhea, dysgeusia, elevated ALT and gamma glutamyl transferase, headache, hypersensitivity reactions, hypertension, hypotension, injection site discoloration and pain/irritation, paresthesia, rash, sneezing, and vomiting.

Overdose:

Hemosiderosis.

Post-Marketing:

Angioedema, arthralgia, back pain, chest discomfort, chills, dyspnea, erythema, fever, pruritus, syncope, tachycardia, urticaria.

ANTIDOTE

Keep physician informed of all side effects. Discontinue drug if severe hypersensitivity reactions occur. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Treat hypertension as indicated. Resuscitate as needed.

FERUMOXYTOL BBW

(**FER**-ue-**MOX**-i-tol)
Feraheme
Antianemic
Iron supplement
pH 6 to 8

USUAL DOSE

An initial IV dose of 510 mg followed by a second IV dose of 510 mg 3 to 8 days later. Administer as an IV infusion over at least 15 minutes. After 1 month and an evaluation of the hematologic response, the recommended dose may be repeated in patients with persistent or recurrent iron deficiency anemia. Administer to hemodialysis patients at least 1 hour into dialysis session, after blood pressure has stabilized. Patient should receive infusion in a reclined or semi-reclined position; see Monitor. See Drug/Lab Interactions.

DOSE ADJUSTMENTS

No dose adjustment is required and no gender differences have been observed.

DILUTION

Available in a single-use vial containing 510 mg of elemental iron in 17 mL (30 mg/mL of elemental iron). Black to reddish brown in color. This single dose must be further diluted in 50 to 200 mL of NS or D5W for administration as an IV infusion.

Filters:

Specific information not available.

Storage:

Store unopened vials at CRT. When added to D5W or NS at concentrations of 2 to 8 mg of elemental iron/mL, may be stored at RT for up to 4 hours or refrigerated for up to 48 hours. However, immediate use is preferred. Discard unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. Given as an IV infusion. Consider flushing the IV line with NS before and after infusion.

RATE OF ADMINISTRATION

Administer as an IV infusion over at least 15 minutes.

ACTIONS

An iron-replacement product. A superparamagnetic iron oxide that is coated with a carbohydrate shell. The shell helps to isolate the bioactive iron from plasma components until the iron-carbohydrate complex enters the reticuloendothelial system macrophages of the liver, spleen, and bone marrow. The iron is released from the complex within the macrophages and then either enters the intracellular storage iron pool (e.g., ferritin) or is transferred to plasma transferrin for transport to erythroid precursor cells for incorporation into hemoglobin. Exhibits dose-dependent, capacity-limited elimination from plasma with a half-life of approximately 15 hours.

INDICATIONS AND USES

Treatment of iron deficiency anemia (IDA) in adult patients who have intolerance to oral iron or have had unsatisfactory response to oral iron or who have chronic kidney disease (CKD).

CONTRAINDICATIONS

Known hypersensitivity to ferumoxytol or any of its components. ■ History of allergic reaction to any intravenous iron product. ■ Should not be used in patients with evidence of iron overload or in patients with anemia not caused by iron deficiency.

PRECAUTIONS

Fatal and serious hypersensitivity reactions, including anaphylaxis, have been reported. Reactions have occurred after the first dose or subsequent doses of ferumoxytol in patients in whom a previous dose was tolerated. Patients with a history of multiple drug allergies may have a greater risk of anaphylaxis. Consider risk versus benefit of administration. ■ Facilities for monitoring the patient and responding to any medical emergency must be available. ■ Use only when truly indicated. Excessive therapy with parenteral iron can lead to excess storage of iron with the possibility of iatrogenic hemosiderosis. One source recommends discontinuing oral iron before administering parenteral iron. ■ Clinically significant hypotension has been reported. ■ May transiently affect the diagnostic ability of MRI studies. Anticipated MRI studies should be conducted before administration of ferumoxytol. Alteration of MRI studies may last for up to 3 months after the last ferumoxytol dose. See manufacturer’s prescribing information if MRI studies must be obtained after ferumoxytol administration. Ferumoxytol does not interfere with x-ray, computed tomography (CT), positron emission tomography (PET), single photon emission computed tomography (SPECT), ultrasound, or nuclear medicine imaging.

Monitor:

Patient should be in a reclined or semi-reclined position during and after administration to prevent postural hypotension. ■ BP should be stable in patients receiving hemodialysis before dose is administered. ■ Monitor BP and HR during and after dose administration. ■ Observe for hypersensitivity reactions (e.g., anaphylaxis, cardiac or cardiopulmonary arrest, clinically significant hypotension, pruritus, rash, syncope, unresponsiveness, urticaria, or wheezing) during and for at least 30 minutes and until clinically stable after administration. ■ Evaluate hematologic response (hemoglobin, hematocrit, ferritin, iron, and transferrin saturation) at least 1 month after the second dose. Regularly monitor response during parenteral iron therapy. Avoid evaluation of therapy immediately after therapy. In the 24 hours following administration, laboratory assays may overestimate serum iron and transferrin-bound iron by also measuring the iron in the ferumoxytol complex.

Patient Education:

Review FDA-approved patient package insert. ■ Review any possible reactions to past parenteral iron therapy. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, itching, rash, shortness of breath, wheezing).

Maternal/Child:

Use during pregnancy only if potential benefit to the mother justifies the potential risk to the fetus. There are risks to the mother and fetus associated with untreated iron deficiency anemia. Adverse outcomes may include maternal postpartum anemia, preterm delivery, and low birth weight. ■ There are no data on the presence of ferumoxytol in human milk, the effects on the breast-fed infant, or the effects on milk production. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety and efficacy were observed between older and younger patients. However, greater sensitivity of older patients cannot be ruled out. Elderly patients with multiple or serious comorbidities who experience hypersensitivity reactions and/or hypotension after administration of ferumoxytol may have more severe outcomes. Consider risk versus benefit of administration.

DRUG/LAB INTERACTIONS

Drug-drug interaction studies have not been conducted. ■ May reduce the absorption of concomitantly administered **oral iron** preparations. ■ Allow at least 30 minutes between administration of ferumoxytol and administration of other medications that could potentially cause serious hypersensitivity reactions and/or hypotension (e.g., chemotherapeutic agents or monoclonal antibodies).

SIDE EFFECTS

The most common side effects are constipation, diarrhea, dizziness, headache, hypotension, nausea, and peripheral edema. Serious side effects may include hypersensitivity reactions (e.g., anaphylaxis, pruritus, rash, urticaria, or wheezing) and hypotension. Other reported side effects are abdominal pain, back pain, chest pain, cough, dyspnea, ecchymosis, edema, fatigue, fever, infusion site swelling, muscle spasm, vomiting.

Post-Marketing:

Anaphylactic/anaphylactoid reactions (fatal, life-threatening, or serious), angioedema, cardiac/cardiopulmonary arrest, CHF, cyanosis, hypotension (clinically significant), ischemic myocardial events, loss of consciousness, syncope, tachycardia/rhythm abnormalities, and unresponsiveness.

ANTIDOTE

Notify the physician of significant side effects. Treat hypersensitivity reactions, or resuscitate as necessary. Epinephrine and diphenhydramine should always be available.

In overdose, monitor CBC, iron studies, vital signs, blood gases, glucose, and electrolytes. Maintain fluid and electrolyte balance. Consultation with a poison control center may be warranted. Deferoxamine is an iron chelating agent and may be useful in iron toxicity or overdose. Dialysis will not remove iron alone but will remove the iron deferoxamine complex and is indicated if oliguria or anuria is present.

FIBRINOGEN CONCENTRATE (HUMAN)

Coagulation factor I

USUAL DOSE

Individualize dosing, duration of dosing, and frequency of administration based on the extent of bleeding, laboratory values, and clinical condition. A target fibrinogen level of 100 mg/dL should be maintained until hemostasis is obtained.

Dose when baseline fibrinogen level IS known:

Calculate individually for each patient based on the target plasma fibrinogen level, which is based on the type of bleeding, actual measured plasma fibrinogen level, and body weight using the following formula:

$$\text{Dose (mg/kg)} = \frac{\text{(Target level [mg/dL]–Measured level [mg/dL])}}{\text{1.7 (mg/dL per mg/kg body weight)}}$$

Dose when baseline fibrinogen level IS NOT known:

70 mg/kg.

DILUTION

Available as a single-use vial containing 900 to 1,300 mg lyophilized fibrinogen concentrate powder. Fibrinogen potency for each lot is printed on the vial label and carton. Bring fibrinogen concentrate to room temperature. Reconstitute with 50 mL SWFI. Gently swirl until the powder is completely dissolved. Solution should be colorless and may be clear or slightly opalescent. Do not shake. Administer within 24 hours of reconstitution.

Filters:

Specific information not available.

Storage:

Store in carton between 2° and 25° C (36° and 77° F). Protect from light. Do not freeze in powder or reconstituted form. Do not use beyond expiration date on vial. Reconstituted solution is stable for 24 hours at CRT. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with other medicinal products or intravenous solutions, and should be administered through a separate injection site.”

RATE OF ADMINISTRATION

A single dose is to be given at a rate not to exceed 5 mL/min.

ACTIONS

Fibrinogen (factor I) is a soluble plasma glycoprotein made from cryoprecipitate derived from pooled human plasma. It is a physiologic substrate of three enzymes—thrombin, factor XIIIa, and plasmin—and is an essential part of the coagulation cascade required for forming blood clots and preventing bleeding. In patients with congenital fibrinogen deficiency, it replaces the missing or low coagulation factor (normal levels range from 200 to 400 mg/dL). Less than 100 mg/dL can be associated with spontaneous bleeding; without treatment, these patients are at risk for potentially life-threatening bleeding. Half-life is 78.7 ± 18.13 hours (range 55.73 to 117.26 hours).

INDICATIONS AND USES

Treatment of acute bleeding episodes in patients with congenital fibrinogen deficiency, including afibrinogenemia and hypofibrinogenemia. ■ Not indicated for use in dysfibrinogenemia (malfunction of fibrinogen in the blood).

CONTRAINDICATIONS

Known hypersensitivity to fibrinogen concentrate or its components.

PRECAUTIONS

For IV use only. ■ Administration under the supervision of a physician is recommended. ■ Severe hypersensitivity reactions, including anaphylaxis, may occur. Administer in a facility capable of monitoring the patient and responding to any medical emergency. Epinephrine should be immediately available. ■ Thrombotic events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis) have occurred in patients with congenital fibrinogen deficiency with or without the use of fibrinogen concentrate therapy. Consider benefit versus risk. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection.

Monitor:

Monitor fibrinogen levels during treatment. A target fibrinogen level of 100 mg/dL should be maintained until hemostasis is obtained. ■ Observe for symptoms of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor patients for S/S of thrombotic events.

Patient Education:

Inform patient of risks for infectious agent transmission and of safety precautions taken during the manufacturing process. ■ Promptly report symptoms of a hypersensitivity reaction (e.g., difficulty breathing, feeling faint, hives, itching, tightness in the chest, wheezing). ■ Promptly report symptoms of a possible thrombosis (e.g., altered consciousness or speech; loss of sensation or motor power; new-onset swelling and pain in abdomen, chest, or limbs; shortness of breath).

Maternal/Child:

Category C: safety and effectiveness for use during pregnancy, labor and delivery, and breast-feeding not studied; use only if clearly needed. ■ Clinical studies included 5 patients between 8 and 16 years of age; a shorter half-life and faster clearance were noted in these patients.

Elderly:

Numbers in clinical studies are insufficient to determine whether the elderly respond differently than younger subjects.

DRUG/LAB INTERACTIONS

No drug interaction studies have been conducted.

SIDE EFFECTS

The most common side effects reported include chills, fever, headache, hypersensitivity reactions, nausea, and vomiting. The most serious side effects include hypersensitivity reactions (e.g., anaphylaxis, dyspnea, hives, hypotension, rash, tightness of the chest, urticaria, and wheezing) and thrombotic events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis).

ANTIDOTE

Keep the physician informed of all side effects. Interrupt or discontinue injection, if indicated, until symptoms subside; then resume at a tolerated rate. ■ Discontinue fibrinogen concentrate if anaphylaxis or thrombotic events occur. Treat thrombotic events as indicated. Treat anaphylaxis with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

FILGRASTIM ■ FILGRASTIM-aafi[a] ■ FILGRASTIM-sndz[a]

(fill-**GRASS**-tim)

G-CSF, Human Granulocyte Colony-Stimulating Factor, Neupogen ■ Nivestym[a] ■ Releuko[a] ■ Zarxio[a]

Colony-stimulating factor

Hematopoietic agent

pH 4

USUAL DOSE

Filgrastim-aafi[a] (Nivestym) and Filgrastim-sndz (Zarxio)[a] and filgrastim -ayow (Releuko) are biosimilar drugs of filgrastim (Neupogen). Unless specifically stated otherwise, monograph information and the use of the name *filgrastim or filgrastim product(s)* applies to all formulations.

Filgrastim products:

Do not use 24 hours before to 24 hours after the administration of cytotoxic chemotherapy because of the potential sensitivity of rapidly dividing myeloid cells to cytotoxic chemotherapy. Safety and effectiveness for use with concurrent radiation therapy have not been evaluated; simultaneous use should be avoided.

Pretreatment:

Baseline studies indicated and diagnosis confirmation may be indicated; see Monitor.

Cancer patients receiving myelosuppressive chemotherapy or induction and/or consolidation chemotherapy for acute myeloid leukemia (AML):

The recommended starting dose is 5 mcg/kg/24 hr administered as a single daily injection by subcutaneous injection, short intravenous infusion, or continuous intravenous infusion. Administer daily for up to 2 weeks or until the ANC has reached 10,000/mm^3 following the expected chemotherapy-induced neutrophil nadir. Duration of therapy needed may be dependent on the myelosuppressive potential of the chemotherapy regimen employed. Expect a transient increase in neutrophil counts 1 to 2 days after initiation of therapy. In clinical trials, efficacy was observed at doses of 4 to 8 mcg/kg/day. See Monitor.

Bone marrow transplant (BMT):

10 mcg/kg/24 hr as an IV infusion over no longer than 24 hours. Give the first dose at least 24 hours after cytotoxic chemotherapy and 24 hours after bone marrow infusion.

Nivestym and Zarxio:

Direct administration of less than 0.3 mL (180 mcg) is not recommended due to the potential for dosing errors. The spring mechanism of the BD UltraSafe Passive™ Needle Guard apparatus interferes with the visibility of the graduated markings corresponding to 0.1 mL and 0.2 mL.

DOSE ADJUSTMENTS

Consider dose escalation in increments of 5 mcg/kg for each chemotherapy cycle, according to the duration and severity of the ANC nadir. Discontinue filgrastim if the ANC surpasses 10,000/mm^3 after the chemotherapy-induced ANC nadir has occurred.
■ During neutrophil recovery after BMT, titrate the daily dose against the neutrophil response as shown in the following chart.

Filgrastim Dose Adjustments During Neutrophil Recovery Following a Bone Marrow Transplant (BMT)	
Absolute Neutrophil Count (ANC)	**Filgrastim Dose**
When ANC >1,000/mm^3 for 3 consecutive days	Reduce to 5 mcg/kg/day[a]
Then: If ANC remains >1,000/mm^3 for 3 more consecutive days	Discontinue filgrastim[a]
Then: If ANC decreases to <1,000/mm^3	Resume at 5 mcg/kg/day

[a] If ANC decreases to less than 1,000/mm^3 at any time during the 5 mcg/kg/day administration, increase filgrastim to 10 mcg/kg/day; the above steps should then be followed.

- Consider dose reduction and/or interruption of therapy in patients who develop glomerulonephritis or cutaneous vasculitis thought to be related to filgrastim therapy; see Antidote.

DILUTION

Neupogen and Nivestym:

Available as a single-dose vial with either 300 mcg/mL or 480 mcg/1.6 mL and as a prefilled syringe with an UltraSafe Needle Guard® as 300 mcg/0.5 mL or 480 mcg/0.8 mL.

Zarxio:

Available as a prefilled syringe with an UltraSafe Passive™ Needle Guard as 300 mcg/0.5 mL or 480 mcg/0.8mL.

Filgrastim products:

Remove from refrigerator to allow to warm to room temperature for a minimum of 30 minutes and a maximum of 24 hours.

Neupogen and Nivestym (vials):

Confirm expiration date to ensure valid product. Avoid shaking. Contains no preservatives; use sterile technique, entering vial only once to withdraw a single dose. May dilute with D5W to concentrations of 5 to 300 mcg/mL. With concentrations from 5 to 15 mcg/mL, filgrastim must be combined with albumin to a final concentration of 2 mg/mL to prevent adsorption to plastic (e.g., add 2 mL of 5% albumin to each 50 mL of D5W). Discard any unused portion. Should be clear and colorless. Do not dilute to less than 5 mcg/mL.

Filgrastim products in prefilled syringes:

Primarily used for SC administration; however, **Zarxio** syringes may be diluted for IV use in D5W to concentrations between 5 and 15 mcg/mL. With concentrations from 5 to 15 mcg/mL, Zarxio also must be combined with albumin to a final concentration of 2 mg/mL to prevent adsorption to plastic (e.g., add 2 mL of 5% albumin to each 50 mL of D5W). Do not dilute to less than 5 mcg/mL.

Storage:

Before use, store filgrastim in refrigerator in original packaging to protect from light. Avoid freezing; if frozen, thaw in the refrigerator before administration. Discard if frozen more than once. Do not expose to direct sunlight. Avoid shaking. Discard any vial, diluted solution, or prefilled syringe left at RT for more than 24 hours, including administration time.

COMPATIBILITY

Filgrastim products:

Manufacturers state, ***"Do not dilute with saline at any time; product may precipitate."*** Incompatible with saline.

Other sources suggest specific compatibilities for **Neupogen** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent infusion:

A single dose over 15 to 30 minutes.

Continuous infusion:

A single dose over no more than 24 hours. In all situations, flush IV line with D5W before and after administration.

ACTIONS

A human granulocyte colony-stimulating factor (G-CSF) manufactured by recombinant DNA technology. Colony-stimulating factors are glycoproteins that bind to specific hematopoietic cell surface receptors and stimulate proliferation, differentiation commitment, and some end-cell functional activation. Endogenous granulocyte colony-stimulating factor is produced by monocytes, fibroblasts, and endothelial cells. G-CSF is lineage-specific with selectivity for the neutrophil lineage. It regulates the production of neutrophils within the bone marrow and affects neutrophil progenitor proliferation, differentiation, and selected end-cell functions. In studies, administration of filgrastim products resulted in a dose-dependent increase in circulating neutrophil counts. Absolute monocyte counts also increased in a dose-dependent manner; however, the percentage of monocytes in the differential count remained within the normal range. With discontinuation of therapy, neutrophil counts returned to baseline in most cases within 4 days. The elimination half-life is approximately 3.5 hours. Filgrastim and filgrastim-sndz have been shown to be safe and effective in accelerating the recovery of neutrophil counts following a variety of chemotherapy regimens. In studies, benefits to therapy were shown to be prevention of infection as manifested by febrile neutropenia, decreased hospitalization, and decreased IV antibiotic usage. The incidence, severity, and duration of severe neutropenia (absolute neutrophil count [ANC] less than $500/mm^3$) following chemotherapy were all significantly reduced.

INDICATIONS AND USES

Decrease the incidence of infection (febrile neutropenia) in patients with nonmyeloid malignancies receiving myelosuppressive anticancer drugs associated with a significant incidence of severe neutropenia with fever. ■ Reduce the time to neutrophil recovery and the duration of fever, following induction or consolidation chemotherapy treatment of adults with AML. ■ Decrease duration of neutropenia and related clinical problems (e.g., febrile neutropenia) in patients with nonmyeloid malignancies receiving myeloablative chemotherapy followed by BMT. ■ Used SC to treat severe chronic neutropenia (e.g., congenital, cyclic, or idiopathic) after all diseases associated with neutropenia have been ruled out. Administered chronically to reduce the incidence and duration of sequelae of neutropenia (e.g., fever, infections, oropharyngeal ulcers) in symptomatic patients. ■ Used SC to mobilize autologous hematopoietic progenitor cells into the peripheral blood for collection by leukapheresis with transplantation after myeloablative chemotherapy.

Neupogen:

Used SC to increase survival in patients acutely exposed to myelosuppressive doses of radiation. (Efficacy studies could not be conducted in humans with acute radiation syndrome for ethical and feasibility reasons. Approval of this indication was based on efficacy studies conducted in animals and on data supporting the use of filgrastim for other approved indications.)

CONTRAINDICATIONS

Serious hypersensitivity reaction to human granulocyte colony-stimulating factors such as filgrastim or pegfilgrastim.

PRECAUTIONS

Should be administered under the direction of a physician knowledgeable about appropriate use for each indication (e.g., expert in bone marrow transplantation). ■ Frequently given by SC injection. ■ Use extreme caution in any malignancy with myeloid characteristics. The possibility that filgrastim can act as a growth factor for any tumor type, particularly myeloid malignancies, cannot be excluded. Safety in chronic myeloid leukemia (CML) and myelodysplasia has not been established. ■ When filgrastim is used to mobilize peripheral blood progenitor cells (PBPCs), tumor cells may be released from the marrow and subsequently collected in the leukapheresis product. The effect of reinfusion of tumor cells has not been well studied. Data are inconclusive. ■ Acute respiratory distress syndrome (ARDS) has been reported. ■ Hypersensitivity reactions have been reported. Majority have occurred with initial exposure. Allergic reactions, including anaphylaxis, can recur within days after the discontinuation of initial antiallergic treatment; see Monitor. ■ Splenic rupture has been reported; fatalities have occurred. ■ Glomerulonephritis has occurred in patients receiving filgrastim. ■ Severe sickle cell crises have been reported with the use of filgrastim in patients with sickle cell trait or sickle cell disease. Fatalities have occurred. Consider risk versus benefit. ■ Capillary leak syndrome (CLS) has been reported. Episodes vary in frequency and severity and may be life threatening if treatment is delayed. ■ Use caution in patients with congenital severe chronic neutropenia (SCN); risk of developing cytogenetic abnormalities, myelodysplastic syndromes (MDS), and acute myelogenous leukemia (AML) may be increased. If a patient with SCN develops abnormal cytogenetics or myelodysplasia, the risk versus benefit of continuing filgrastim therapy should be considered. ■ Alveolar hemorrhage manifesting as pulmonary infiltrates and hemoptysis and requiring hospitalization has been reported in healthy donors undergoing peripheral blood progenitor cell (PBPC) mobilization. Hemoptysis resolved when filgrastim was discontinued. Use of filgrastim for PBPC mobilization in healthy donors is not an approved indication. ■ Moderate to severe cutaneous vasculitis has been reported in patients treated with filgrastim. Most reports involved patients with SCN receiving long-term filgrastim therapy. ■ As with any therapeutic protein, potential for immunogenicity exists. ■ Thrombocytopenia has been reported; see Monitor. ■ Removable needle cap of Zarxio prefilled syringes contains latex. Safe use in latex-sensitive individuals has not been studied. Nivestym needle caps are not made with natural rubber latex.

Monitor:

Obtain a CBC and platelet count before chemotherapy begins and twice weekly thereafter to monitor the neutrophil count and to avoid leukocytosis. ■ Increase frequency of monitoring of CBC and platelet count after bone marrow infusion. ■ Because higher doses of chemotherapy may be tolerated, side effects associated with the chemotherapeutic drug may be more pronounced; observe carefully. ■ Observe for S/S of hypersensitivity reactions (e.g., hypotension, rash, tightness of the chest, urticaria, wheezing). ■ Evaluate patients complaining of left upper abdominal pain and/or shoulder pain for an enlarged spleen or splenic rupture. ■ Monitor respiratory status. Evaluate for ARDS if fever, lung infiltrates, or respiratory distress develop. ■ Monitor for S/S of CLS (e.g., edema, hypoalbuminemia, hypotension, and hemoconcentration). ■ Monitor for glomerulonephritis. Has been diagnosed based on the development of azotemia, hematuria, and proteinuria and with renal biopsy. ■ See Precautions.

Patient Education:

Promptly report any symptoms of infection (e.g., fever), abdominal or left shoulder pain, bruising, hypersensitivity reaction (itching, redness, swelling at the injection site) or dyspnea, with or without fever. ■ Promptly report symptoms of glomerulonephritis (e.g., swelling of face or ankles, dark-colored urine or blood in the urine, decrease in urine production) or cutaneous vasculitis (e.g., purpura, erythema). ■ Promptly report symptoms of cutaneous vasculitis (e.g., erythema, purpura) or aortitis (abdominal pain, back pain, fever, malaise). ■ May be self-injected SC by the patient at home; requires instruction. Literature includes a patient handout.

Maternal/Child:

An association with filgrastim use during pregnancy and major birth defects, miscarriage, or adverse maternal or fetal outcomes has not been seen in observational studies. ■ Secreted in breast milk but not orally absorbed by the neonate. Consider risks versus benefits. ■ Safety and effectiveness for use in pediatric patients with severe chronic neutropenia (SCN) have been established. Experience in pediatric patients similar to adult population in patients with cancer. May cause bone pain, fever, or rash. ■ The relationship is unclear; however, pediatric patients with congenital neutropenia have developed cytogenetic abnormalities and have undergone transformation to MDS and AML while receiving chronic filgrastim therapy.

Elderly:

Age-related differences in safety and efficacy have not been observed.

DRUG/LAB INTERACTIONS

Filgrastim products:

Interaction with other drugs has not been evaluated. ■ Increased hematopoietic activity of the bone marrow in response to growth factor therapy has been associated with transient positive bone-imaging changes. Consider when interpreting **bone-imaging results.** ■ Increases in **LDH, serum alkaline phosphatase, and serum uric acid** have been seen.

SIDE EFFECTS

Cancer patients receiving myelosuppressive chemotherapy:

Most common adverse reactions were cough, dyspnea, fever, pain, and rash.

Patients with acute myeloid leukemia (AML) receiving induction or consolidation chemotherapy:

Most common adverse reactions were epistaxis, pain, and rash. Bone marrow transplant (BMT): Most common adverse reaction was rash.

Other reported reactions included arthralgia, back pain, bone pain, chest pain, dizziness, fatigue, headache, increased alkaline phosphatase and lactate dehydrogenase, nausea, pain in an extremity, and thrombocytopenia. Hypersensitivity reactions (itching, redness, swelling at the injection site) have occurred; anaphylaxis is possible. Complaints of dose-related bone pain are common and may require analgesics. Serious side effects include acute respiratory distress syndrome (ARDS), alveolar hemorrhage and hemoptysis, capillary leak syndrome, cutaneous vasculitis, glomerulonephritis, leukocytosis, sickle cell disorders, splenic rupture, and thrombocytopenia.

Post-Marketing:

Acute respiratory distress syndrome (ARDS), alveolar hemorrhage and hemoptysis, anaphylaxis, aortitis, capillary leak syndrome, cutaneous vasculitis, glomerulonephritis, leukocytosis, splenic rupture, splenomegaly, Sweet’s syndrome (acute febrile neutrophilic dermatosis), and thrombocytopenia. Decreased bone density and osteoporosis have been reported in pediatric patients with severe chronic neutropenia (SCN) receiving chronic therapy.

ANTIDOTE

Notify physician promptly if any signs of infection (fever) or other potential side effects occur. Monitor potential leukocytosis with twice-weekly CBCs. Discontinue therapy after ANC surpasses 10,000/mm^3 and the chemotherapy nadir has occurred. Discontinue filgrastim and notify physician immediately if a generalized hypersensitivity reaction should occur. Treat hypersensitivity reactions as indicated. Withhold or discontinue for other side effects (e.g., ARDS, hemoptysis). Patients who experience CLS should receive standard symptomatic treatment, which may include the need for intensive care. Hold filgrastim therapy in patients with cutaneous vasculitis. May restart at reduced dose when symptoms resolve and ANC has decreased. Consider dose reduction and/or interruption of therapy in patients who develop glomerulonephritis. Discontinue filgrastim if leukocyte count rises to greater than 100,000/mm^3 during administration of filgrastim for PBPC mobilization or if aortitis is suspected.

FISH OIL TRIGLYCERIDES INJECTABLE EMULSION

(fish oyl tri-glyc-er-ides in-**JEK**-tuh-buhl e-**MUL**-shun)
Omegaven
Nutritional supplement
(fatty acid)
pH 6 to 9

PEDIATRIC DOSE

Pretreatment:

Baseline studies indicated; see Monitor. Correct severe water and electrolyte disorders before administration.

Dose depends on energy requirements, which may be influenced by patient's clinical status, body weight, tolerance, and ability to metabolize and eliminate lipids. The energy supplied by dextrose and amino acids from parenteral nutrition (PN), oral or enteral nutrition, and lipid-based medications must also be taken into account. May be administered alone or as part of a PN admixture. May be infused through a peripheral or central line; see Precautions.

Fish oil triglycerides:

1 Gm/kg/day is the recommended and maximum daily dose. Initiate as soon as direct bilirubin (DBil) or conjugated bilirubin levels are 2 mg/dL or greater in pediatric patients who are expected to be PN-dependent for at least 2 weeks. Administer until DBil levels are less than 2 mg/dL or until the patient no longer requires PN.

DOSE ADJUSTMENTS

If hypertriglyceridemia (triglycerides greater than 250 mg/dL in neonates and infants or greater than 400 mg/dL in older pediatric patients) develops once fish oil triglycerides has been initiated at the recommended dose, consider stopping the administration for 4 hours and then obtain a repeat serum triglyceride level. Resume fish oil triglycerides based on new result as indicated. ■ In patients with elevated triglyceride levels, consider other reasons for hypertriglyceridemia (e.g., renal disease, other drugs). If triglycerides remain at elevated levels, consider a reduced dose of 0.5 to 0.75 Gm/kg/day with an incremental increase to 1 Gm/kg/day.

DILUTION

Fish oil triglycerides (Omegaven) is a white, homogenous, sterile emulsion supplied in 5 Gm/50 mL and 10 Gm/100 mL single-dose glass bottles.

Fish oil triglycerides as a single agent:

Before infusion, visually inspect for particulate matter and discoloration; discard if observed. Gently invert the bottle before use. Emulsion should be homogeneous and the container undamaged. Do not use if there appears to be an oiling out of the emulsion. See Rate of Administration for tubing, filter, and connection requirements and specific procedures. Hang the bottle using the attached hanger and start infusion.

Fish oil triglycerides as a component of parenteral nutrition (PN):

Follow manufacturer's specific instructions for preparation when used in combination with dextrose and amino acids. See Rate of Administration.

Filters:

Use of a 1.2-micron in-line filter required.

Storage:

Store below 25° C (77° F). Avoid excessive heat. Do not freeze. If accidentally frozen, discard product. Once connected to infusion set, use immediately and complete within 12 hours when using a Y-connector and within 24 hours when used as part of an admixture. Admixtures should be used immediately but may be stored for up to 6 hours at RT or up to 24 hours under refrigeration. Complete infusion within 24 hours after removal from storage. For single use only; discard any unused portion.

COMPATIBILITY

Manufacturer states, "Do not use infusion sets and lines that contain di-2-ethylhexyl phthalate (DEHP). Infusion sets that contain polyvinyl chloride (PVC) components have DEHP as a plasticizer." Lipids may extract phthalates from phthalate-plasticized PVC infusion sets and lines. Emulsions are destabilized by excessive acidity (such as a pH less than 5) and by inappropriate electrolyte content. Divalent cations (e.g., calcium and magnesium) have been shown to cause emulsion instability.

RATE OF ADMINISTRATION

May be infused through a peripheral or central line. Solutions with an osmolarity of 900 mOsm/L or greater must be infused through a central vein. Administer through a dedicated peripheral or central line with a 1.2-micron in-line filter via a Y-connector located closest to the infusion site. Flow rates of both solutions (fat emulsion and dextrose–amino acid products) should be controlled by separate infusion pumps. Avoid multiple connections; do not connect multiple medications in series. Turn off pump before the bottle runs dry. A vented infusion set is used when fish oil emulsion is infused from the bottle. Use caution to avoid air embolism.

Fish oil triglycerides:

Initial rate of infusion should not exceed 0.05 mL/min for the first 15 to 30 minutes. If tolerated, gradually increase until reaching the required rate after 30 minutes. Maximum infusion rate should not exceed 1.5 mL/kg/hr, corresponding to 0.15 Gm/kg/hr. The recommended duration for infusion is between 8 and 24 hours depending on the clinical situation.

ACTIONS

A sterile, nonpyrogenic, white, homogenous emulsion for IV infusion that provides a biologically utilizable source of calories and essential fatty acids. Fatty acids serve as an important substrate for energy production. Fatty acids are also important for membrane structure and function, as precursors for bioactive molecules (such as prostaglandins), and as regulators of gene expression. Total energy content is 112 kcal/100 mL (1.12 kcal/mL), including lipids, phospholipids, and glycerol. Approximate osmolarity is 342 mOsm/kg water (which represents an osmolarity of 273 mOsm/L).

INDICATIONS AND USES

A source of calories and fatty acids in pediatric patients with parenteral nutrition–associated cholestasis (PNAC).

Limitations of use:

Not indicated for the prevention of PNAC. It has not been proven that fish oil triglycerides prevents PNAC in PN-dependent patients. ■ It has not been demonstrated that clinical outcomes observed in patients treated with this product are a result of the omega-6:omega-3 fatty acid ratio of the product.

CONTRAINDICATIONS

Known hypersensitivity to fish or egg protein or to any of the active ingredients or excipients. ■ Severe hemorrhagic disorders due to a potential effect on platelet aggregation. ■ Severe hyperlipidemia or severe disorders of lipid metabolism characterized by hypertriglyceridemia (serum triglyceride concentrations greater than 1,000 mg/dL).

PRECAUTIONS

Can be administered alone or as part of a PN admixture by central or peripheral IV infusion. When administered with dextrose and amino acids, the choice of a central or peripheral venous route should depend on the osmolarity of the final infusate. Solutions with an osmolarity of 900 mOsm/L or greater must be infused through a central vein. ■ Deaths in preterm infants due to pulmonary lipid accumulation after infusion of soybean oil–based IV lipid emulsions (e.g., Intralipid) have been reported. The risk of pulmonary lipid accumulation with fish oil triglycerides is unknown. ■ Preterm and small-for-gestational age infants have poor clearance of IV lipid emulsion and increased free fatty acid plasma levels following lipid emulsion infusion. Consider administration of less than the maximum recommended dose in these patients to decrease the likelihood of IV fat overload; see Monitor and Dose Adjustments. ■ Hypersensitivity reactions may occur. ■ Patients requiring PN may be at higher risk for infection (e.g., septicemia) due to malnutrition-associated immunosuppression, long-term use and poor maintenance of IV catheters, or immunosuppressive effects of other conditions or concomitant drugs. In addition, lipid emulsions can support microbial growth and are an independent risk factor for the development of bloodstream infections. ■ Fat overload syndrome has been reported (rare). Most frequently observed when the recommended lipid dose is exceeded but has occurred with correct dosing. Usually reversible when lipid emulsion infusion is stopped; see Monitor. ■ Administration of PN to severely undernourished patients may result in refeeding syndrome. ■ Impaired lipid metabolism with hypertriglyceridemia may occur in conditions such as inherited lipid disorders, obesity, diabetes mellitus, and metabolic syndrome. Serum triglyceride levels greater than 1,000 mg/dL have been associated with an increased risk of pancreatitis. ■ This product contains no more than 25 mcg/L of aluminum. With prolonged PN and impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. May occur at lower rates of administration. ■ Contains 0.15 to 0.3 mg/mL of di-alpha-tocopherol. Take this into account when determining the need for additional supplementation of vitamin E.

Monitor:

Obtain baseline values of blood glucose, electrolytes, blood coagulation parameters, liver and kidney function, serum triglycerides, CBC, and platelet count and monitor throughout treatment. ■ Correct severe water and electrolyte disorders. ■ Monitor for laboratory evidence of essential fatty acid deficiency (EFAD) ■ Measure serum osmolarity as indicated, especially in neonates. Discontinue use for significant abnormality. ■ Use of aseptic technique imperative in the preparation and administration of Fish Oil Emulsion and in catheter placement and maintenance. ■ Monitor for S/S of infection (e.g., chills, fever, laboratory test results that might indicate infection [including leukocytosis and hyperglycemia]) and frequently inspect the IV catheter insertion site for discharge, edema, and redness. ■ Monitor for S/S of pleural or pericardial effusion. ■ Monitor for S/S of a hypersensitivity reaction (e.g., altered mentation, bronchospasm, chills, cyanosis, dizziness, dyspnea, erythema, fever, flushing, headache, hypotension, hypoxia, nausea, rash, sweating, tachycardia, tachypnea, vomiting, urticaria). ■ Monitor for S/S of fat overload syndrome. Reduced or limited ability to metabolize and clear lipids may result in a sudden deterioration of patient condition accompanied by anemia, coagulation disorders, deteriorating liver function, fever, hepatomegaly, hyperlipidemia, leukopenia, thrombocytopenia, and CNS manifestations (e.g., coma). Serum triglycerides and/or plasma free fatty acid levels are monitored to assess infant's ability to eliminate infused fat from the circulation; must clear between daily infusions; see Dose Adjustments. ■ For severely undernourished patients initiating PN therapy, monitor closely for S/S of refeeding syndrome. May be characterized by the intracellular shift of potassium, phosphorus, and magnesium; thiamine deficiency; and fluid retention. Initiate PN therapy slowly and monitor closely.

Patient Education:

Inform parents that deaths in premature infants after infusion of IV fat emulsion have been reported. ■ Review other possible complications. ■ Laboratory monitoring is required. ■ Parents or pediatric patients should promptly report any S/S of hypersensitivity reactions (e.g., bronchospasm, chills, dyspnea, hypotension, hypoxia, nausea, rash, urticaria). ■ Parents or pediatric patients should promptly report any S/S of infection (e.g., fever, chills, pain at infusion site).

Maternal/Child:

Not intended for use in pregnancy, labor, or lactation. No data available. ■ Safety and effectiveness established for use in pediatric patients; see Precautions.

DRUG/LAB INTERACTIONS

Prolonged bleeding time has been reported in patients taking **antiplatelet agents** or **anticoagulants** (e.g., heparin) **and oral omega-3 fatty acids.** Prolongation of bleeding times in studies did not exceed normal limits, and there were no clinically significant bleeding episodes. Periodic monitoring of bleeding time in patients receiving concomitant antiplatelet agents or anticoagulants is recommended. ■ May interfere with some **laboratory blood tests** (e.g., bilirubin, hemoglobin, lactate dehydrogenase, and oxygen saturation) if blood is sampled before lipids have cleared from the bloodstream. Lipids are normally cleared after 5 to 6 hours once the lipid infusion is stopped.

SIDE EFFECTS

Agitation, apnea, bradycardia, viral infections, and vomiting are most common. Abscess, erythema, hypertonia, incision site erythema, neutropenia, and rash have been reported. Serious adverse reactions may include death due to pulmonary lipid accumulation, hypersensitivity reactions, infections, fat overload syndrome, refeeding syndrome, hypertriglyceridemia, and aluminum toxicity.

Post-Marketing:

Life-threatening hemorrhage following a central venous catheter change was reported in one infant with no prior history of bleeding, coagulopathy, or portal hypertension.

ANTIDOTE

Notify physician of all side effects. Many will be treated symptomatically. See Dose Adjustments. In the event of a hypersensitivity reaction, stop the infusion immediately and initiate appropriate treatment and supportive measures. For accidental overdose, stop the infusion. Obtain blood sample for inspection of serum triglyceride concentration. Repeat blood samples until the lipid has cleared. Lipids are not dialyzable.

FLUCONAZOLE

(flew-**KON**-ah-zohl)
Diflucan
Antifungal
(azole derivative)
pH 3.5 to 8

USUAL DOSE

Daily dose should be based on the infecting organism and the patient’s response to therapy. Treatment should be continued until clinical parameters or laboratory tests indicate that active fungal infection has subsided. IV dose has been used for a maximum of 14 days. Plasma levels are similar with IV or oral, so oral dose can replace IV dose at any time. See Monitor.

Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

Oropharyngeal candidiasis:

Initial dose of 200 mg followed by 100 mg/day for a minimum of 14 days. PO maintenance therapy usually required in AIDS patients to prevent relapse.

Esophageal candidiasis:

Initial dose of 200 mg followed by 100 mg/day for a minimum of 21 days and for at least 2 weeks after symptoms subside. Up to 400 mg/24 hr may be used.

Urinary tract or peritoneal candidiasis:

50 to 200 mg/day has been used.

Systemic candidiasis:

Optimum therapeutic dose and duration of therapy not established. Doses up to 400 mg/day have been used.

Treatment of acute cryptococcal meningitis:

Initial dose of 400 mg followed by 200 mg/day for a minimum of 10 to 12 weeks after CSF culture becomes negative.

Suppression of cryptococcal meningitis:

200 mg/day. Usually required in patients with AIDS to prevent relapse.

Prevention of candidiasis in bone marrow transplant:

400 mg/day. If severe neutropenia (less than 500/mm^3) is expected, begin fluconazole prophylaxis several days ahead of expected neutropenia. Continue for 7 days after neutrophils reach 1,000/mm^3.

PEDIATRIC DOSE

Experience with pediatric patients is limited; see Maternal/Child.

In pediatric patients, 3 mg/kg is equivalent to an adult dose of 100 mg, 6 mg/kg to 200 mg, and 12 mg/kg to 400 mg. Some older pediatric patients may have clearance similar to an adult. Do not exceed 600 mg/day.

Oropharyngeal candidiasis:

Initial dose of 6 mg/kg of body weight followed by 3 mg/kg/day for a minimum of 14 days.

Esophageal candidiasis:

Initial dose of 6 mg/kg of body weight followed by 3 mg/kg/day for a minimum of 21 days and for at least 2 weeks after symptoms subside. Up to 12 mg/kg has been used.

Systemic candidiasis:

6 to 12 mg/kg/day. See Comments in Usual Dose.

Treatment of acute cryptococcal meningitis:

Initial dose of 12 mg/kg of body weight followed by 6 mg/kg/day for a minimum of 10 to 12 weeks after CSF culture becomes negative. Up to 12 mg/kg/day has been used.

Suppression of cryptococcal meningitis:

6 mg/kg/day.

NEONATAL DOSE

Experience is limited to pharmacokinetic studies in premature newborns; see Maternal/Child.

Birth to 2 weeks of age in premature neonates:

Manufacturer suggests using pediatric doses and extending the intervals to once every 72 hours. Prolonged half-life is seen in premature newborns (gestational age 26 to 29 weeks). After 2 weeks, dose may be given every 24 hours.

DOSE ADJUSTMENTS

In all adult situations, the infecting organism and response to therapy may justify increased doses up to 400 mg daily. ■ After the initial loading dose, reduce each dose by 50% in patients with a CrCl at or less than 50 mL/min. ■ Give 100% of the recommended dose after each dialysis in patients receiving regular dialysis. ■ Dose reduction in pediatric patients with renal insufficiency should parallel that recommended for adults. ■ See Drug/Lab Interactions.

DILUTION

Packaged prediluted and ready for use as an iso-osmotic solution containing 2 mg/mL in both glass bottles and Viaflex Plus plastic containers. Do not remove moisture barrier overwrap of plastic container until ready for use. Tear overwrap down side at slit to open, and remove sterile inner bag. Plastic may appear somewhat opaque due to sterilization process but will clear. Squeeze inner bag firmly to check for leaks. Discard if leakage noted; sterility is impaired. Do not use if cloudy or precipitated.

Storage:

Store glass bottles between 5° C (41° F) and 30° C (86° F); store plastic containers between 5° C (41° F) and 25° C (77° F). Protect both from freezing.

COMPATIBILITY

Manufacturer states, “Do not add supplementary medication.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as a continuous infusion at a rate not to exceed 200 mg/hr. Do not use plastic containers in series connections; air embolism could result.

ACTIONS

A synthetic, broad-spectrum, bis-Triazole antifungal agent. Inhibits fungal growth of *Candida* and *Cryptococcus neoformans* by acting on a key enzyme and depriving the fungus of ergosterol; the cell membrane becomes unstable and can no longer function normally. Human sterol synthesis is not affected. Peak plasma concentrations achieved in 1 to 2 hours; half-life extends for 30 hours (range 20 to 50 hours). Administration of a loading dose (on Day 1) of twice the usual daily dose results in a plasma concentration close to steady state by Day 2 when given IV or PO. Penetrates into all body fluids studied (see prescribing information) in similar and effective concentrations and remains constant with daily single-dose administration. 80% excreted as unchanged drug and about 11% excreted as metabolites in the urine. Secreted in breast milk.

INDICATIONS AND USES

Oropharyngeal and esophageal candidiasis. ■ Serious candidal infections, including GU tract infections, peritonitis, and systemic Candida infections including candidemia, disseminate candidiasis, and pneumonia. May be an appropriate and less toxic alternative to amphotericin B. ■ Cryptococcal meningitis, including suppressive therapy to prevent relapse. ■ Prevention of candidiasis in bone marrow transplant patients. ■ Used orally for additional indications (e.g., candidiasis prophylaxis).

Unlabeled uses:

Has been used in many other fungal or parasitic infections.

CONTRAINDICATIONS

Hypersensitivity to fluconazole or any of its components. Use caution in patients hypersensitive to other azoles (e.g., ketoconazole). ■ Coadministration with drugs known to prolong the QT interval that are metabolized via the enzyme CYP3A4, such as erythromycin, pimozide, and quinidine.

PRECAUTIONS

For IV use only; do not give IM. ■ Specimens for fungal culture and serologic and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. ■ Inadequate treatment may lead to a recurrence of active infection; continue treatment until clinical parameters or laboratory tests indicate that active fungal infection has subsided. See specific recommendations in Usual Dose. ■ Use caution in patients with pre-existing liver disease. ■ Serious hepatotoxicity may occur. Causal relationship uncertain, but many patients are taking hepatotoxic drugs for treatment of malignancies and AIDS. Note any abnormal liver function tests (e.g., AST). If any clinical signs and symptoms consistent with liver disease develop, discontinue drug. Has caused deaths. ■ Associated with prolongation of the QT interval. Rare cases of torsades de pointes have been reported. More common in seriously ill patients with multiple confounding factors, such as heart disease, electrolyte abnormalities, and concomitant medications that may have been contributory (e.g., Class IA antiarrhythmic agents [e.g., quinidine, procainamide] and Class III antiarrhythmic agents [e.g., amiodarone, sotalol]). ■ Exfoliative skin disorders have been reported. Fatalities have occurred in patients with serious underlying diseases. ■ Use with caution in patients with renal dysfunction; see Dose Adjustment. ■ Anaphylaxis has been reported rarely. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline liver function tests and SCr; monitor periodically during treatment. ■ Observe for S/S of hypersensitivity or skin reactions. Closely monitor patients with deep-seated fungal infections who develop rashes; discontinue fluconazole if lesions progress; see Antidote. ■ Consider ECG monitoring in patients at risk for QT prolongation. ■ See Drug/Lab Interactions.

Patient Education:

May cause serious problems with selected medications; review prescription and nonprescription drugs with physician or pharmacist. ■ May cause dizziness or seizures. Do not drive or operate hazardous machinery until effects of fluconazole are known.

Maternal/Child:

Category D: safety for use in pregnancy and breast-feeding not established. There have been rare cases of distinct congenital anomalies in infants exposed in utero to high-dose maternal fluconazole during most or all of the first trimester. ■ Use caution if administered to nursing mothers. ■ Safety profile has been studied in pediatric patients ages 1 day to 17 years. Efficacy in pediatric patients under 6 months of age has not been established. However, a small number of patients ranging from age 1 day to 6 months have been treated safely (unlabeled).

Elderly:

Differences in response compared to younger adults not identified; however, may be at increased risk for side effects (e.g., acute renal failure, anemia, diarrhea, rash, and vomiting). ■ Use caution; consider decreased cardiac, hepatic, or renal function and effects of concomitant disease or other drug therapy. ■ See Dose Adjustments and Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

A potent CYP2C9 inhibitor and a moderate CYP3A4 inhibitor. Closely monitor patients who are treated concomitantly with **drugs with a narrow therapeutic index metabolized by CYP2C9 or CYP3A4.** The enzyme-inhibiting effect of fluconazole can last for 4 to 5 days after it is discontinued. ■ Avoid concurrent use with **erythromycin**; may increase the risk of cardiotoxicity (prolonged QT interval, torsades de pointes) and, consequently, sudden death. ■ Potentiated by **hydrochlorothiazide**; decreases renal clearance of fluconazole. ■ Inhibits metabolism and increases serum levels of **phenytoin, sirolimus, oral tacrolimus, and theophyllines;** careful monitoring of their plasma levels is required; nephrotoxicity has been reported with tacrolimus. ■ Inhibits metabolism and increases serum levels of **cyclosporine**. Monitor levels and SCr. Cyclosporine dose reduction may be indicated with concomitant use. ■ Potentiates **warfarin**; monitor PT and INR frequently. ■ Potentiates **sulfonylureas**; monitor blood glucose levels. Adjust the dose of the oral hypoglycemic agent as indicated. ■ **Rifampin** increases metabolism; fluconazole dose may need to be increased. One source recommends avoiding concurrent use. ■ Increases serum levels of **zidovudine**. Dose reduction may be necessary. ■ Increases serum levels of **rifabutin**. Uveitis has been reported in patients receiving rifabutin and fluconazole concomitantly. Monitoring is recommended. ■ Risk of cardiac arrhythmias increased with **erythromycin, pimozide**, and **quinidine**; concurrent use not recommended; see Contraindications. ■ Fluconazole may inhibit metabolism and increase plasma concentrations of **carbamazepine**; monitor carbamazepine concentrations. ■ Avoid concomitant use with **voriconazole**. Potential for voriconazole toxicity remains if voriconazole is initiated within 24 hours of the last dose of fluconazole. ■ May decrease metabolism and increase serum concentrations of **celecoxib** and other **NSAIDs**. Monitor for toxicity related to NSAIDs and adjust dose as needed. ■ May decrease metabolism and increase serum concentrations of **selected benzodiazepines** that are metabolized by the cytochrome P_{450} system. ■ May increase serum concentrations and adverse effects of **alfentanil, buspirone, calcium channel blockers, corticosteroids, fentanyl, haloperidol, methadone, nisoldipine, tolterodine, tricyclic antidepressants, and vinca alkaloids** (e.g., vincristine). Reduce doses of the above drugs as indicated to avoid toxicity. Dose may need to be increased when fluconazole is discontinued. **Tolterodine** dose should be limited to no more than 1 mg twice daily when coadministered with fluconazole. ■ Inhibits metabolism of **losartan** to its active metabolite. Monitor BP closely. ■ Coadministration may increase plasma levels of some **protease inhibitors** (e.g., nelfinavir, saquinavir), increasing the risk of toxicity. ■ Increases serum levels of **HMG-CoA reductase inhibitors**; rhabdomyolysis has been reported. **Pravastatin** levels may be the least affected. ■ Increases systemic exposure to **tofacitinib**. Dose reduction required with coadministration; see tofacitinib prescribing information. ■ May increase the plasma concentrations and therapeutic effects of **zolpidem**. ■ An increase in serum bilirubin and creatinine has been observed with concurrent use of **cyclophosphamide** and fluconazole. Use caution and monitor if combined use is required. ■ No significant pharmacokinetic interaction between fluconazole and **azithromycin** has been observed. ■ May **elevate liver function tests** (e.g., ALT, AST, alkaline phosphatase, and bilirubin).

SIDE EFFECTS

Abdominal pain, diarrhea, dizziness, dry mouth, dyspepsia, exfoliative skin disorders, headache, hepatic reactions, hypercholesterolemia, hypersensitivity reactions (including anaphylaxis with angioedema, face edema, and pruritus), hypertriglyceridemia, hypokalemia, increased appetite, increased sweating, leukopenia (including neutropenia and agranulocytosis), nausea, pallor, QT prolongation, rash, seizures, taste perversion, thrombocytopenia, torsades de pointes, tremor, vomiting.

Overdose:

Cyanosis, decreased motility, decreased respirations, hallucinations, lacrimation, loss of balance, salivation, urinary incontinence. Clonic convulsions preceded death in experimental animals. Changes in renal and hematologic function test results and hepatic abnormalities have been seen in some patients, particularly those with serious underlying diseases such as AIDS and cancer. Clinical significance and relationship to treatment are unclear.

Post-Marketing:

Asthenia, cholestasis, fatigue, fever, hepatocellular damage, insomnia, malaise, myalgia, paresthesia, somnolence.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Discontinue drug and notify physician of abnormal liver function tests progressing to clinical signs and symptoms of liver disease. Rash may be the first sign of an exfoliative skin disorder in immunocompromised patients; discontinue drug and notify physician. In overdose a 3-hour dialysis session will decrease plasma levels by 50%. Treat anaphylaxis or resuscitate if indicated.

FLUDARABINE PHOSPHATE BBW

(floo-**DAIR**-ah-bean **FOS**-fayt)
Fludara
Antineoplastic (antimetabolite)
pH 7.2 to 8.2 (lyophilized)
pH 7.3 to 7.7 (liquid)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Fludarabine:

25 mg/M^2/day for 5 consecutive days. Repeat every 4 weeks. Optimum duration of treatment not established. If there is no major toxicity, treat until maximum response achieved, then administer three additional complete cycles.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established; see Maternal/Child.

Pediatric acute lymphocytic leukemia (ALL) patients (unlabeled):

Give an initial loading bolus of 10.5 mg/M^2 on Day 1 followed by a continuous infusion of 30.5 mg/M^2/day on Days 1 through 5.

Pediatric patients with solid tumors (unlabeled):

Dose-limiting myelosuppression was observed with a loading dose of 8 mg/M^2 on Day 1 followed by a continuous infusion of 23.5 mg/M²/day on Days 1 through 5. Maximum tolerated dose in solid tumor pediatric patients was a loading dose of 7 mg/M²/day followed by a continuous infusion of 20 mg/M²/day for 5 days.

DOSE ADJUSTMENTS

Decrease or delay dose based on evidence of hematologic or nonhematologic toxicity. Increased toxicity may occur in the elderly and in patients with renal insufficiency or bone marrow impairment. Monitor closely and adjust dose as indicated. ■ Adjust initial starting doses for patients with renal impairment as indicated in the following chart.

Fludarabine Starting Dose Adjustment for Renal Impairment	
Creatinine Clearance	**Starting Dose**
≥80 mL/min	25 mg/M² (full dose)
50–79 mL/min	20 mg/M²
30–49 mL/min	15 mg/M²
<30 mL/min	Do not administer

DILUTION

Specific techniques required; see Precautions**.** Available as a sterile solution 50 mg/2 mL (25 mg/mL) or as a lyophilized solid cake (50 mg) requiring reconstitution with 2 mL of SWFI (25 mg/mL). Should dissolve within 15 seconds. In clinical studies, each single dose was further diluted in 100 to 125 mL of NS or D5W and given as an infusion over 30 minutes.

Filters:

Specific information from studies not available; contact manufacturer for further information.

Storage:

Refrigerate between 2° and 8° C (36° to 46° F) before dilution. No preservative; use within 8 hours of dilution.

COMPATIBILITY

Manufacturer states, “Should not be mixed with other drugs.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Single daily dose properly diluted for infusion over 30 minutes.

ACTIONS

A potent antineoplastic agent. A fluorinated nucleotide analog of the antiviral agent vidarabine. Rapidly converts to the active metabolite 2-fluoro-ara-ATP and interferes with the synthesis of DNA. Actual mechanism of action unknown and may be multifaceted. Median time to response in studies of patients with refractory chronic lymphocytic leukemia (CLL) was 7 to 21 weeks (range 1 to 68 weeks). Elimination half-life is approximately 20 hours. Total body clearance of the active metabolite is correlated with the CrCl, indicating the importance of renal excretion for drug elimination.

INDICATIONS AND USES

Treatment of patients with B-cell CLL who have not responded to or progressed during treatment with at least one standard alkylating agent–containing regimen. ■ Safety and effectiveness in previously untreated or nonrefractory patients with CLL not established.

Unlabeled uses:

Treatment of non-Hodgkin lymphoma, acute lymphocytic leukemia, acute myeloid leukemia, prolymphocytic leukemia or prolymphocytoid variant of CLL, mycosis fungoides, hairy-cell leukemia, and Waldenström's macroglobulinemia. Dose and/or efficacy not established.

CONTRAINDICATIONS

Hypersensitivity to fludarabine or its components (e.g., mannitol and sodium hydroxide). ■ Not recommended for use in patients with severely impaired renal function (CrCl less than 30 mL/min). ■ Not recommended for use in combination with pentostatin (Nipent); see Drug/Lab Interactions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Use with caution in advanced age, renal insufficiency, or bone marrow impairment, or in patients with immunodeficiency or a history of opportunistic infection. ■ Severe myelosuppression (anemia, neutropenia, and thrombocytopenia) is common. Median time to nadir counts was 13 days for granulocytes and 16 days for platelets. ■ Most patients have hematologic impairment at baseline because of disease or prior myelosuppressive therapy. Myelosuppression may be severe and cumulative. ■ Several instances of trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia, sometimes resulting in death, have been reported. Clinically significant cytopenias lasted from 2 months to 1 year and occurred in untreated and previously treated patients. ■ Use of irradiated blood product is recommended for patients requiring transfusions during fludarabine therapy because transfusion-associated graft-versus-host disease has been reported. ■ Use caution in patients with large tumor burdens; may cause tumor lysis syndrome. Response can occur within 1 week. ■ Life-threatening and sometimes fatal cases of autoimmune phenomena, such as hemolytic anemia, autoimmune thrombocytopenia/thrombocytopenic purpura (ITP), Evans syndrome, and acquired hemophilia, have been reported; see Antidote. ■ Serious, sometimes fatal infections, including opportunistic infections and reactivations of latent viral infections (e.g., varicella zoster virus [VZV], Epstein-Barr virus, and JC virus [progressive multifocal leukoencephalopathy]), as well as disease progression and transformation (e.g., Richter's syndrome) have been reported. ■ Severe neurotoxicity characterized by delayed blindness, coma, and death has been reported in patients who received doses that were approximately 4 times greater than the recommended dose. Significant neurotoxicity has also been reported in patients receiving doses in the recommended range. Symptoms may appear 7 to 225 days after the last dose. ■ Do not administer **live virus vaccines** during or after treatment with fludarabine. ■ See Side Effects.

Monitor:

Observe closely for signs of toxicity, both hematologic and nonhematologic. ■ Obtain baseline CBC, including differential and platelet count. Repeat regularly to monitor hematopoietic suppression (especially neutrophils and platelets) and hemolysis. ■ Obtain baseline CrCl. ■ Observe closely for all signs of infection and any fever of unknown origin. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Consider prophylactic therapy in patients at risk for developing opportunistic infections. ■ Nausea and vomiting usually less severe than with many other antineoplastics; prophylactic administration of antiemetics may be indicated. ■ Monitor for early signs of tumor lysis syndrome (e.g., flank pain, hematuria). Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol [Aloprim]). ■ Monitor for evidence of hemolysis. ■ Monitor for S/S of neurotoxicity (e.g., agitation, coma, confusion, seizures). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Avoid pregnancy; effective birth control recommended for both males and females during therapy and for at least 6 months after fludarabine regimen has been completed. ■ Use caution while driving or operating machinery. Agitation, confusion, fatigue, seizures, visual disturbances, and weakness have been reported. ■ Adherence to periodic blood count monitoring is imperative. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: both males and females should use effective contraception and avoid pregnancy; may cause fetal harm; see Patient Education. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established; however, data have been submitted to the FDA using the doses described under Pediatric Dose. In pediatric patients, platelet counts appeared to be more sensitive than hemoglobin and WBCs to the effects of fludarabine.

Elderly:

See Precautions and Dose Adjustments.

DRUG/LAB INTERACTIONS

Do not use with pentostatin (Nipent); may increase risk of fatal pulmonary toxicity. ■ Do not administer **live virus vaccines** during or after treatment with fludarabine.

SIDE EFFECTS

Are frequent, may be dose limiting, and may cause death. The most common side effects include myelosuppression (anemia, neutropenia, thrombocytopenia), chills, cough, diarrhea, fatigue, fever, infection (including opportunistic and pneumonia), mucositis, nausea and vomiting, and weakness. The most serious side effects include CNS toxicity, hemolytic anemia, pulmonary toxicity, and severe bone marrow suppression. Other reported side effects include agitation, anorexia, arrhythmia, bone marrow aplasia or hypoplasia (may result in pancytopenia), cerebral hemorrhage, coma, confusion, dyspnea, dysuria, edema, elevated hepatic enzymes, esophagitis, GI bleeding/hemorrhage, headache, heart failure, hemorrhagic cystitis, infection, malaise, myalgia, pain, paresthesia, peripheral neuropathy, pulmonary toxicity (ARDS, dyspnea, interstitial pulmonary infiltrate, pulmonary fibrosis, pulmonary hemorrhage, respiratory distress and failure), rashes, seizures, sinusitis, stomatitis, visual disturbances. Onset of flank pain and hematuria may indicate tumor lysis syndrome (hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure); one reported.

Overdose:

Severe bone marrow suppression (neutropenia and thrombocytopenia). Severe neurologic toxicity including delayed blindness, coma, and death occurred from 21 to 60 days after the last dose in 36% of patients treated with doses only 4 times greater than the recommended dose. Has occurred (in no more than 0.2% of patients) with average doses.

Post-Marketing:

Erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, and pemphigus (some with fatal outcomes); rare cases of myelodysplastic syndrome and acute myeloid leukemia associated with prior, concomitant, or subsequent treatment with alkylating agents, topoisomerase inhibitors (e.g., irinotecan [Camptosar]), or irradiation; progressive multifocal leukoencephalopathy (PML) within a few weeks to a year (most with a fatal outcome; some patients had prior and/or concurrent chemotherapy); trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia and death; and worsening or flare-up of pre-existing skin cancer lesions and/or new onset of skin cancer during or after treatment with fludarabine.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Some toxicity is necessary to produce remission. Delay or discontinue the drug for serious hematologic depression. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Restart as soon as signs of bone marrow recovery occur. Delay or discontinue if neurotoxicity occurs. There is no specific antidote; supportive therapy as indicated will help sustain the patient in toxicity. Symptoms of pulmonary toxicity may improve with the use of corticosteroids; rule out an infectious origin before use. Steroids may or may not be useful in controlling hemolytic episodes.

FLUMAZENIL BBW

(floo-**MAZ**-eh-nill)
Romazicon
Benzodiazepine antagonist
Antidote
pH 4

USUAL DOSE

Pretreatment:

See Monitor.

Reversal of conscious sedation or in general anesthesia:

0.2 mg (2 mL) as an initial dose. Assess level of consciousness. May be repeated at 1-minute intervals, assessing level of consciousness between each dose, until desired level of consciousness achieved or a total cumulative dose of 1 mg (10 mL) has been given (average dose to awakening is 0.6 mg to 1 mg). If resedation occurs (may occur if flumazenil wears off before the benzodiazepine), the above process may be repeated at 20-minute intervals as indicated. Do not give more than a cumulative dose of 1 mg in a 20-minute period or 3 mg in any 1 hour.

Management of suspected benzodiazepine overdose:

0.2 mg (2 mL) as an initial dose. Assess level of consciousness. If results inadequate, give an additional dose of 0.3 mg (3 mL) in 1 minute. If results are still inadequate, 0.5 mg (5 mL) may be repeated at 1-minute intervals. Assess level of consciousness between each dose until desired level of consciousness achieved or a total cumulative dose of 3 mg (30 mL) has been given (average dose to awakening is 1 mg to 3 mg). If a partial response is achieved with 3 mg, continue dosing in 0.5-mg increments until awakening or a cumulative dose of 5 mg is reached (rarely required). If patient has not responded to a cumulative dose of 5 mg within 5 minutes, benzodiazepines are not the major cause of sedation; discontinue use. If desired results are achieved and resedation occurs (expected), no more than 1 mg given in 0.5-mg increments may be given in any 20-minute period and no more than a cumulative total dose of 3 mg in any 1 hour.

PEDIATRIC DOSE

Reversal of conscious sedation:

0.01 mg/kg (up to 0.2 mg). Assess level of consciousness. May repeat at 1-minute intervals, assessing level of consciousness between each dose until desired level of consciousness achieved or a maximum total dose of 0.05 mg/kg (or 1 mg) has been given. Mean total dose administered in trials was 0.65 mg. See Maternal/Child.

DOSE ADJUSTMENTS

Not required for the elderly. ■ Reduce dose and extend intervals after the initial dose in impaired liver function. ■ Individualize dose in high-risk patients. Administer the smallest amount that is effective and wait for peak effect (6 to 10 minutes). Slower titration rates and lower total doses may be especially important in these patients (see Precautions) to reduce emergent confusion and agitation, to prevent seizures, and to evaluate effect.

DILUTION

May be given undiluted through a free-flowing IV into a large vein (to minimize pain at injection site). **Compatible** with D5W, D2½W, LR, ½NS, and NS if further dilution required by a specific situation.

Storage:

Store unopened vials at CRT. Discard in 24 hours if drawn undiluted into a syringe or diluted in any solution.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Series of small injections allows control of the reversal of sedation to desired endpoint, avoids abrupt awakening, and minimizes the possibility of adverse effects. Rapid injection may cause withdrawal symptoms in patients with long-term exposure to benzodiazepines.

Reversal of conscious sedation or in general anesthesia:

Each single dose over 15 seconds.

Management of suspected benzodiazepine overdose:

Each single dose (0.2 mg [2 mL], 0.3 mg [3 mL], 0.5 mg [5 mL], respectively) is given over 30 seconds.

ACTIONS

A benzodiazepine antagonist. Competes with benzodiazepines, inhibiting their effect at benzodiazepine receptor sites. Action is very specific and reverses the effects of benzodiazepines only. Antagonizes (reverses) the sedation, impairment of recall, psychomotor impairment, and ventilatory depression produced by benzodiazepines. Duration and degree of reversal are related to dose and plasma concentration (both for amount of benzodiazepine and amount of flumazenil). Onset of action usually occurs within 1 to 2 minutes of reaching the appropriate dose, with peak effect at 6 to 10 minutes. Enables the physician to control the duration of action of benzodiazepines and to evaluate the patient’s postoperative condition earlier and may facilitate the postprocedural course. In overdose, it allows the physician to communicate sooner with patients who have taken an excessive dose. Extensively metabolized in the liver. Half-life is 40 to 80 minutes. Excreted in changed form in urine and to a small extent in feces.

INDICATIONS AND USES

Adults:

Complete or partial reversal of the effects of general anesthesia induced and/or maintained with benzodiazepines (e.g., diazepam, midazolam). ■ Complete or partial reversal of the sedative effects of benzodiazepines used to produce and/or maintain conscious sedation (e.g., diagnostic and therapeutic procedures). ■ Adjunct to conventional treatment in managing benzodiazepine overdose (e.g., diazepam, lorazepam, midazolam).

Pediatric patients 1 to 17 years of age:

Reversal of conscious sedation induced with benzodiazepines; see Maternal/Child. ■ Not approved for other indications but has been used at doses similar to those used for reversal of conscious sedation; see Maternal/Child.

CONTRAINDICATIONS

Known hypersensitivity to flumazenil or any benzodiazepine, patients who are on benzodiazepine therapy for control of potentially life-threatening conditions (e.g., control of intracranial pressure, status epilepticus), and patients showing signs of serious cyclic antidepressant overdose. ■ Use in treatment of benzodiazepine dependence is not recommended.

PRECAUTIONS

Excess administration increases risk of side effects and decreases desired therapeutics of benzodiazepines. ■ Will not reverse the central nervous system (CNS) effects of drugs such as alcohol, analgesics, antidepressants, barbiturates, and narcotics. In overdose, will bring the patient to a conscious state only if a benzodiazepine is responsible for the sedation. Has reversed benzodiazepine-induced hypotension and bradycardia unresponsive to other measures (e.g., IV fluids, atropine, dopamine). ■ Convulsions may occur, especially in patients who rely on benzodiazepines to control seizures or are physically dependent on benzodiazepines for long-term sedation, in overdose cases in which patients are showing signs of serious cyclic antidepressant overdose (some clinicians recommend a diagnostic ECG or quantitative analytical testing before use—see Contraindications), or in ICU patients who may have an unrecognized dependence on benzodiazepines because of frequent use as a sedative (can occur with only 3 to 5 days of benzodiazepine administration). Intubation with ventilatory and circulatory support may be the treatment of choice for these high-risk patients; see Dose

Adjustments. ■ Risk of adverse reactions increased in patients with a history of alcohol, benzodiazepine, or sedative use (increased frequency of benzodiazepine tolerance and dependence). Can precipitate benzodiazepine withdrawal (also high-risk; see Dose Adjustments). ■ Use extreme caution in head injury (may alter cerebral blood flow or cause convulsions). ■ Do not use until effects of neuromuscular blockade have been fully reversed. ■ May cause panic attacks in patients with a history of panic disorder. ■ Flumazenil may not completely reverse respiratory depression due to benzodiazepines in patients with serious lung disease. Additional ventilatory support may be required. ■ Half-life prolonged based on amount of hepatic impairment. ■ Ingestion of food increases clearance of flumazenil.

Monitor:

Confirm secure airway, ventilation, and IV access before administration as indicated. ■ Monitor BP, HR, and respirations closely. ECG monitoring and oxygenation determination by pulse oximetry is recommended. ■ Emergency equipment and supplies, including drugs for seizure control (see Antidote), must always be available. ■ Observe continuously for resedation, respiratory depression, preseizure activity, or other residual benzodiazepine effects for an appropriate period (2 or more hours). ■ Extend observation time for larger doses, in presence of long-acting benzodiazepines (e.g., diazepam [Valium]), or large doses of short-acting benzodiazepines (e.g., more than 10 mg of midazolam [Versed]). ■ Observe ambulatory patients for a minimum of 2 hours after a 1-mg dose; resedation after 2 hours is unlikely. Extend observation time as above. ■ Awake patients may require pain medication sooner than those without benzodiazepine reversal. ■ All postprocedural instructions must be given to the patient verbally and in writing; does not reverse benzodiazepine amnesia. ■ See Drug/Lab Interactions.

Patient Education:

Review medication use, especially benzodiazepine, alcohol, and sedative use prior to surgery or procedure. ■ Effects of benzodiazepines may recur; for 24 to 48 hours memory and judgment may be impaired. ■ All instructions should be in writing. ■ Do not drive, operate hazardous machinery, or engage in activities that require alertness. ■ Do not take alcohol, other CNS depressants (e.g., antihistamines, barbiturates), or nonprescription drugs for 24 hours.

Maternal/Child:

Category C: use only if benefit justifies risk. ■ Not recommended during labor and delivery because effect on newborn unknown. ■ Safety for use in breast-feeding not established. ■ Safety and effectiveness for reversal of conscious sedation induced with benzodiazepines have been established in pediatric patients 1 to 17 years of age. Resedation may occur, especially in pediatric patients 1 to 5 years of age. Safety and effectiveness of repeated flumazenil doses in pediatric patients experiencing resedation have not been established. ■ Safety and effectiveness for other uses listed under adult indications have not been established. However, published anecdotal reports have cited safety profiles and dosing guidelines similar to those used in reversal of conscious sedation. ■ Half-life appears to be shorter and more variable in pediatric patients.

Elderly:

See Dose Adjustments. Age-related differences in safety and effectiveness have not been observed; however, a greater sensitivity of some older patients cannot be ruled out. ■ Monitor carefully; benzodiazepine-induced sedation may be deeper and more prolonged.

DRUG/LAB INTERACTIONS

May cause cardiac arrhythmias or convulsions in cases of mixed drug overdose. These toxic effects may emerge, especially with **tricyclic antidepressants** with the reversal of benzodiazepine effect; see Precautions. May reverse sedative and anticonvulsant effects. ■ May precipitate withdrawal symptoms if given to chronic **benzodiazepine** users. ■ No specific deleterious interactions noted when flumazenil administered after **narcotics, inhalational anesthetics, muscle relaxants, and muscle relaxant antagonists** administered in conjunction with sedation or anesthesia. ■ Not recommended for use in **epileptic patients** who have been receiving benzodiazepines for a prolonged period. ■ Lab test interactions have not been evaluated.

SIDE EFFECTS

Most common at doses above 1 mg and/or with abrupt reversal.

Abnormal vision, agitation, anxiety, dizziness, dry mouth, dyspnea, emotional lability, fatigue, flushing, headache, hot flashes, hypertension, hyperventilation, insomnia, involuntary movements, irritability, muscle tension, nausea, pain or reaction (rash, thrombophlebitis) at the injection site, palpitations, panic, paresthesia, sweating, tachycardia, tinnitus, tremors, and vomiting. Convulsions, fear, and panic attacks may occur; see Precautions. Deaths have been reported. Risk increased in patients with serious underlying disease or in patients who overdose on nonbenzodiazepine drugs (usually cyclic antidepressants).

Overdose:

Agitation, anxiety, arrhythmias, convulsions, hyperesthesia, increased muscle tone.

ANTIDOTE

Notify the physician of any side effect. Treat symptoms of benzodiazepine withdrawal (agitation, confusion, dizziness, emotional lability, or sensory distortions) with a barbiturate, benzodiazepine, or other sedative. Larger doses may be required because of presence of flumazenil. Treat convulsions from overdose with barbiturates, benzodiazepines, and phenytoin. Maintain an adequate airway, adequate ventilation, and IV access at all times. Hemodialysis not effective in overdose if 1 hour has passed since administration.

FLUOROURACIL BBW

(flew-roh-**YOUR**-ah-sill)
Adrucil, 5-Fluorouracil, 5-FU
Antineoplastic (antimetabolite)

pH 9.2

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Fluorouracil:

Many dosing regimens are in use. May be given as an injection or as a continuous infusion. Manufacturer recommends 12 mg/kg of body weight/24 hr for 4 days. Total dose should not exceed 800 mg/24 hr. If no toxicity is observed, one-half dose (6 mg/kg) is given on Days 6, 8, 10, and 12 unless toxicity occurs. No medication is given on Days 5, 7, 9, or 11. Discontinue therapy on Day 12, even if no toxicity is apparent. See Precautions/Monitor. The most common form of maintenance therapy is to repeat the entire course of therapy beginning 30 days after the previous course is completed and any toxicity has subsided or to give a single dose of 10 to 15 mg/kg/week, not to exceed 1 Gm/week. Dose adjustments of subsequent doses are made depending on side effects and tolerance.

Advanced colorectal cancer (unlabeled dose):

Various protocols have been used. Examples are leucovorin calcium 20 mg/M^2 followed by fluorouracil 425 mg/M^2, or leucovorin calcium 200 mg/M^2 followed by fluorouracil 370 mg/M^2 daily for 5 days. Repeat at 4-week intervals twice, then repeat every 28 to 35 days based on complete recovery from toxic effects. Do not initiate or continue in any patient with GI toxicity until completely subsided. Reduce fluorouracil dose based on tolerance to previous course; reduce 20% for moderate hematologic or GI toxicity, 30% for severe toxicity. Increase fluorouracil dose 10% if no toxicity. Leucovorin calcium dose is not adjusted. Alternatively, fluorouracil may also be used in combination with levoleucovorin; dose is different; see levoleucovorin monograph. Fluorouracil and leucovorin calcium are also used in combination with irinotecan (Camptosar); see irinotecan monograph.

Breast cancer (unlabeled dose):

Various protocols have been used. An example is fluorouracil 600 mg/M^2 on Days 1 and 8 of each cycle combined with cyclophosphamide (Cytoxan) 100 mg/M^2 on Days 1 through 14 of each cycle and methotrexate 40 mg/M^2 on Days 1 and 8 of each cycle. Repeat cycles monthly (allowing a 2-week rest between cycles). Repeat for 6 to 12 cycles (6 to 12 months). Doxorubicin (Adriamycin) has also been included in this regimen. In patients older than 60 years of age, reduce the fluorouracil dose to 400 mg/M^2 and the initial methotrexate dose to 30 mg/M^2.

DOSE ADJUSTMENTS

For poor-risk patients or those in a poor nutritional state, either reduce dose by one-half or more throughout a course of therapy or give 6 mg/kg/day for 3 days. If no toxicity observed, give 3 mg/kg on Days 5, 7, and 9. Give nothing on Days 4, 6, or 8. Do not exceed 400 mg/day. ■ Dose based on ideal body weight in presence of edema, ascites, or obesity. ■ Reduce dose in patients who have received high-dose pelvic irradiation or other cytotoxic drug therapy with alkylating agents (e.g., cisplatin, ifosfamide). ■ One source recommends a dose adjustment in patients with impaired hepatic function. Give the full dose if the bilirubin is 5 or less on the day of administration; omit the dose if the bilirubin is greater than 5. ■ Used with other antineoplastic drugs in reduced doses to achieve tumor remission. ■ See Usual Dose.

DILUTION

***Specific techniques required; see* Precautions.** May be slightly discolored without affecting safety and potency. Dissolve any precipitate by heating to 60° C (140° F) and shaking vigorously. Let cool to body temperature before using.

IV injection:

May be given undiluted. May inject through Y-tube or three-way stopcock of a free-flowing infusion.

Infusion:

May be further diluted with D5W or NS and given as an infusion. Doses up to 2 Gm are being given with extreme caution under the specific supervision of experienced specialists. Leucovorin calcium has been mixed into the solution with fluorouracil.

Storage:

Store at room temperature; protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 1 to 15 minutes.

Infusion:

A single dose is usually administered over 24 hours. Toxicity may be lessened by extended administration.

ACTIONS

An antimetabolite. A fluorinated pyrimidine antagonist, cell cycle specific, that interferes with the synthesis of DNA and RNA. Through various chemical processes this deprivation acts more quickly on rapidly growing cells and causes their death. Distributes into tumors, intestinal mucosa, bone marrow, liver, and readily crosses the blood-brain barrier into cerebrospinal fluid and brain tissue. Metabolized by the liver within 3 hours. Half-life is approximately 16 minutes. Excretion is through the urine and as respiratory CO_2.

INDICATIONS AND USES

To suppress or slow neoplastic growth. Palliative treatment of cancers of the breast, colon, pancreas, rectum, and stomach. May be used alone or in combination with other agents.

Unlabeled uses:

Has been used for the treatment of bladder, cervical, endometrial, esophageal, head and neck, ovarian, prostatic, skin (topical), and other cancers. Consult oncology literature for protocols in use.

CONTRAINDICATIONS

Potentially serious infections, depressed bone marrow function, poor nutritional state, hypersensitivity, major surgery within the previous month.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. Hospitalization, at least during the initial course of therapy, is recommended. ■ Use caution in patients who have had high-dose pelvic irradiation, previous alkylating agents (e.g., cisplatin), other antimetabolic drugs (e.g., methotrexate), metastatic tumor involvement of the bone marrow, impaired hepatic or renal function, or dihydropyrimidine dehydrogenase deficiency. ■ Pseudomembranous colitis has been reported. May range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with fluorouracil.

Monitor:

Confirm patency of vein. Avoid extravasation. Change peripheral injection site every 48 hours. ■ Obtain a CBC with differential and platelet count before each dose. When given with leucovorin calcium, repeat weekly the first two courses and then at the time of anticipated WBC nadir in following courses. Electrolytes and liver function tests should be done before the first three courses, then every other course. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Examine mouth and lips daily for sores or other signs of stomatitis. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Toxicity increased by any form of therapy that adds to stress, poor nutrition, and bone marrow suppression. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ See Drug/Lab Interactions.

Patient Education:

Effective birth control recommended. ■ See Appendix D, p. 1311. ■ Report IV site burning and stinging promptly. ■ Drink at least 2 liters of fluid each day.

Maternal/Child:

Category D: avoid pregnancy; can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established.

Elderly:

May be more sensitive to toxic effects of the drug. Consider age-related organ impairment. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Potentiates **anticoagulants.** ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ **Cimetidine** (Tagamet), **interferon-alfa, and leucovorin calcium** may increase toxicity. ■ Additive bone marrow suppression may occur with **radiation therapy, other bone marrow–suppressing agents** (e.g., azathioprine, chloramphenicol, irinotecan, melphalan, vinorelbine), **and/or agents that cause blood dyscrasias** (e.g., metronidazole). ■ **Thiazide diuretics** (e.g., chlorothiazide) may prolong antineoplastic-induced leukopenia. ■ May decrease metabolism and increase serum levels of **phenytoin**.

SIDE EFFECTS

Abnormal bromsulphalein (BSP), prothrombin, total protein, sedimentation rate; alopecia (reversible), anaphylaxis, bleeding, bone marrow suppression (agranulocytosis, anemia, leukopenia, pancytopenia, thrombocytopenia), cerebellar syndrome, cramps, dermatitis, diarrhea, disorientation, dry lips, erythema, esophagopharyngitis and stomatitis (may lead to sloughing and ulceration), euphoria, frequent stools, GI ulceration and bleeding, headache, hemorrhage from any site, increased skin pigmentation, infection, lacrimal duct stenosis, mouth soreness and ulceration, myocardial ischemia, nail changes, nausea, palmar-plantar erythrodysesthesia syndrome (tingling of hands and feet followed by pain, redness, and swelling), photophobia, photosensitivity, pneumopathy (cough, shortness of breath), thrombophlebitis, visual changes, vomiting (intractable). Diarrhea and stomatitis are most common and may be more severe with a prolonged duration in patients on combination therapy. Pseudomembranous colitis has been reported.

ANTIDOTE

Keep physician informed of any side effects. Discontinue the drug and notify physician promptly at the first sign of toxicity (e.g., bleeding, diarrhea, esophagopharyngitis, gastritis, intractable vomiting, rapidly falling white count, sores in or around the lips or mouth, stomatitis). Nadir of leukocyte count occurs around Days 9 to 14. Recovery should be by Day 30. Discontinue the drug if the WBC count is less than 3,500/mm^3 or platelets are less than 100,000/mm^3; should reach 4,000/mm^3 and 130,000/mm^3 respectively in 2 weeks; if they do not, discontinue treatment. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes, and/or blood modifiers [e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim]) may be indicated to treat bone marrow toxicity. Continue to monitor for 4 weeks. Palmar-plantar erythrodysesthesia syndrome has been treated with oral pyridoxine (vitamin B_6), 100 to 150 mg daily. Death may occur from the progression of many side effects. There is no specific antidote; supportive therapy as indicated will help sustain the patient in toxicity.

FOLIC ACID

(**FOH**-lik **AS**-id)
Nutritional supplement (vitamin)
Antianemic
pH 8 to 11

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Therapeutic dose:

0.1 to 1 mg daily (never give less than 0.1 mg). Larger doses may be required.

Maintenance dose:

0.4 mg daily. ***Pregnant or lactating females:*** 0.8 mg daily.

PEDIATRIC DOSE

See Maternal/Child.

Therapeutic dose:

0.1 to 1 mg daily (never give less than 0.1 mg).

Maintenance dose:

Infants: 0.1 mg daily. ***Under 4 years of age:*** Up to 0.3 mg daily. ***Over 4 years of age:*** Same as adult.

DOSE ADJUSTMENTS

Increased initial and maintenance doses may be required in alcoholism, hemolytic anemia, anticonvulsant therapy, or chronic infection.

DILUTION

Each dose (up to 5 mg) should be diluted in at least 50 mL of SWFI, D5W, or NS. May be added to most IV solutions and given as an infusion.

Storage:

Protect from light and freezing.

COMPATIBILITY

Consider any drug NOT listed as compatible to be INCOMPATIBLE until consulting a pharmacist; specific conditions may apply.

Manufacturer lists as **incompatible** with calcium gluconate (even though a precipitate cannot be seen), doxapram, heavy metal ions, iron sulfate, oxidizing agents, reducing agents, solutions with a pH less than 5.

RATE OF ADMINISTRATION

Usually given over 30 minutes or more in an infusion.

ACTIONS

Folic acid is part of the vitamin B complex. In humans, exogenous folate is required for nucleoprotein synthesis and the maintenance of normal erythropoiesis. It is the precursor of tetrahydrofolic acid, an important cofactor involved in the synthesis of amino acids and DNA. Stimulates the production of RBCs, WBCs, and platelets. Metabolized in the liver and excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

For prevention and treatment of folic acid deficiency. Megaloblastic anemias resulting from folic acid deficiency may be seen in sprue; anemias of malnutrition, pregnancy, infancy, and childhood; developmental or surgical anomalies of the GI tract; and other conditions.

CONTRAINDICATIONS

Pernicious anemia unless used in combination with diagnostic testing.

PRECAUTIONS

Folic acid is not commonly administered by the IV route. Oral or IM administration provides adequate absorption in most cases. ■ Obscures the peripheral blood picture and prevents the diagnosis of pernicious anemia. May actually aggravate the neurologic symptoms.

Monitor:

Obtain CBC before and during therapy.

Maternal/Child:

Category A: an important vitamin before and during pregnancy. Folate-deficient mothers have a higher incidence of fetal anomalies and complications of pregnancy. ■ Safe for use during breast-feeding; infant may require supplementation if mother is folate deficient. ■ Some products contain benzyl alcohol as a preservative. Avoid use in neonates.

Elderly:

More likely to have folate deficiency.

DRUG/LAB INTERACTIONS

Toxic effects of antineoplastic folic acid antagonists are blocked by **folinic acid** (leucovorin calcium) but not by folic acid IV. ■ Increases **phenytoin** metabolism; seizures may result. ■ Inhibited by **dihydrofolate reductase inhibitors** (e.g., methotrexate, trimethoprim), **pyrimethamine, and triamterene** and by depressed **hematopoiesis, alcoholism,** and deficiencies of **vitamins B_6, B_{12}, C, and E.** ■ **Aminosalicylic acid** or **sulfasalazine** may decrease serum folate levels. ■ **Oral contraceptives** may inhibit folate metabolism.

SIDE EFFECTS

Almost nonexistent. Confusion, some slight flushing or feeling of warmth, nausea; anaphylaxis can occur.

ANTIDOTE

If anaphylaxis occurs, discontinue drug, treat anaphylaxis, and notify physician. Resuscitate as necessary.

FOMEPIZOLE INJECTION

(foh-**MEP**-ih-zoll in-**JEK**-shun)
Antizol
Antidote

USUAL DOSE

Begin fomepizole treatment immediately upon suspicion of ethylene glycol or methanol ingestion based on patient history and/or anion gap metabolic acidosis, increased osmolar gap, visual disturbances, or oxalate crystals in the urine, or a documented serum ethylene glycol or methanol concentration greater than 20 mg/dL. Ethylene glycol is the main component of antifreeze and coolants. Methanol is the main component of windshield washer fluid and a component of products such as Sternol (for fondue pots), Heet (gasoline antifreeze), and various paint products.

Adults with blood concentrations over 20 mg/dL but less than 50 mg/dL:

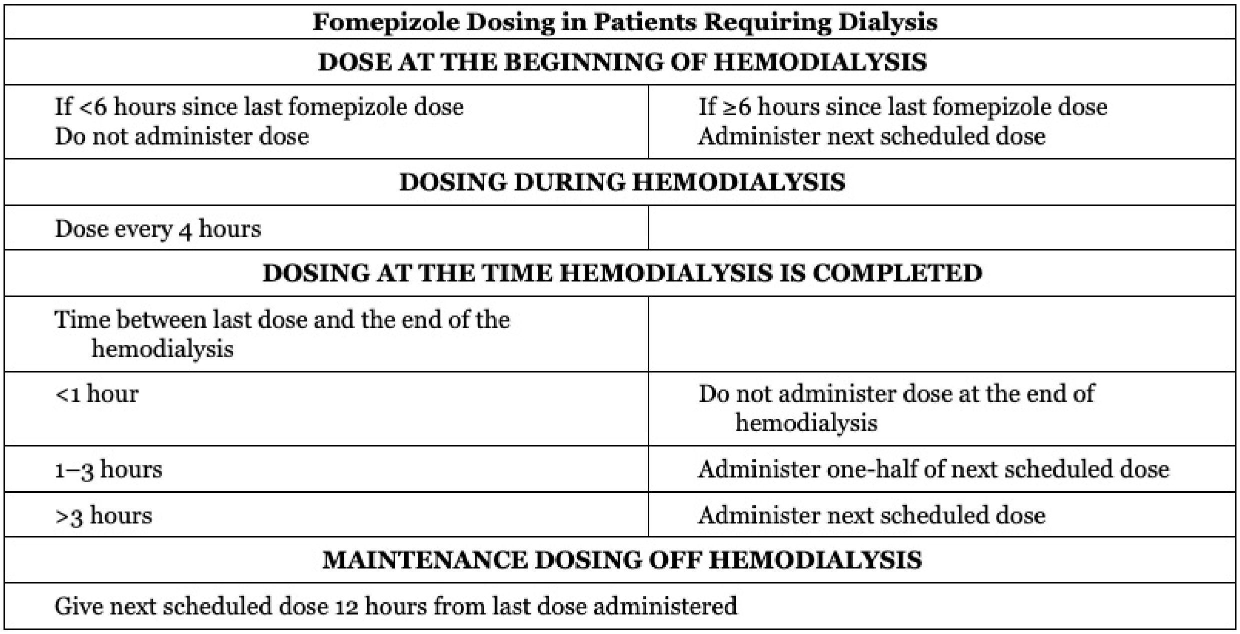
Administer a loading dose of 15 mg/kg as a slow intravenous infusion. Follow with 10 mg/kg every 12 hours times 4 doses, then 15 mg/kg every 12 hours until ethylene glycol or methanol concentrations are undetectable or have been reduced below 20 mg/dL and the patient is asymptomatic with normal pH.

Adults with blood concentrations of 50 mg/dL or higher, renal failure, or significant or worsening metabolic acidosis:

In addition to dosing as above, dialysis should be considered to correct metabolic abnormalities and to lower the ethylene glycol or methanol concentrations below 50 mg/dL.

Dosage with renal dialysis:

Amount of loading dose and following doses (mg/kg) remains the same, but fomepizole is dialyzable and the frequency of dosing should be increased to every 4 hours during hemodialysis. Base frequency on the following chart.



Fomepizole Dosing in Patients Requiring Dialysis	
DOSE AT THE BEGINNING OF HEMODIALYSIS	
If <6 hours since last fomepizole dose Do not administer dose	If ≥6 hours since last fomepizole dose Administer next scheduled dose
DOSING DURING HEMODIALYSIS	
Dose every 4 hours	
DOSING AT THE TIME HEMODIALYSIS IS COMPLETED	
Time between last dose and the end of the hemodialysis	
<1 hour	Do not administer dose at the end of hemodialysis
1–3 hours	Administer one-half of next scheduled dose
>3 hours	Administer next scheduled dose
MAINTENANCE DOSING OFF HEMODIALYSIS	
Give next scheduled dose 12 hours from last dose administered	

DOSE ADJUSTMENTS

Fomepizole has not been studied sufficiently to determine whether the pharmacokinetics differ for the elderly (see Elderly), pediatric patients, between genders, in renal insufficiency (excreted renally), or in hepatic insufficiency (metabolized by the liver).

DILUTION

Fomepizole solidifies at temperatures less than 25° C (77° F). If it is solidified, liquefy by running the vial under warm water or by holding in the hand. Solidification does not affect the efficacy, safety, or stability. Withdraw the appropriate dose. Each single dose ***must be diluted*** in at least 100 mL of NS or D5W and given as an infusion. Mix well.

Storage:

Store vials at CRT 20° to 25° C (68° to 77° F). Diluted solutions are stable refrigerated or at CRT for 48 hours; however, manufacturer states should be used within 24 hours of dilution.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each single dose must be given as a slow intravenous infusion equally distributed over 30 minutes. ***Do not give undiluted or by bolus injection;*** has caused serious venous irritation and phlebosclerosis.

ACTIONS

A synthetic competitive alcohol dehydrogenase inhibitor. Effectively blocks formation of toxic metabolites (glycolic and oxalic acids [ethylene glycol] and formic acid [methanol]). These toxins can induce metabolic acidosis, nausea and vomiting, seizures, stupor, coma, calcium oxaluria, acute tubular necrosis, blindness, and death. Has shown minimal CNS depressant effects. Plasma half-life varies with dose and has not been calculated. Rapidly distributes into total body water. Metabolized in the liver by the P_{450} mixed-function oxidase system. Significant increases in the elimination rate occur after 30 to 40 hours. Excreted in urine.

INDICATIONS AND USES

An antidote for ethylene glycol (antifreeze) or methanol (windshield wiper fluid) poisoning, or for use in suspected ethylene glycol or methanol ingestion either alone or in combination with hemodialysis.

CONTRAINDICATIONS

Known serious hypersensitivity to fomepizole or other pyrazoles (e.g., sulfinpyrazone).

PRECAUTIONS

Acute ethylene glycol or methanol poisoning is a medical emergency that is characterized by a syndrome that can include CNS depression, severe metabolic acidosis, renal failure, and coma. Can be lethal if left untreated or when treatment is delayed due to delayed diagnosis. The lethal dose of ethylene glycol is approximately 1.4 mL/kg. The lethal dose of methanol is approximately 1.2 mL/kg. ■ If ethylene glycol or methanol poisoning is left untreated, the natural progression of the poisoning leads to accumulation of toxic metabolites, including glycolic and oxalic acids (ethylene glycol) and formic acid (methanol). These metabolites can induce metabolic acidosis, nausea and vomiting, seizures, stupor, coma, calcium oxaluria, acute tubular necrosis, and death. ■ The diagnosis of these poisonings may be difficult because ethylene glycol and methanol levels diminish in the blood as they are metabolized. ■ The ethylene glycol or methanol concentrations and the acid-base balance, as determined by serum electrolyte (anion gap) and/or arterial blood gas analysis, should be frequently monitored and used to guide treatment. ■ Fomepizole has caused minor hypersensitivity reactions (mild rash, eosinophilia).

Monitor:

Maintain a patent airway and support ventilation as indicated; CNS and respiratory distress may occur suddenly. ■ Gastric lavage may be indicated if performed soon after ingestion or in patients who are comatose or at risk for seizures. ■ Patients must be managed for metabolic acidosis, acute renal failure (ethylene glycol), adult respiratory distress syndrome, visual disturbances (methanol), and hypocalcemia (may result in tetany). Sodium bicarbonate may be required to treat metabolic acidosis. Correct electrolyte imbalance and maintain adequate urine output with IV fluids. A decrease in the amount of fluids will be required in impending renal failure to prevent fluid overload; monitor closely. ■ Potassium supplementation and oxygen administration are usually necessary. ■ Administer IV calcium to patients with seizures or tetany that may be caused by decreased calcium, but do not attempt to correct hypocalcemia itself (may increase precipitation of calcium oxalate crystals in the tissues). ■ Hemodialysis is necessary in the anuric patient and should be considered in patients with severe metabolic acidosis or azotemia and in any patient with high ethylene glycol or methanol concentrations (equal to or greater than 50 mg/dL). ■ ECG should be continuous to monitor for cardiac irregularities. ■ EEG may be required in the comatose patient. ■ The effective inhibition of alcohol dehydrogenase requires fomepizole plasma concentrations in the range of 100 to 300 micromol/L (8.6 to 24.6 mg/L). ■ To assess treatment success, obtain baseline and frequently monitor measurements of blood gases, pH, electrolytes, BUN, creatinine, and urinalysis in addition to other laboratory tests as indicated by each patient's condition. ■ To assess the status of ethylene glycol or methanol and their respective metabolite clearances, obtain baseline ethylene glycol or methanol plasma and urine concentrations and presence of urinary oxalate crystals (ethylene glycol) and monitor frequently. ■ Obtain baseline and monitor hepatic enzymes and WBC counts during treatment; transient increases in serum transaminase levels and eosinophilia have been noted with repeated fomepizole dosing. ■ Monitor for signs of hypersensitivity reactions; see Precautions.

Patient Education:

Monitoring of urine output imperative. ■ Cooperation with adequate hydration and frequent laboratory analysis required. ■ Request assistance with ambulation.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Decreased testicular mass in rats. ■ Use caution during breast-feeding; not known if fomepizole is secreted in breast milk. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Risk of toxic reactions may be greater in patients with impaired renal function; consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Has not been studied, but reciprocal interactions (increasing or decreasing clearance, effects, or toxicity) may occur with concomitant use of **drugs that induce or inhibit the cytochrome P_{450} system**. Ethanol decreased the rate of elimination of fomepizole (by 50%).

SIDE EFFECTS

The most common side effects are dizziness, headache, and nausea. Abdominal pain, abnormal smell, anemia, anorexia, arrhythmias (bradycardia, tachycardia), back pain (lower), blurred vision, decreased awareness of surroundings, diarrhea, DIC, feeling of drunkenness, fever, hangover, heartburn, hiccups, hypersensitivity reactions (e.g., mild rash, eosinophilia), hypotension, injection site reaction, light-headedness, lymphangitis, multisystem organ failure, nystagmus, pharyngitis, phlebitis, phlebosclerosis, seizure, shock, slurred speech, somnolence, taste changes (bad or metallic), vertigo, visual problems, vomiting occurred in up to 6% of patients.

Overdose:

Dizziness, nausea, and vertigo occurred in healthy volunteers given 3 to 6 times the recommended dose.

ANTIDOTE

Keep physician informed of all side effects, laboratory results, and concurrent medical problems. Dialysis may be indicated for changes in patient condition (e.g., renal failure, significant or worsening metabolic acidosis, or a measured ethylene glycol or methanol concentration of greater than 50 mg/dL) or in the treatment of overdose. Treat side effects symptomatically as indicated. Resuscitate as necessary.

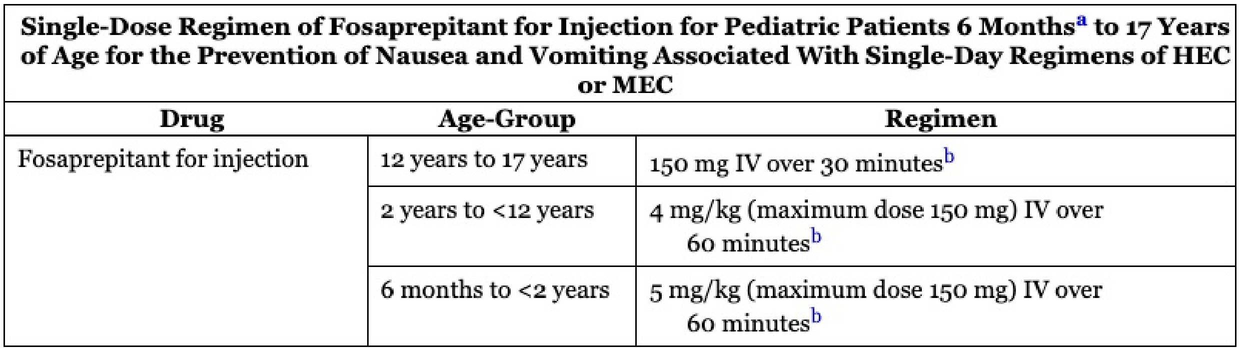
FOSAPREPITANT DIMEGLUMINE

(fos-ap-**RE**-pi-tant dye-**MEG**-loo-meen)
Emend
Antiemetic Substance P/NK$_1$ receptor antagonist

USUAL DOSE

150 mg as IV infusion over 20 to 30 minutes, completing the infusion approximately 30 minutes before chemotherapy. Given in combination with dexamethasone and a 5-HT$_3$ antagonist.

PEDIATRIC DOSE

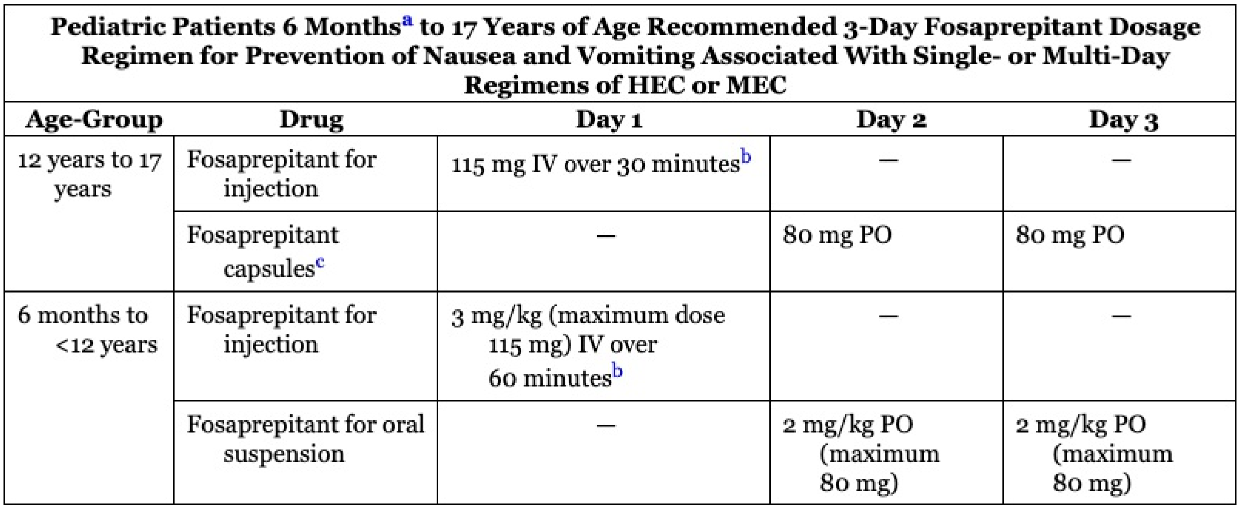


Single-Dose Regimen of Fosaprepitant for Injection for Pediatric Patients 6 Months[a] to 17 Years of Age for the Prevention of Nausea and Vomiting Associated With Single-Day Regimens of HEC or MEC

Drug	Age-Group	Regimen
Fosaprepitant for injection	12 years to 17 years	150 mg IV over 30 minutes[b]
	2 years to <12 years	4 mg/kg (maximum dose 150 mg) IV over 60 minutes[b]
	6 months to <2 years	5 mg/kg (maximum dose 150 mg) IV over 60 minutes[b]

[a] Dosing in pediatric patients less than 6 kg is not recommended.

[b] Complete fosaprepitant infusion on Day 1 approximately 30 minutes before chemotherapy.



Pediatric Patients 6 Months[a] to 17 Years of Age Recommended 3-Day Fosaprepitant Dosage Regimen for Prevention of Nausea and Vomiting Associated With Single- or Multi-Day Regimens of HEC or MEC

Age-Group	Drug	Day 1	Day 2	Day 3
12 years to 17 years	Fosaprepitant for injection	115 mg IV over 30 minutes[b]	—	—
	Fosaprepitant capsules[c]	—	80 mg PO	80 mg PO
6 months to <12 years	Fosaprepitant for injection	3 mg/kg (maximum dose 115 mg) IV over 60 minutes[b]	—	—
	Fosaprepitant for oral suspension	—	2 mg/kg PO (maximum 80 mg)	2 mg/kg PO (maximum 80 mg)

[a] Dosing in pediatric patients less than 6 kg is not recommended.

[b] Complete fosaprepitant infusion approximately 30 minutes before chemotherapy.

[c] For patients 12 years to 17 years of age who cannot swallow oral capsules, fosaprepitant for oral suspension can be used instead.

DOSE ADJUSTMENTS

No dose adjustment indicated based on race, gender, body mass index (BMI), renal status (including patients with ESRD on dialysis), or mild to moderate hepatic insufficiency. Data in patients with severe hepatic insufficiency (Child-Pugh score >9) not available.

DILUTION

Reconstitute each 150-mg vial with 5 mL of NS. Direct stream of NS to side of vial to avoid foaming. Swirl gently; do not shake. Prepare an infusion bag with 145 mL of NS. Withdraw entire volume of reconstituted vial and transfer it into the infusion bag. Gently invert the bag 2 to 3 times. Final concentration is 1 mg/mL. Determine the volume to be administered from the prepared infusion bag based on the recommended dose.

Adults:

The entire volume of the prepared infusion bag (150 mL) should be administered.

Pediatric patients 12 years of age and older:

The volume to be administered is calculated as follows:

Volume to administer (mL) = Recommended dose (mg)

Pediatric patients 6 months to less than 12 years of age:

The volume to be administered is calculated as follows:

Volume to administer (mL) = Recommended dose (mg/kg) × weight (kg)

Note: Do not exceed the maximum dose

In pediatric patients, the entire volume in the infusion bag may not be required. If necessary, for volumes less than 150 mL, the calculated volume can be transferred to an appropriate-size bag or syringe before administration by infusion.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). Diluted solution is stable for 24 hours at RT.

COMPATIBILITY

Manufacturer states, “Do not mix or reconstitute with solutions for which physical and chemical **compatibility** have not been established. Fosaprepitant (Emend) for injection is **incompatible** with any solutions containing divalent cations (e.g., calcium or magnesium), including lactated Ringer’s solution and Hartmann’s solution.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adults:

A single dose as an infusion equally distributed over 20 to 30 minutes.

Pediatric patients 12 to 17 years of age:

A single dose as an infusion through a central venous catheter over 30 minutes.

Pediatric patients 6 months to less than 12 years of age:

A single dose as an infusion through a central venous catheter over 60 minutes.

ACTIONS

A prodrug of aprepitant, a substance P/neurokinin$_1$ (NK$_1$) receptor antagonist. Has little or no affinity for 5-HT$_3$, dopamine, and corticosteroid receptors (the targets of existing therapies for chemotherapy-induced nausea and vomiting). Fosaprepitant is rapidly converted to aprepitant following IV administration. Aprepitant inhibits emesis induced by cytotoxic chemotherapeutic agents, such as cisplatin, via central actions. Crosses the blood-brain barrier and occupies brain NK$_1$ receptors. Augments the antiemetic activity of the 5-HT$_3$-receptor antagonist ondansetron and the corticosteroid dexamethasone and inhibits both the acute and delayed phases of cisplatin-induced emesis. Highly protein bound. Undergoes extensive metabolism, primarily by CYP3A4 and to a lesser extent by CYP1A2 and CYP2C19. Eliminated primarily by metabolism; not renally excreted. Half-life is approximately 9 to 13 hours.

INDICATIONS AND USES

Given in combination with other antiemetics in adult and pediatric patients 6 months of age and older for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of highly emetogenic cancer chemotherapy, including high-dose cisplatin and delayed nausea and vomiting associated with initial and repeat courses of moderately emetogenic cancer chemotherapy.

Limitation of use:

Has not been studied for treatment of established nausea and vomiting.

CONTRAINDICATIONS

Hypersensitivity to fosaprepitant or any components of the product. ■ Concurrent use with pimozide; see Drug Interactions.

PRECAUTIONS

Fosaprepitant is rapidly converted to aprepitant, which is a substrate, inhibitor, and inducer of CYP3A4. Use with caution in patients receiving concomitant medications that are primarily metabolized through CYP3A4; see Drug Interactions. ■ Use with caution in patients with severe hepatic insufficiency (Child-Pugh score >9); see Dose Adjustments. ■ Serious hypersensitivity reactions, including anaphylaxis and anaphylactic shock, during or soon after infusion have been observed; see Monitor. ■ Infusion site reactions (ISR) have been reported. The majority of severe ISRs (e.g., thrombophlebitis, vasculitis) have been reported with concomitant vesicant (anthracycline-based) chemotherapy administration, particularly when associated with extravasation. Necrosis was also reported with concomitant vesicant chemotherapy. Most ISRs occurred with the first, second, or third exposure to single doses of fosaprepitant, and in some cases reactions lasted for up to 2 weeks. Avoid infusion of fosaprepitant for injection into small veins or through a butterfly catheter; see Monitor and Drug/Lab Interactions.

Monitor:

Monitor for S/S of hypersensitivity reactions during and after the infusion (e.g., anaphylaxis, anaphylactic shock, dyspnea, erythema, flushing, hypotension, and syncope). ■ Monitor IV site for reactions. ■ See Drug/Lab Interactions.

Patient Education:

Read manufacturer-supplied patient package insert before starting therapy. ■ Discontinue use of fosaprepitant and promptly report S/S of a hypersensitivity reaction (e.g., difficulty breathing or swallowing, dizziness, feeling faint, flushing, hives, itching, rapid or weak heartbeat, rash, skin peeling, or sores). ■ Efficacy of hormonal contraceptives may be reduced during and for 28 days following administration of the last dose of fosaprepitant; includes birth control pills, skin patches, implants, and certain IUDs. Alternative or backup methods of contraception should be used during treatment and for 1 month following the last dose of fosaprepitant. ■ Numerous drug interactions possible. A complete review of all prescription, nonprescription, and herbal products is required before each dose. ■ Patients on chronic warfarin therapy should have their INR checked in the 2-week period, particularly at 7 to 10 days, following initiation of fosaprepitant with each chemotherapy cycle. ■ Report new or worsening infusion site reactions (e.g., edema, erythema, necrosis, pain, thrombophlebitis, or vasculitis).

Maternal/Child:

Should be used during pregnancy only if clearly needed. ■ Information on use during breast-feeding not available. Use caution. ■ Safety and effectiveness of a single-dose regimen and a 3-day IV/oral regimen of fosaprepitant have been established for use in pediatric patients 6 months to 17 years of age for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of HEC and MEC. ■ Safety and effectiveness of fosaprepitant injection administered on consecutive days has not been established in pediatric patients 6 months to 17 years of age for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of HEC and MEC. ■ Safety and effectiveness for the prevention of nausea and vomiting associated with HEC or MEC have not been established in patients under 6 months of age.

Elderly:

Response similar to that seen in younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Fosaprepitant is rapidly converted to aprepitant. When given as a single 150-mg dose, it is a **weak inhibitor of CYP3A4,** and the weak inhibition of CYP3A4 continues for 2 days after the single dose. Single-dose fosaprepitant does not induce CYP3A4. **Aprepitant is a substrate, inhibitor, and inducer of CYP3A4. It is also an inducer of CYP2C9.** ■ Efficacy of **hormonal contraceptives** may be reduced during and for 28 days following administration of the last dose of fosaprepitant or aprepitant; see Patient Education. ■ Patients on chronic **warfarin** therapy should be closely monitored over a 2-week period, particularly at 7 to 10 days following initiation of fosaprepitant with each chemotherapy cycle. Coadministration may result in a clinically significant decrease in INR. ■ Concurrent use with **pimozide** is ***contraindicated.*** Inhibition of CYP3A4 by fosaprepitant or aprepitant could result in elevated plasma concentrations of pimozide, potentially causing serious or life-threatening reactions, including prolongation of the QT interval; see Contraindications. ■ Fosaprepitant/aprepitant can increase plasma concentrations of **dexamethasone and methylprednisolone**. When given concurrently with fosaprepitant or aprepitant, reduce the dexamethasone and methylprednisolone PO doses by approximately 50% and the methylprednisolone IV dose by approximately 25%. (Dexamethasone doses listed in Usual Dose take drug interaction into account.) ■ Coadministration of fosaprepitant or aprepitant with **chemotherapy agents metabolized by CYP3A4** (e.g., irinotecan, ifosfamide, imatinib, vinblastine, and vincristine) should be done with caution and careful monitoring. In clinical studies, the oral aprepitant regimen was commonly administered with etoposide, vinorelbine, paclitaxel, and docetaxel. Dose adjustments were not required. ■ May increase plasma levels of **benzodiazepines** (e.g., alprazolam, midazolam). Monitor for sedation or other benzodiazepine-related adverse reactions. ■ Aprepitant is a CYP2C9 inducer. Has been shown to induce metabolism of **CYP2C9 substrates** (e.g., phenytoin, tolbutamide, warfarin), thus decreasing plasma concentrations. Monitor patients receiving CYP2C9 substrates as indicated (e.g., plasma drug concentrations, therapeutic effect/efficacy, blood sugar control). ■ Concurrent use with **CYP3A4 inhibitors** (e.g., clarithromycin, diltiazem, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir) may increase aprepitant or fosaprepitant plasma concentrations and increase the risk of adverse reactions. Use caution. ■ Coadministration with **CYP3A4 inducers** (e.g., carbamazepine, phenytoin, rifampin) may decrease fosaprepitant or aprepitant plasma concentrations and decrease efficacy. ■ Aprepitant is a moderate **inhibitor of CYP3A4**. Use with caution in patients receiving concomitant medications that are primarily metabolized through CYP3A4.

SIDE EFFECTS

Adults:

The most common side effects reported include anemia, asthenia, diarrhea, dyspepsia, fatigue, neutropenia, pain in extremity, peripheral neuropathy, and urinary tract infections. Other reported side effects include infusion site reactions (e.g., erythema, induration, pain, pruritus, infusion site thrombophlebitis).

Pediatric patients:

Adverse reactions in pediatric patients are similar to those for adults. In pediatric patients (6 months to 17 years) the most common side effects were anemia, febrile neutropenia, neutropenia, and thrombocytopenia.

Post-Marketing:

Hypersensitivity reactions (including anaphylaxis and anaphylactic shock), pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria have been reported. Ifosfamide-induced neurotoxicity after fosaprepitant and ifosfamide coadministration have also been reported.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue fosaprepitant at the first sign of hypersensitivity. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone), and pressor amines (e.g., dopamine). Do not reinitiate therapy in patients who have had a previous hypersensitivity reaction. Discontinue fosaprepitant for a severe ISR. Treatment for a severe ISR consists of medical and possibly surgical intervention. In the event of overdose, discontinue treatment and provide general supportive treatment and monitoring. Because of the antiemetic activity of fosaprepitant, drug-induced emesis may not be effective in cases of overdose. Fosaprepitant is not removed by hemodialysis.

FOSCARNET SODIUM BBW

(fos-**KAR**-net **SO**-dee-um)
Foscavir
Antiviral
pH 7.4

USUAL DOSE

Pretreatment:

Baseline studies indicated. Adequate hydration and other specific testing required; see Monitor.

An individualized dose should be calculated based on body weight (mg/kg), renal function, indication of use, and dosing frequency. To reduce the risk of nephrotoxicity, creatinine clearance (mL/min/kg) should be calculated even if SCr is within the normal range.

CMV retinitis:

90 mg/kg every 12 hours or 60 mg/kg every 8 hours for 14 to 21 days. Length of induction treatment based on clinical response. Begin a maintenance dose of 90 mg/kg/day the next day (Day 15 to 22). If retinitis progresses during the maintenance regimen, retreat with the induction and maintenance regimens. Maintenance dose may be increased to 120 mg/kg/day in patients who show excellent tolerance to foscarnet or those who require early re-induction because of retinitis progression. Normal renal function required. Patients who experience a progression of retinitis while receiving foscarnet maintenance therapy may be retreated with the induction and maintenance regimens listed previously or with a combination of foscarnet and ganciclovir. See the Clinical Trials section in the foscarnet sodium prescribing information.

Acyclovir-resistant HSV patients:

40 mg/kg every 8 or 12 hours for 2 to 3 weeks or until healed.

DOSE ADJUSTMENTS

Foscarnet is not recommended in patients undergoing hemodialysis because dosage guidelines have not been established.

Dose must be individualized according to patient’s renal function. Safety and efficacy data for patients with baseline SCr greater than 2.8 mg/dL or measured 24-hour CrCl less than 50 mL/min are limited. Dose adjustment may be required during treatment even if the patient had normal renal function initially. Recommended doses based on renal function are listed in the following charts. To use these dosing guides, the actual 24-hour CrCl (mL/min) must be divided by body weight (kg), or the estimated CrCl in mL/min/kg can be calculated from the SCr (mg/dL) using the following formula (modified Cockcroft-Gault equation):

$$\text{For males: CrCl (mL/min/kg)} = (140 - \text{Age}) \div (\text{SCr} \times 72)$$

$$\text{For females: CrCl (mL/min/kg)} = [(140 - \text{Age}) \div (\text{SCr} \times 72)] \times 0.85$$

Foscarnet Dose Adjustment Guide for Induction				
	Acyclovir-Resistant HSV		**CMV Retinitis**	
CrCl (mL/min/kg)	**Dose of 40 mg/kg q 12 hr**	**Dose of 40 mg/kg q 8 hr**	**Dose of 60 mg/kg q 8 hr**	**Dose of 90 mg/kg q 12 hr**
>1.4 mL/min/kg	40 mg/kg q 12 hr	40 mg/kg q 8 hr	60 mg/kg q 8 hr	90 mg/kg q 12 hr
>1–1.4 mL/min/kg	30 mg/kg q 12 hr	30 mg/kg q 8 hr	45 mg/kg q 8 hr	70 mg/kg q 12 hr
>0.8–1 mL/min/kg	20 mg/kg q 12 hr	35 mg/kg q 12 hr	50 mg/kg q 12 hr	50 mg/kg q 12 hr

<0.4 mL/min/kg	Not recommended	Not recommended

DILUTION

Available in a single-use, 250-mL glass bottle containing 6,000 mg of foscarnet (24 mg/mL). An individualized dose at the required concentration (24 mg/mL or 12 mg/mL) for the route administration (central line or peripheral line) must be aseptically prepared before dispensing. Remove any excess quantity of medication from the infusion bottle using aseptic technique. To avoid any possibility of overdose, only the calculated dose should be in the infusion bottle. Discard any excess before administration.

Central line:

Standard 24-mg/mL solution may be given undiluted.

Peripheral line:

Each 1 mL of a calculated dose must be diluted with 1 mL of D5W or NS (yields a 12-mg/mL solution).

Storage:

Store at CRT. Avoid excessive heat and freezing. Use only if vacuum is present and solution is clear and colorless. Use solution within 24 hours of entry into bottle.

COMPATIBILITY

Manufacturer states, “Administer only with NS or D5W solutions; no other drug or supplement should be administered concurrently via the same catheter.” Because of chelating properties, a precipitate can occur. Manufacturer specifically lists as **incompatible** with 30% dextrose, solutions containing calcium (e.g., LR, TPN), acyclovir, amphotericin B, diazepam, digoxin, ganciclovir, leucovorin calcium, midazolam, pentamidine, phenytoin, prochlorperazine, sulfamethoxazole/trimethoprim, trimetrexate glucuronate, vancomycin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not administer by rapid or bolus IV injection. Infusion pump required to deliver accurate dose evenly distributed over specific time frame. Excessive plasma levels and toxicity (including a decrease in ionized calcium) will occur with too-rapid rate of infusion. Slowing the infusion rate may decrease or prevent symptoms. Advisable to clear tubing with NS if possible before and after administration through Y-tube or three-way stopcock. Never exceed 1 mg/kg/min.

CMV retinitis:

Induction doses:

Each 60-mg/kg dose equally distributed over a minimum of 1 hour. Increase to 1½ to 2 hours for 90-mg/kg dose.

Maintenance dose:

Each dose equally distributed over a minimum of 2 hours.

Acyclovir-resistant HSV:

Each dose equally distributed over a minimum of 1 hour.

ACTIONS

An antiviral agent capable of inhibiting replication of herpes viruses, including cytomegalovirus (CMV), herpes simplex virus types 1 and 2 (HSV-1, HSV-2), and varicella zoster virus (VZV [unlabeled]). Does not destroy existing viruses but stops them from reproducing and invading healthy cells. Also capable of chelating metal ions (e.g., calcium, magnesium). CMV strains resistant to ganciclovir and HSV strains resistant to acyclovir may be sensitive to foscarnet. Some penetration into bone and cerebrospinal fluid. Plasma half-life ranges from 2 to 6 hours and increases markedly with renal impairment. Terminal half-life determined by urinary excretion was 87.5 +/− 41.8 hours, possibly due to release of foscarnet from bone. Excreted unchanged in urine.

INDICATIONS AND USES

Treatment of CMV retinitis in patients with AIDS. Most frequently used in patients who do not tolerate or are resistant to ganciclovir. Combination therapy with ganciclovir is indicated for patients who have relapsed after monotherapy with either drug. ■ Treatment of acyclovir-resistant mucocutaneous HSV infections in immunocompromised patients.

CONTRAINDICATIONS

Hypersensitivity to foscarnet.

PRECAUTIONS

For IV use only. ■ Safety and efficacy of foscarnet have not been established for treatment of other CMV infections (e.g., pneumonitis, gastroenteritis), congenital or neonatal CMV disease, other HSV infections (e.g., retinitis, encephalitis), congenital or neonatal HSV disease, or CMV or HSV in nonimmunocompromised individuals. Use should be limited to treatment of conditions listed in Indications and Uses above. ■ Renal impairment is the major toxicity of foscarnet. Frequent monitoring of serum creatinine, with dose adjustment for changes in renal function, and adequate hydration are imperative. Changes can occur at any time, most likely during second week of induction therapy. Elevations in SCr are usually reversible following dose adjustment or discontinuation of therapy. ■ Use caution in patients with a history of impaired renal function, altered calcium or other electrolyte levels, or neurologic or cardiac abnormalities and in patients receiving other drugs known to influence minerals and electrolytes; see Drug/Lab Interactions. Has caused hyperphosphatemia, hypocalcemia (and decreased ionized calcium, which may not be reflected in the total serum calcium), hypokalemia, hypomagnesemia, and hypophosphatemia, resulting in cardiac disturbances, seizures, and tetany. ■ Seizures related to alterations in plasma minerals and electrolytes have been reported and have included cases of status epilepticus. Several cases were associated with death. Risk factors for seizures included impaired baseline renal function, low total serum calcium, and underlying CNS conditions. ■ Serious acute hypersensitivity reactions have been reported. If an acute hypersensitivity reaction occurs, discontinue therapy and treat as indicated; see Antidote. ■ Foscarnet has been associated with prolongation of the QT interval. Use with caution in patients who have a history of QT prolongation, in patients taking medication known to prolong the QT interval, in patients with electrolyte disturbances, or in patients who have other risk factors for QT prolongation; see Drug Interactions. ■ Contains 5.5 mg sodium/mL. Avoid use in patients who may not tolerate a large amount of sodium or water (e.g., patients with cardiomyopathy) or in patients on a controlled-sodium diet. ■ In controlled clinical trials, anemia was reported in 33% of patients receiving foscarnet. Granulocytopenia was reported in 17% of patients. ■ Resistance has been reported to develop. May be higher in patients treated for a prolonged period. Consider the possibility of resistance in patients who show poor clinical response. ■ Amino acid substitutions conferring foscarnet resistance with cross-resistance to ganciclovir, cidofovir, and acyclovir have been identified. ■ Sensitivity testing of the viral isolate is recommended before repeat treatment and/or to evaluate sensitivity versus development of resistance.

Monitor:

Obtain baseline ECG, SCr, and CrCl (either 24-hour measurement or estimated using the modified Cockcroft-Gault equation based on serum creatinine). Baseline calcium, magnesium, potassium, phosphorus, and electrolytes required before treatment begins. Correct any deficiencies. ■ Repeat entire testing process 2 to 3 times a week during induction therapy and weekly during maintenance therapy. Foscarnet dose must be adjusted as indicated by test results. More frequent testing may be indicated in specific patients. Supplementation of minerals and electrolytes may be required during treatment. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylactic shock, angioedema, urticaria). ■ To minimize renal toxicity, hydration adequate to establish diuresis is recommended before and during treatment. Clinically dehydrated patients should be adequately hydrated before initiating therapy. Give 750 to 1,000 mL NS or D5W before the first foscarnet infusion to establish diuresis. With subsequent infusions, give 750 to 1,000 mL concurrently with 90 to 120 mg/kg foscarnet and a minimum of 500 mL concurrently with 40 to 60 mg/kg. Oral rehydration may be considered in certain patients. Hydration fluid may need to be decreased if clinically warranted. ■ Discontinue foscarnet if CrCl drops below 0.4 mL/min/kg. Monitor patient daily until resolution of renal impairment is ensured. Safety for use in these patients has not been studied. ■ Phlebitis or pain may occur at site of infusion; confirm patency of vein and use large veins to ensure adequate blood flow for rapid dilution and distribution. ■ See Drug/Lab Interactions.

Patient Education:

Not a cure. ■ Retinitis may progress during or after treatment; regular ophthalmologic exams imperative. ■ Complete healing of HSV infections may occur, but most relapse. ■ Perioral tingling, numbness in the extremities, or paresthesias indicate electrolyte abnormalities; report immediately. ■ Close monitoring of renal function and electrolyte balance during treatment is imperative. Hydration may help minimize the risk of renal toxicity. ■ Promptly report any cardiac symptoms (e.g., transient chest pain). ■ Cases of male and female genital irritation/ulceration have been reported. Adequate hydration and increased personal hygiene may minimize some side effects. ■ May cause CNS side effects (e.g., dizziness, seizures, somnolence) that could result in impairment. Use caution when driving or operating machinery. ■ Dose modification or discontinuation may be required for major side effects.

Maternal/Child:

Use only if clearly needed; has caused skeletal anomalies in animals. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established; deposited in teeth and bones, and deposition greater in young animals. Use only if benefits outweigh risks.

Elderly:

Safety and effectiveness not established; however, foscarnet has been used in patients over 65 years of age. Side effects seen are similar to other age-groups. Consider age-related renal impairment in dose selection, and monitor renal function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Because of physical **incompatibilities,** foscarnet sodium and **ganciclovir sodium** must never be mixed. ■ Has caused hypocalcemia with parenteral **pentamidine;** deaths have been reported. ■ Capable of causing calcium or electrolyte disorders. Use particular caution when administering **any drug known to influence serum calcium concentrations, other minerals, or electrolytes** (e.g., hypocalcemic agents [gallium nitrate], diuretics [furosemide, mannitol], adrenocortical steroids). ■ Elimination of foscarnet may be impaired and toxicity increased by **drugs that inhibit renal tubular secretion.** When **diuretics** are indicated, **thiazides** (e.g., hydrochlorothiazide) are recommended over **loop diuretics** (e.g., furosemide) because the latter inhibit renal tubular secretion. ■ Avoid concomitant use with other **nephrotoxic drugs** (e.g., acyclovir, aminoglycosides [e.g., gentamicin], amphotericin B, cyclosporine, methotrexate, pentamidine, tacrolimus) unless benefits outweigh risks. ■ Abnormal renal function has been reported in patients receiving foscarnet and **ritonavir** or foscarnet and **ritonavir and saquinavir**. ■ There is no clinically significant interaction with zidovudine or probenecid. ■ The combination antiviral activity of foscarnet and **ganciclovir** or **acyclovir** is not antagonistic in cell culture. ■ Foscarnet sodium should be avoided in combination with **agents known to prolong the QT interval**, including **Class IA antiarrhythmic agents** (e.g., procainamide or quinidine) or **Class III antiarrhythmic agents** (e.g., amiodarone, dofetilide, sotalol), **phenothiazines** (e.g., chlorpromazine), **tricyclic antidepressants** (e.g., amitriptyline), and certain **macrolide** (e.g., erythromycin) **and fluoroquinolone** (e.g., levofloxacin) **antibiotics**.

SIDE EFFECTS

Impaired renal function, alterations in plasma minerals and electrolytes, and seizures are major side effects and are dose limiting. Abnormal renal function, including acute renal failure, decreased CrCl, and increased SCr; anemia; bone marrow suppression; diarrhea; fatigue; fever; headache; hyperphosphatemia; hypocalcemia (perioral tingling, numbness in extremities, paresthesias, tetany); hypokalemia; hypomagnesemia; hypophosphatemia; irritation at injection site; irritation and ulcerations of penile and vaginal epithelium; nausea; rigors; seizure; vomiting; and death have occurred. All deaths could not be directly related to foscarnet. Abdominal pain, anorexia, anxiety, asthenia, confusion, coughing, depression, dizziness, dyspnea, granulocytopenia, hypoesthesia, infection, involuntary muscle contractions, leukopenia, malaise, neuropathy, pain, rash, sweating, and vision abnormalities have occurred in 5% of patients. Numerous other side effects have occurred in fewer than 5% of patients.

Post-Marketing:

Administration site extravasation, crystal-induced nephropathy, diabetes insipidus, esophageal ulcerations, Fanconi syndrome (acquired), gastrointestinal hemorrhage, glomerulonephritis, hypersensitivity reactions (serious, acute, including anaphylactic shock, angioedema, and urticaria), increased lipase, localized edema, muscle disorders (e.g., myopathy, myositis, muscle weakness, rhabdomyolysis), nephrotic syndrome, prolongation of the QT interval, proteinuria, renal calculi, renal tubular acidosis, renal tubular necrosis, status epilepticus, torsades de pointes, ventricular arrhythmia, vesiculobullous eruptions (e.g., erythema multiforme, toxic epidermal necrolysis, Stevens-Johnson syndrome).

ANTIDOTE

There is no specific antidote. Keep physician informed. Adequate hydration and careful monitoring will help reduce potential for renal impairment and may minimize other side effects. Elevations in SCr are usually reversible (within 1 week) with dose adjustment or discontinuation but have caused death. Discontinue foscarnet if CrCl falls below 0.4 mL/min/kg. Monitor daily until resolution of renal impairment is ensured. Discontinue foscarnet if perioral tingling, numbness in the extremities, or paresthesias occur during or after infusion; evaluate calcium and electrolyte levels (decrease in ionized serum calcium may not be reflected in total serum calcium); notify physician. Administration of foscarnet can be resumed following seizures or cardiac disturbances after treatment of underlying disease, electrolyte disturbance, or after dose adjustment. Overdose/toxicity can occur with too-rapid rate of infusion. Hemodialysis and hydration may be useful in overdose. Discontinue the infusion if an acute hypersensitivity reaction occurs. Treat immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

FOSNETUPITANT AND PALONOSETRON

(fos-net-**UE**-pi-tant and pal-oh-**NOE**-se-tron)
Akynzeo
Antiemetic
(Substance P/NK-1 receptor antagonist/
5-HT$_3$ receptor antagonist)

USUAL DOSE

Pretreatment:

See Maternal/Child.

Highly emetogenic chemotherapy, including cisplatin-based chemotherapy:

Administer 1 vial (235 mg fosnetupitant/0.25 mg palonosetron) as an IV infusion over 30 minutes starting 30 minutes before chemotherapy on Day 1. Administer 12 mg dexamethasone 30 minutes before chemotherapy on Day 1 and dexamethasone 8 mg once daily on Days 2 through 4.

The oral formulation of fosnetupitant/palonosetron may be substituted for the IV formulation and is also indicated for anthracyclines and cyclophosphamide-based chemotherapy and chemotherapy not considered highly emetogenic; see Limitation of Use.

DOSE ADJUSTMENTS

No dose adjustment necessary for patients with mild to moderate hepatic impairment (Child-Pugh score 5 to 8) or mild to moderate renal impairment (CrCl of 30 to 60 mL/min). Avoid use in patients with severe hepatic or renal impairment or end-stage renal disease.

DILUTION

Available as 235 mg fosnetupitant/0.25 mg palonosetron lyophilized powder in a single-dose vial for reconstitution. Inject 20 mL of D5W or NS into the vial, directing the stream along the vial wall to prevent foaming. Swirl vial gently. Prepare an infusion vial or bag filled with 30 mL of D5W or NS. Withdraw the entire contents of the reconstituted solution and transfer it into the infusion vial or bag containing 30 mL of D5W or NS to yield a total volume of 50 mL. Gently invert the vial or bag until completely dissolved. Discard if particulates and/or discoloration are observed.

Filter:

Data not available.

Storage:

Before use, refrigerate at 2° to 8° C (35.6° to 46.4° F) in carton to protect from light. Store reconstituted solution and the final diluted solution at RT. The total time from reconstitution to the start of infusion should not exceed 3 hours.

COMPATIBILITY

Manufacturer states, “Fosnetupitant/palonosetron is **incompatible** with any solution containing divalent cations (e.g., calcium, magnesium), including LR and Hartmann’s solution.”

Limited data are available on the **compatibility** of fosnetupitant and palonosetron with other IV substances, additives, or other medications, and they should not be added to the fosnetupitant and palonosetron solution or infused simultaneously. If the same IV line is used for sequential infusion of several different drugs, flush the line before and after infusion of fosnetupitant and palonosetron with NS.

RATE OF ADMINISTRATION

Administer over 30 minutes as an IV infusion. At the end of the infusion, flush the infusion line with the same carrier solution to ensure complete drug administration.

ACTIONS

Akynzeo for injection is a combination product of fosnetupitant, a prodrug of netupitant (a substance P/neurokinin 1 [NK-1] receptor antagonist), and palonosetron hydrochloride, a serotonin-3 (5-HT_3) receptor antagonist. Both are antinausea and antiemetic agents. Palonosetron prevents nausea and vomiting during the acute phase, and fosnetupitant prevents nausea and vomiting during both the acute and delayed phase after cancer chemotherapy. Palonosetron has a strong binding affinity for the 5-HT_3 receptor and little or no affinity for other receptors. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing serotonin receptors both on the vagus nerve in the periphery and centrally in the chemoreceptor trigger zone, the incidence and severity of chemotherapy-induced nausea and vomiting is decreased. Delayed emesis has been largely associated with the activation of tachykinin family neurokinin 1 (NK-1) receptors by substance P. Netupitant inhibits substance P–mediated responses. Palonosetron is partially metabolized by multiple CYP enzymes. Fosnetupitant is converted in vivo to netupitant by metabolic hydrolysis. Netupitant is extensively metabolized by CYP3A4 and to a lesser extent by other CYP enzymes. Palonosetron is excreted mostly through urine. Netupitant is excreted mostly through feces. The terminal half-life of palonosetron is 31 to 85 hours. The terminal half-life of fosnetupitant (as the prodrug) is 0.35 to 1.15 hours, and the terminal half-life of netupitant is 71 to 217 hours.

INDICATIONS AND USES

Indicated in combination with dexamethasone in adults for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of highly emetogenic cancer chemotherapy.

Limitation of use:

The injection has not been studied for the prevention of nausea and vomiting associated with anthracycline plus cyclophosphamide chemotherapy.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Hypersensitivity reactions, including anaphylaxis, have occurred with or without known hypersensitivity to other 5-HT_3 antagonists. ■ Serotonin syndrome has been reported with 5-HT_3 receptor antagonists. Most reports were associated with concomitant use of serotonergic drugs; see Drug/Lab Interactions.

Monitor:

Monitor for S/S of hypersensitivity reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for serotonin syndrome, especially when fosnetupitant/palonosetron is used concurrently with other serotonergic drugs. S/S associated with serotonin syndrome may include mental status changes (e.g., agitation, coma, delirium, hallucinations), autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile blood pressure, tachycardia), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), and seizures, with or without GI symptoms (e.g., diarrhea, nausea, vomiting). ■ See Antidote.

Patient Education:

Read FDA-approved patient information. ■ Review prescription and nonprescription medications with health care provider. ■ Review other medical conditions with health care provider. ■ Notify provider of known or suspected pregnancy. ■ Promptly report S/S of hypersensitivity reactions (e.g., hives, swollen face, trouble breathing, chest pain). ■ Promptly report S/S of serotonin syndrome (e.g., altered mental status, autonomic instability, and neuromuscular symptoms); see Precautions.

Maternal/Child:

Based on animal studies, there may be a potential risk to the fetus when administered during pregnancy. ■ Safety for use during breast-feeding not established; effects unknown. ■ The safety and effectiveness for use in patients under 18 years of age have not been established.

Elderly:

Safety and effectiveness similar to younger adults; however, greater sensitivity in some elderly patients cannot be ruled out.

DRUG/LAB INTERACTIONS

Netupitant is a moderate inhibitor of CYP3A4. Use fosnetupitant and palonosetron with caution in patients receiving concomitant medications that are primarily metabolized through CYP3A4. A single dose of netupitant 300 mg significantly inhibits CYP3A4 for 6 days. Avoid concomitant use of drugs that are **CYP3A4 substrates** for 1 week, if possible. If not avoidable, consider dose reduction of CYP3A4 substrates. ■ A single dose of fosnetupitant increased the systemic exposure of concomitant **dexamethasone** more than twofold on Days 2 and 4. Administer a reduced dose of dexamethasone with treatment; see Usual Dose. ■ Systemic exposure of **benzodiazepines** metabolized via CYP3A4 (e.g., alprazolam, midazolam) is increased with coadministration. ■ The systemic exposure of **chemotherapy agents metabolized by CYP3A4** (e.g., cyclophosphamide, docetaxel, etoposide, ifosfamide, imatinib, irinotecan, paclitaxel, vinblastine, vincristine, and vinorelbine) can increase when administered in combination with fosnetupitant and palonosetron. Monitor for chemotherapy-related adverse reactions with concomitant use. ■ The effects of fosnetupitant and palonosetron on INR and prothrombin time have not been studied. With concomitant use of **warfarin** and fosnetupitant and palonosetron, monitor INR and adjust the dosage of warfarin to maintain target INR range as needed. ■ **Strong CYP3A inducers** (e.g., rifampin) can decrease the effectiveness of fosnetupitant and palonosetron; concomitant use should be avoided. ■ Use with strong **CYP3A4 inhibitors** (e.g., ketoconazole) can increase the systemic exposure to the netupitant component; no dose adjustment indicated for single-dose administration. ■ Serotonin syndrome (including altered mental status, autonomic instability, and neuromuscular symptoms) has been reported following the concomitant use of 5-HT_3 receptor antagonists and **other serotonergic drugs** (e.g., **selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, monoamine oxidase inhibitors, mirtazapine, fentanyl, lithium, tramadol,** and intravenous **methylene blue**).

SIDE EFFECTS

The most common adverse reactions with IV infusion or oral capsules are asthenia, constipation, dyspepsia, erythema, fatigue, and headache. Safety profiles are similar. Other side effects included concomitant elevations of transaminases and total bilirubin. Serious side effects include hypersensitivity reactions and serotonin syndrome.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. In the event of overdose, discontinue treatment and provide general supportive treatment and monitoring. Dialysis studies have not been performed. Discontinue fosnetupitant and palonosetron if a hypersensitivity reaction occurs and treat as indicated (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressor, and/or fluids). If S/S of serotonin syndrome occur, discontinue treatment and initiate supportive care. Resuscitate as indicated.

FOSPHENYTOIN SODIUM BBW

(**FOS**-fen-ih-toyn **SO**-dee-um)
Cerebyx
Anticonvulsant (hydantoin)
pH 8.6 to 9

USUAL DOSE

Pretreatment:

See Maternal/Child.

1.5 mg of fosphenytoin sodium is equivalent to 1 mg phenytoin sodium and is referred to as 1 mg phenytoin sodium equivalents (PE). The amount and concentration of fosphenytoin is always expressed in terms of mg PE. Fosphenytoin 15 to 20 mg PE/kg is equivalent to phenytoin 15 to 20 mg/kg, or a 1,000-mg PE dose of fosphenytoin is equivalent to a 1,000-mg dose of phenytoin. Because of the risk of severe hypotension and cardiac arrhythmias, fosphenytoin should be administered no faster than 150 mg PE/min; see Rate of Administration, Precautions, and Monitor.

Status epilepticus:

Adult loading dose: 15 to 20 mg PE/kg administered at 100 to 150 mg PE/min. Full effect is not immediate; concomitant administration of an IV benzodiazepine (e.g., lorazepam) is usually necessary to control status epilepticus. If seizures are not controlled, consider other anticonvulsants and other measures as needed (e.g., barbiturates or anesthesia).

Nonemergent indications:

Loading dose: 10 to 20 mg PE/kg. ***Maintenance dose (for status epilepticus and nonemergent situations):*** 4 to 6 mg PE/kg/24 hr in divided doses. After administration of a loading dose, maintenance doses should typically be started at the next identified dosing interval. Because of the risk of cardiac and local toxicity associated with IV fosphenytoin, oral phenytoin should be administered whenever possible. See all comments under Usual Dose. See Elderly.

Substitute for oral phenytoin:

May be substituted at the same total daily phenytoin sodium equivalents (PE) dose. (Due to a 10% increase in bioavailability [IV/IM to oral], plasma levels with the IV/IM product may be increased slightly.)

PEDIATRIC DOSE

See comments in Usual Dose.

Status epilepticus loading dose:

15 to 20 mg PE/kg at a rate of 2 mg PE/kg/min (or 150 mg PE/min, whichever is lower).

Nonemergent loading dose:

10 to 15 mg PE/kg at a rate of 1 to 2 mg PE/kg/min (or 150 mg PE/min, whichever is lower).

Maintenance dose (for status epilepticus and nonemergent situations):

4 to 8 mg PE/kg/24 hr divided into 2 equal doses (2 to 4 mg PE/kg every 12 hours). Maintenance doses should be started 12 hours after the loading dose and then continued every 12 hours at a rate of 1 to 2 mg PE/kg/min (or 100 mg PE/min, whichever is lower). Because of the risks of cardiac and local toxicity, oral phenytoin should be used whenever possible. IM administration of fosphenytoin is not recommended in pediatric patients unless IV access is not possible.

DOSE ADJUSTMENTS

After the initial maintenance dose, subsequent maintenance doses should be individualized by monitoring serum levels of phenytoin to achieve a target therapeutic concentration. ■ Lower or less frequent dosing may be required in elderly patients. ■ Reduced doses may be required in the elderly, in impaired renal or hepatic function, or in patients with hypoalbuminemia. ■ See Precautions, Monitor, Drug/Lab Interactions, and Antidote.

DILUTION

Use only clear solutions. Available in a 100 mg PE/2 mL or a 500 mg PE/10 mL single-dose vial (50 mg PE/mL). ***Do not confuse the concentration of fosphenytoin with the total amount of the drug in the vial; serious errors have occurred. Do not confuse the amount of drug to be given in PE with the concentration of the drug in the vial.*** Should be diluted in D5W or NS to a concentration of 1.5 to 25 mg PE/mL. Dilute each milliliter of fosphenytoin with 1 mL of diluent to equal 25 mg PE/mL. Dilute a 1,000-mg PE dose in 100 mL diluent to equal 10 mg PE/mL.

Storage:

Keep refrigerated; do not store at room temperature for more than 48 hours. For single use only. Discard any unused product after opening.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Although the risk of cardiovascular toxicity increases with infusion rates above the recommended infusion rate, these events have also been reported at or below the recommended infusion rates. Slow the rate of infusion or temporarily stop infusion for cardiovascular side effects or for burning, itching, numbness, or pain along injection site.

Adults:

Each 100 to 150 mg PE or fraction thereof over a minimum of 1 minute. Do not exceed a rate of 150 mg PE/min.

Pediatric patients:

Loading dose: Do not exceed a rate of 2 mg PE/kg/min (or 150 mg PE/min, whichever is lower). ***Maintenance doses:*** Do not exceed a rate of 1 to 2 mg PE/kg/min (or 100 mg PE/min, whichever is lower).

ACTIONS

A water-soluble prodrug of phenytoin. Maximum fosphenytoin concentrations are achieved at the end of the infusion. Converts to phenytoin, phosphate, and formaldehyde after IV/IM administration, with a conversion half-life of approximately 15 minutes. An anticonvulsant, chemically related to barbiturates. Selectively stabilizes seizure threshold and depresses seizure activity in the motor cortex. Modulation of voltage-dependent sodium channels of neurons thought to be the primary cellular mechanism responsible for anticonvulsant activity. Extensively bound to protein, fosphenytoin displaces phenytoin from protein binding sites and increases free phenytoin (dose and rate dependent). Phenytoin's half-life is 12 to 28.9 hours. It is metabolized in the liver by hepatic cytochrome P_{450} enzymes (CYP2C9 and CYP2C19) and excreted in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of generalized tonic-clonic status epilepticus. ■ Treatment or prophylaxis of seizures in neurosurgical patients. ■ Substitute for oral phenytoin when oral administration is not feasible or prompt increases in antiepileptic drug levels are needed.

CONTRAINDICATIONS

History of hypersensitivity to fosphenytoin or its inactive components or to phenytoin or other hydantoins. Reactions have included angioedema. ■ Sinus bradycardia, sinoatrial block, second- and third-degree AV block, or Adams-Stokes syndrome because of the effect of parenteral phenytoin or fosphenytoin on ventricular automaticity. ■ A history of acute hepatotoxicity attributable to fosphenytoin or phenytoin. ■ Coadministration with delavirdine (Rescriptor); see Drug/Lab Interactions.

PRECAUTIONS

Doses of fosphenytoin are expressed in terms of milligrams of phenytoin equivalents (mg PE) to avoid the need to perform molecular weight–based adjustments when substituting fosphenytoin for phenytoin or vice versa; no adjustment required when substituting fosphenytoin or vice versa. Labeling of fosphenytoin has been updated by the manufacturer to reduce the incidence of dosing errors. To ensure accuracy, confirm actual dose and volume to be administered with a pharmacist or another RN. ■ Advantages of fosphenytoin over present phenytoin products include solubility in IV solutions, improved infusion site tolerance, more rapid rate of administration, and well-tolerated IM option. ■ IV route indicated in emergency situations (e.g., status epilepticus). May be given IM to adults in nonemergency situations. ■ Oral phenytoin is preferred in nonemergency situations because of the risks of cardiac and local toxicity associated with IV fosphenytoin. Adverse cardiovascular reactions have occurred during and after infusions and have been reported with infusion rates above the recommended rate as well as with infusion rates at or below the recommended rate. ■ May cause severe cardiovascular reactions (e.g., severe hypotension, bradycardia, various degrees of AV block, QT interval prolongation, ventricular tachycardia, ventricular fibrillation) that have resulted in asystole, cardiac arrest, and death; use extreme caution in elderly or seriously ill patients and in patients with hypotension or severe myocardial insufficiency. Risk of severe hypotension and cardiac arrhythmias increased by higher IV doses and/or rapid administration. ■ Intended for short-term parenteral use (up to 5 days). ■ Transfer to oral phenytoin therapy as soon as feasible. ■ Abrupt withdrawal of antiepileptic drugs may cause increased seizure activity, including status epilepticus. Gradually reduce dose, discontinue, or substitute alternative antiepileptic agents. ■ Discontinue immediately for hypersensitivity reactions; with caution rapidly substitute a nonhydantoin anticonvulsant. ■ Angioedema has been reported. ■ In patients who have experienced phenytoin hypersensitivity, alternatives to structurally similar drugs such as carbamazepine, barbiturates, succinimides, and oxazolidinediones should be considered. ■ May exacerbate porphyria. ■ Drug reaction with eosinophilia and systemic symptoms (DRESS), also known as multiorgan hypersensitivity, has been reported. DRESS usually presents with fever, rash, and/or lymphadenopathy and/or facial swelling in association with other organ system involvement such as hepatitis, nephritis, hematologic abnormalities, myocarditis, or myositis. Eosinophilia is often present. Deaths have been reported. ■ May cause acute phenytoin hepatotoxicity, which may manifest as elevated liver function tests, jaundice, hepatomegaly, leukocytosis, eosinophilia, and/or acute hepatic failure. These events may be part of the spectrum of DRESS or may occur in isolation. Discontinue immediately, do not readminister, and substitute alternate anticonvulsant therapy. ■ Has caused hematopoietic complications (e.g., agranulocytosis, granulocytopenia, leukopenia, thrombocytopenia, or pancytopenia with or without bone marrow suppression). ■ Some reports suggest a relationship between phenytoin and the development of lymphadenopathy (local or generalized), including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin disease. Lymph node involvement may occur with or without S/S resembling DRESS. In all cases of lymphadenopathy, follow-up observation for an extended period is indicated, and alternative anticonvulsant therapy should be strongly considered. ■ Sensory disturbances, including severe burning, itching, and paresthesia, have been reported; more common with higher doses and/or rates. The occurrence and intensity of discomfort may be lessened by slowing or temporarily stopping the infusion. No permanent sequelae have been reported. ■ Purple glove syndrome (edema, discoloration, and pain distal to the injection site) has occurred and may or may not be associated with extravasation. The syndrome may not develop for several days. ■ Severe cutaneous adverse reactions (SCARs) have been reported, including toxic epidermal necrolysis (TEN), Stevens-Johnson syndrome (SJS), acute generalized exanthematous pustulosis (AGEP), and DRESS. Deaths have occurred. Onset of symptoms is usually within 28 days but may occur later. Discontinue fosphenytoin at the first sign of a rash unless the rash is clearly not drug related. If a rash develops, the patient should be evaluated for S/S of SCARs. ■ Selected patients of Asian ancestry with a specific human leukocyte antigen allele (HLA-B*1502) may have an increased risk of serious skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis) from phenytoin therapy. ■ Use caution in patients with impaired renal or hepatic function or in patients with hypoalbuminemia. After an IV loading dose, fosphenytoin clearance to phenytoin may be increased without a similar increase in phenytoin clearance. This, together with an increased fraction of unbound phenytoin in these patient populations, may increase the incidence and frequency of adverse reactions. ■ Use caution with low serum albumin levels, and adjust dose as indicated. Phenytoin is highly bound to serum protein, and a reduced albumin causes an increase in free drug availability and may increase toxicity. ■ Not effective for absence seizures; combined therapy required if both conditions present. ■ Not indicated for seizures due to hypoglycemia or other metabolic causes. ■ Inhibits insulin release and may increase serum glucose; monitoring indicated in diabetics. ■ May lower serum folate levels. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. Some psychotic symptoms and/or behavioral changes resolved without intervention. Others required dose reduction or discontinuation of the antiepileptic agent. ■ Confusional states referred to as delirium, psychosis, encephalopathy or, rarely, irreversible cerebellar dysfunction and/or cerebellar atrophy have been reported when plasma phenytoin concentrations are sustained above the optimum range. At the first sign of acute toxicity, determination of plasma phenytoin concentration is recommended. Reduce dose if indicated. If symptoms persist, discontinue fosphenytoin. ■ A small percentage of patients may be slow metabolizers of phenytoin. This appears to be genetically determined. If early signs of dose-related CNS toxicity develop, obtain serum levels immediately.

Monitor:

Monitor ECG, BP, and respirations continuously during loading dose and for at least 10 to 20 minutes after infusion is complete. ■ Allow fosphenytoin time to convert to phenytoin; accurate serum levels are not available until 2 hours after the end of an IV infusion or 4 hours after IM injection. Narrow margin of error between therapeutic and toxic dose. Plasma levels above 10 mcg/mL usually control seizure activity. The acceptable range is 5 to 20 mcg/mL (unbound phenytoin concentration of 1 to 2 mcg/mL). Toxicity usually begins with nystagmus at levels exceeding 20 mcg/mL. ■ Because the unbound fraction of phenytoin is increased in patients with renal or hepatic disease or in those with hypoalbuminemia, the monitoring of phenytoin serum levels should be based on the unbound fraction. ■ Periodic monitoring of CBC, liver function, and blood glucose levels recommended. ■ Monitor for S/S of hypersensitivity reactions. Observe for rash and discontinue if one appears. If rash is mild, fosphenytoin may be resumed when the rash has completely disappeared. Discontinue fosphenytoin if the mild rash occurs again, if the initial rash is serious in nature (e.g., exfoliative, purpuric, bullous), or if Stevens-Johnson syndrome or toxic epidermal necrolysis is suspected. Do not resume; consider alternative therapy. ■ Monitor for symptoms of angioedema (e.g., facial, perioral, or upper airway swelling). ■ Phosphate is produced as a metabolite; monitor in patients who require phosphate restriction (e.g., renal impairment). ■ Monitor patients who are gravely ill, have impaired liver or renal function or hypoalbuminemia, or are elderly. May show early signs of toxicity. ■ Determine absolute patency of vein; avoid extravasation. Not as alkaline as phenytoin. ■ Observe patient closely for signs of CNS side effects; see Precautions.

Patient Education:

Effective birth control required for women of childbearing potential who are not planning a pregnancy. Hormonal contraceptive efficacy may be decreased; see Maternal/Child. ■ Capable of numerable drug interactions. Review list of over-the-counter and prescription medications and alcohol use with provider. ■ Promptly report burning, itching, numbness, pain, or rash. ■ Promptly report chills and/or fever and S/S of cardiovascular toxicity, an infusion reaction, a hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, nausea, shortness of breath), or S/S of angioedema (e.g., facial, perioral, or upper airway swelling). ■ May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of the S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry.

Maternal/Child:

Avoid pregnancy. Prenatal exposure to phenytoin may increase the risk of congenital malformations and other adverse developmental outcomes. Consider risk versus benefit. ■ Decreased serum concentrations of phenytoin may occur during pregnancy and may result in increased seizure frequency. Periodic serum phenytoin concentrations should be performed based on the unbound fraction because of potential changes in protein binding during pregnancy; adjust dose as indicated. ■ Newborns whose mothers received phenytoin during pregnancy may develop a life-threatening bleeding disorder that can be prevented by giving vitamin K to the mother before delivery and to the neonate after birth. ■ Active metabolite of fosphenytoin (phenytoin) is secreted in breast milk; consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients has been established. ■ See Patient Education.

Elderly:

See Dose Adjustments. ■ Sensitivity and/or toxicity may be increased because serum concentrations may be elevated due to reduced clearance, or low serum albumin may cause a decrease in protein binding and an increase in free phenytoin.

DRUG/LAB INTERACTIONS

No drugs are known to interfere with the conversion of fosphenytoin to phenytoin, although phosphatase activity may have an impact. ■ ***Capable of innumerable catastrophic drug interactions; review of drug profile by pharmacist imperative.*** In all situations, monitoring of phenytoin serum levels may be indicated. ■ Phenytoin is highly protein bound and is prone to competitive displacement. ■ Phenytoin is metabolized by CYP2C9 and CYP2C19 and is particularly susceptible to inhibitory drug interactions because it is subject to saturable metabolism. Inhibition of metabolism may produce significant increases in circulating phenytoin concentrations, increasing the risk of toxicity. ■ Coadministration with **delavirdine** is contraindicated. Has the potential for loss of virologic response and possible resistance to delavirdine or to the class of nonnucleoside reverse transcriptase inhibitors. ■ Serum levels and toxicity of phenytoin may be increased by **alcohol (acute intake), amiodarone, antiepileptic agents** (e.g., felbamate, topiramate, oxcarbazepine), **azoles** (e.g., fluconazole, itraconazole, ketoconazole, miconazole, voriconazole), **capecitabine, chloramphenicol, chlordiazepoxide, disulfiram, estrogens, fluorouracil, fluoxetine, fluvastatin, fluvoxamine, H_2 antagonists**, **halothane, isoniazid, methylphenidate, omeprazole, phenothiazines, salicylates** (aspirin), **sertraline, succinimides** (e.g., ethosuximide), **sulfonamides** (e.g., sulfamethizole, sulfamethoxazole/trimethoprim), **tolbutamide, trazodone, and warfarin**. ■ Serum levels and effectiveness of phenytoin may be decreased by **anticancer drugs, antivirals** (e.g., fosamprenavir, nelfinavir, ritonavir), **carbamazepine, chronic alcohol abuse, diazepam, diazoxide, folic acid, reserpine, rifampin, St. John's wort, theophylline, and vigabatrin.** ■ Serum levels of phenytoin may be increased or decreased by **phenobarbital, valproate sodium, valproic acid.** Similarly, phenytoin may unpredictably affect the levels and efficacy of these drugs. ■ Phenytoin will inhibit the effects of **azole antifungals** (e.g., fluconazole, posaconazole, voriconazole), **corticosteroids, doxycycline, estrogens, furosemide, irinotecan, oral contraceptives, paclitaxel, paroxetine, quinidine, rifampin, sertraline, teniposide, theophylline, and vitamin D.** Dose adjustment of these agents may be indicated. ■ Decreases plasma concentrations of **active metabolites of albendazole, antiepileptic agents, atorvastatin,** certain **HIV antivirals** (e.g., efavirenz, lopinavir/ritonavir, indinavir, nelfinavir, ritonavir, saquinavir), **chlorpropamide, clozapine, cyclosporine, digoxin, fluvastatin, folic acid, methadone, mexiletine, nifedipine, nimodipine, nisoldipine, praziquantel, quetiapine, simvastatin,** and **verapamil**. Adjust doses of these agents as indicated. ■ May increase or decrease PT/INR responses when coadministered with **warfarin**. ■ When given with **fosamprenavir** alone, phenytoin may decrease the concentration of **amprenavir**, the active metabolite. When given in combination with **fosamprenavir and ritonavir**, phenytoin may increase the concentration of **amprenavir**. ■ Resistance to the neuromuscular blocking action of the **nondepolarizing neuromuscular blocking agents** pancuronium, vecuronium, rocuronium, and cisatracurium has occurred in patients receiving long-term administration of phenytoin. Monitor for more rapid than expected recovery from neuromuscular blockade. ■ Alters some **clinical laboratory tests** (e.g., may decrease T_4, increase glucose, alkaline phosphatase, and gamma-glutamyl transferase (GGT); may produce low results in dexamethasone or metyrapone tests).

SIDE EFFECTS

Transient ataxia, dizziness, nystagmus, paresthesia, pruritus, and somnolence are the most common side effects in adults and are dose- and rate-related. Ataxia, nystagmus, and vomiting are the most common side effects in pediatric patients. Risks of side effects increased with upper-end doses given at upper-end rates. The more important adverse clinical events caused by IV use of fosphenytoin are cardiovascular collapse and/or CNS depression. Coma, hyperreflexia, hypotension, lethargy, nausea, slurred speech, tremor, and vomiting are also signs of increased toxicity. Confusional states (e.g., delirium, encephalopathy, psychosis) and, rarely, irreversible cerebellar dysfunction can occur with high plasma concentrations. Fosphenytoin breaks down into formate and phosphate metabolites that may cause formate and phosphate toxicity in overdose situations (hypocalcemia, metabolic acidosis, muscle spasms, paresthesia, and seizures). Psychotic symptoms, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have occurred with antiepileptic agents. Several other adverse reactions have been reported.

Overdose:

Arrhythmias (e.g., asystole, bradycardia, cardiac arrest, tachycardia), ataxia, coma, dysarthria, hepatotoxicity, hyperreflexia, hypocalcemia, hypotension, lethargy, metabolic acidosis, nausea, nystagmus, slurred speech, syncope, tremor, and vomiting. Deaths from circulatory and respiratory depression have been reported. The lethal dose of phenytoin in adults is estimated to be 2 to 5 Gm. The lethal dose in pediatric patients is not known.

Post-Marketing:

Anaphylactoid reactions, including anaphylaxis and angioedema; dyskinesia; laboratory test abnormalities, including decreased serum concentrations of T4, lower than normal values for dexamethasone or metyrapone tests, and increased serum levels of GGT.

ANTIDOTE

Notify physician of any side effects. Obtain serum plasma levels at first signs of toxicity; reduce dose. If serum levels are excessive, symptoms persist or major side effects appear, discontinue fosphenytoin and notify physician. Treat symptomatically, maintain a patent airway, and resuscitate as necessary. Discontinue fosphenytoin at the first sign of a rash unless the rash is clearly not drug related. If TEN or SJS is suspected, do not rechallenge; consider alternate therapy. Discontinue immediately if symptoms of angioedema develop. Evaluate for multiorgan hypersensitivity reactions (DRESS). Cardiovascular toxicity, including hypotension or cardiac arrhythmias, may respond to a decrease in infusion rate. Consider hemodialysis in overdose (phenytoin [the active metabolite of fosphenytoin] is not completely bound to plasma proteins). Total exchange transfusion has been used in the treatment of severe intoxication in pediatric patients. In acute overdose, consider the possibility of other CNS depressants, including alcohol. In overdose, measure ionized free calcium levels to guide treatment in phosphate toxicity.

FOSPROPOFOL DISODIUM

(**FOS**-proh-poh-fohl)
Lusedra
Sedative–hypnotic
Anesthetic
Anesthesia adjunct
pH 8.2 to 9

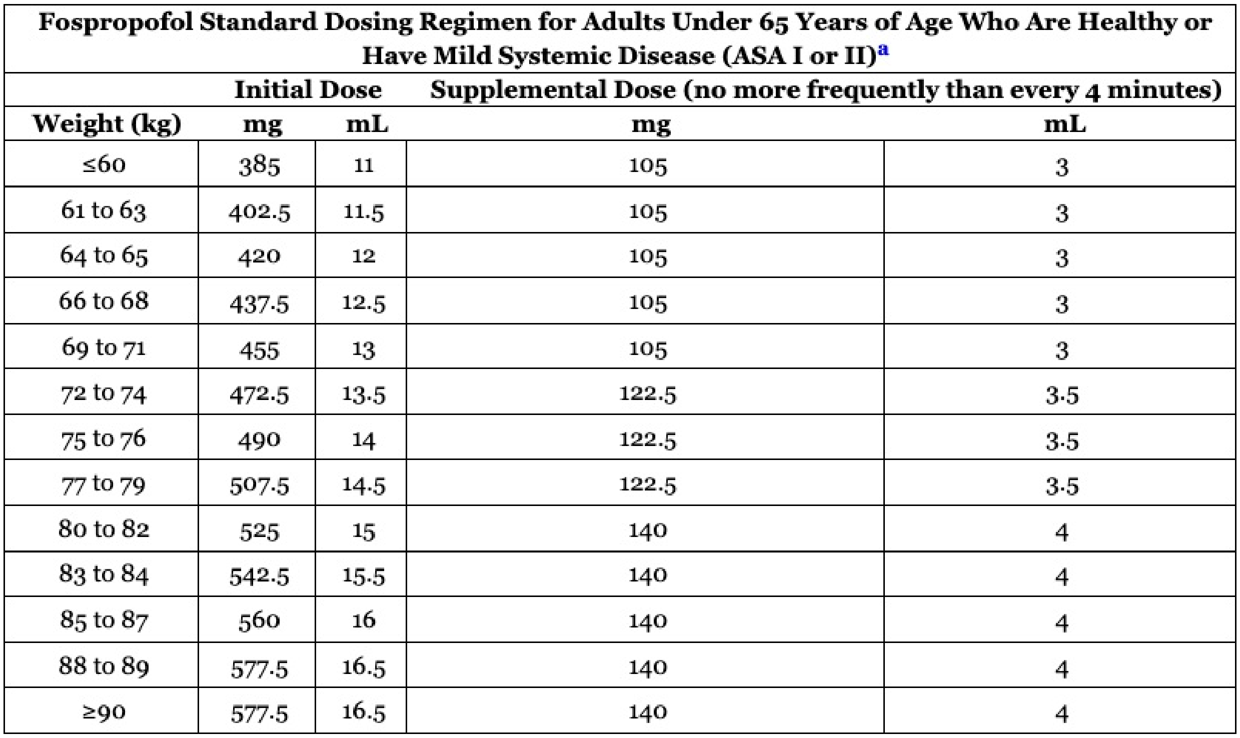
USUAL DOSE

Supplemental oxygen and continuous monitoring required; see Monitor. Dose must be individualized and titrated to desired level of sedation. Use the minimum dose required to facilitate the procedure. In clinical studies, fentanyl 50 mcg was administered as a premedication 5 minutes before the initial dose of fospropofol.

Standard dosing regimen for healthy adults under 65 years of age or those with mild systemic disease (ASA I or II):

6.5 mg/kg as an initial IV bolus. Follow with supplemental doses of 1.6 mg/kg (25% of initial dose) as an IV bolus as needed to achieve the desired level of sedation. Administer supplemental doses based on the patient’s level of sedation. Give supplemental doses only when patients can demonstrate purposeful movement in response to verbal or light tactile stimulation and not more frequently than every 4 minutes. Dose is limited by the lower and upper weight limits of 60 kg and 90 kg. Patients who weigh over 90 kg should be dosed as if they weigh 90 kg. ***No initial dose should exceed 16.5 mL; no***

supplemental dose should exceed 4 mL. Patients who weigh less than 60 kg should be dosed as if they weigh 60 kg. However, doses lower than those specified for the lower weight limit may be used to achieve lesser levels of sedation. See the following table for the standard dosing regimen described earlier.



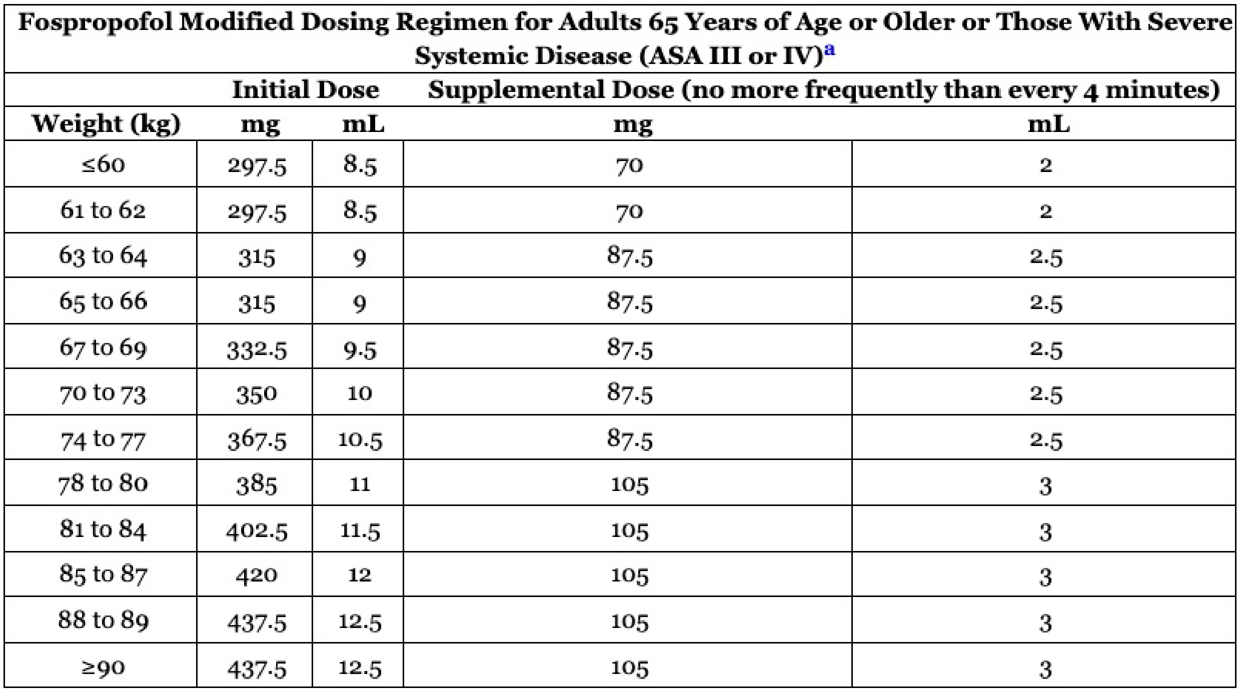
Fospropofol Standard Dosing Regimen for Adults Under 65 Years of Age Who Are Healthy or Have Mild Systemic Disease (ASA I or II)[a]

	Initial Dose		Supplemental Dose (no more frequently than every 4 minutes)	
Weight (kg)	**mg**	**mL**	**mg**	**mL**
≤60	385	11	105	3
61 to 63	402.5	11.5	105	3
64 to 65	420	12	105	3
66 to 68	437.5	12.5	105	3
69 to 71	455	13	105	3
72 to 74	472.5	13.5	122.5	3.5
75 to 76	490	14	122.5	3.5
77 to 79	507.5	14.5	122.5	3.5
80 to 82	525	15	140	4
83 to 84	542.5	15.5	140	4
85 to 87	560	16	140	4
88 to 89	577.5	16.5	140	4
≥90	577.5	16.5	140	4

[a] **Note:** Doses in this table are rounded to the nearest half-milliliter volume to facilitate practical measurement; hence they may differ slightly from the dose recommended on the basis of mg/kg.

Modified dosing regimen for adults 65 years of age or older or those with severe systemic disease (ASA III or IV):

Decrease initial and supplemental doses to 75% of the standard dosing regimen as listed in the following table.



Fospropofol Modified Dosing Regimen for Adults 65 Years of Age or Older or Those With Severe Systemic Disease (ASA III or IV)[a]				
	Initial Dose		Supplemental Dose (no more frequently than every 4 minutes)	
Weight (kg)	mg	mL	mg	mL
≤60	297.5	8.5	70	2
61 to 62	297.5	8.5	70	2
63 to 64	315	9	87.5	2.5
65 to 66	315	9	87.5	2.5
67 to 69	332.5	9.5	87.5	2.5
70 to 73	350	10	87.5	2.5
74 to 77	367.5	10.5	87.5	2.5
78 to 80	385	11	105	3
81 to 84	402.5	11.5	105	3
85 to 87	420	12	105	3
88 to 89	437.5	12.5	105	3
≥90	437.5	12.5	105	3

[a] **Note:** Doses in this table are rounded to the nearest half-milliliter volume to facilitate practical measurement; hence they may differ slightly from the dose recommended on the basis of mg/kg.

DOSE ADJUSTMENTS

See Usual Dose for specific reduced doses required for adults 65 years of age or older or ASA risk III or IV patients. ■ Reduced doses are required in the presence of other CNS depressants; see Drug/Lab Interactions. ■ Reduced doses are not required based on race, gender, age, alkaline phosphatase concentrations, or mild to moderate renal impairment. ■ Has not been adequately studied in patients with a CrCl less than 30 mL/min or in patients with hepatic impairment.

DILUTION

Supplied as a ready-to-use solution containing 35 mg/mL of fospropofol (1,050 mg/30 mL vial). Intended for single use. Strict aseptic technique is imperative. Draw solution into a sterile syringe immediately after vial is opened. Discard any unused portion at the end of the procedure.

Filter:

Not required. Information not available.

Storage:

Store at CRT. Draw up into syringe immediately after opening vial, and discard any unused solution at the end of the procedure.

COMPATIBILITY

Manufacturer states, “Do not mix with other drugs or fluids prior to administration. Is **not physically compatible** with midazolam or meperidine, and **compatibility** with other agents has not been adequately evaluated. Flush the infusion line with NS before and after administration.” Has been shown to be **compatible** with the following solutions: D5W, D5/¼NS, D5/½NS, NS, LR, D5LR, ½NS, D5/½NS, and 20 mEq KCl.

RATE OF ADMINISTRATION

Administer as a bolus injection.

ACTIONS

A sedative-hypnotic agent. A prodrug of propofol. Following injection, fospropofol is metabolized by alkaline phosphatases to propofol, which interacts with the GABA (gamma-aminobutyric acid) receptors of the CNS, resulting in sedation. In clinical studies, peak plasma levels of propofol released from fospropofol were noted within 12 minutes. In patients undergoing a colonoscopy, the median time to sedation was 8 minutes (range 2 to 28 minutes), and the median time to Fully Alert following the procedure was 5 minutes (range 0 to 47 minutes). In patients undergoing a bronchoscopy, the median time to sedation was 4 minutes (range 2 to 22 minutes), and the median time to Fully Alert following the procedure was 5.5 minutes (range 0 to 6 minutes). Both fospropofol and its active metabolite propofol are highly protein bound, primarily to albumin. Propofol is further metabolized in the liver. The half-lives of fospropofol and propofol are approximately 0.8 and 2 hours, respectively. Propofol is excreted as metabolites in the urine.

INDICATIONS AND USES

To initiate and maintain monitored anesthesia care (MAC) sedation in adult patients undergoing diagnostic or therapeutic procedures.

CONTRAINDICATIONS

Manufacturer states, “None.” See Precautions.

PRECAUTIONS

Administered by persons trained in the administration of general anesthesia and not involved in the conduct of the diagnostic or therapeutic procedure. Patients should be continuously monitored, and facilities and supplies for responding to any medical emergency must be immediately available. ■ Respiratory depression, including the loss of spontaneous respirations, may occur. Supplemental oxygen is recommended for all patients. Hypoxemia may occur and has been seen in patients who retained the ability to respond purposefully. The risk of hypoxemia is reduced by appropriate positioning of the patient and the administration of supplemental oxygen. ■ Has not been studied for use in general anesthesia and is not recommended. Administration may inadvertently cause patients to become unresponsive or minimally responsive to vigorous tactile or painful stimulation. ■ May cause hypotension. Patients with compromised myocardial function, reduced vascular tone (e.g., sepsis), or reduced intravascular volume may be at an increased risk for hypotension. ■ Use with caution in patients with hepatic impairment or severe renal impairment (CrCl less than 30 mL/min). ■ Safety for continuous sedation has not been established and is not recommended. ■ See Drug/Lab Interactions.

Monitor:

Patients should be continuously monitored during sedation and through the recovery process with pulse oximetry, ECG, and frequent BP measurements for early signs of arrhythmia, hypotension, apnea, airway obstruction, and/or oxygen desaturation. Hypoxemia may be detected by pulse oximetry. ■ Assess patients for the ability to demonstrate a purposeful response while sedated. Patients who are unable to demonstrate a purposeful response may lose protective reflexes. Airway assistance maneuvers may be required. ■ Correct fluid volume deficiencies before administration.

Patient Education:

Paresthesias and/or pruritus, usually manifested in the perineal region, are common side effects. Side effects are usually mild to moderate in intensity and of short duration. ■ Avoid alcohol or other CNS depressants (e.g., antihistamines, benzodiazepines) for 24 hours following the procedure. ■ Do not perform tasks that require mental alertness (e.g., driving, operating hazardous machinery, or signing legal documents) until the day after surgery or longer. All effects must have subsided.

Maternal/Child:

Category B: use during pregnancy only if clearly needed. Use during labor and delivery, including cesarean section, is not recommended. It is not known if fospropofol crosses the placenta; however, propofol is known to cross the placenta, and as with other sedative-hypnotic agents, the administration of fospropofol may be associated with neonatal respiratory and cardiovascular depression. ■ Use during breast-feeding not recommended. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Patients 65 years of age or older should receive the modified dosing regimen; see Usual Dose. Hypoxemia has been reported more frequently in the elderly.

DRUG/LAB INTERACTIONS

Potentiated by other medications that can depress cardiac or respiratory status (e.g., **narcotics** [e.g., morphine, meperidine (Demerol), fentanyl], **sedatives** [barbiturates, benzodiazepines (e.g., diazepam [Valium], midazolam [Versed])], chloral hydrate, droperidol [Inapsine]). ■ Has been administered with fentanyl, meperidine, midazolam, and morphine.

SIDE EFFECTS

The most commonly reported side effects are paresthesia (burning, stinging, tingling) and/or pruritus, usually manifested in the perineal region. The most serious side effects reported include hypotension, hypoxemia, loss of purposeful responsiveness, and respiratory depression. The most commonly reported reasons for discontinuation of therapy are cough and paresthesia. Other reported side effects include headache, nausea, procedural pain, and vomiting.

Overdose:

(Secondary to accumulation of formate and phosphate metabolites) Anion-gap metabolic acidosis, hypocalcemia with paresthesia, muscle spasms, and seizures.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. A short-acting drug, a patent airway, and continuous controlled ventilation with oxygen until normal function is ensured should be adequate. Treat hypotension with IV fluid replacement, Trendelenburg position, or vasopressors (e.g., dopamine) as indicated. Resuscitate as necessary.

FUROSEMIDE BBW

(fur-**OH**-seh-myd)
Lasix
Diuretic (loop)
pH 8 to 9.3

USUAL DOSE

Adjust dose and dose schedule to individual patient needs. Reserve parenteral therapy for emergent situations or for patients unable to take oral therapy. Switch to oral therapy as soon as practical.

Pretreatment:

Patient assessment may be indicated; see Precautions.

Edema:

20 to 40 mg. May be repeated in 2 hours. If necessary, increase dosage by 20-mg increments (under close medical supervision and no sooner than 2 hours after previous dose) until desired diuresis is obtained. After the initial diuresis the minimum effective dose may be given once or twice every 24 hours as required for maintenance.

Acute pulmonary edema:

40 mg. Dose may be increased to 80 mg after 1 hour if satisfactory response is not obtained. AHA guidelines recommend 0.5 mg/kg to 1 mg/kg over 1 to 2 minutes. If no response, increase to 2 mg/kg. For **new-onset pulmonary edema with hypovolemia**, a dose of less than 0.5 mg/kg is recommended. Additional therapy (e.g., digoxin, oxygen) may be administered concurrently as needed.

Hypertensive crisis (unlabeled):

AHA guidelines recommend 0.5 to 1 mg/kg over 1 to 2 minutes. If no response, increase dose to 2 mg/kg.

PEDIATRIC DOSE

See Maternal/Child.

Diuretic:

1 mg/kg of body weight. After 2 hours increase by 1-mg/kg increments to effect desired response. Do not exceed 6 mg/kg/dose. Effective dose may be given every 6 to 12 hours. Another source suggests 1 to 2 mg/kg/dose every 6 to 12 hours.

NEONATAL DOSE

Diuretic:

0.5 to 1 mg/kg/dose every 8 to 24 hours. Maximum dose is 2 mg/kg/dose. Literature reports suggest that the maximum dose for premature infants should not exceed 1 mg/kg/day. See Maternal/Child.

DOSE ADJUSTMENTS

Higher doses may be required in renal insufficiency and acute or chronic renal failure. ■ Reduced dose or extended intervals may be appropriate in the elderly. ■ Extend dosing intervals in neonates because half-life is prolonged. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. May be given through Y-tube or three-way stopcock of infusion set. Not usually added to IV solutions, but large doses may be added to NS, LR, or D5W and given as an infusion. Another source suggests it can be diluted with D5NS. pH of solution must be over 5.5. Some sources recommend protecting diluted solutions from light to prevent photodegradation (minimized at pH 7).

Filters:

One source found no significant drug loss when filtered through a 0.22-micron filter.

Storage:

Store vials at CRT. Protect from light. If diluted for infusion, discard after 24 hours.

COMPATIBILITY

Furosemide may precipitate at a pH below 7. Manufacturer states, “Acid solutions, including other parenteral medications (e.g., amrinone, ciprofloxacin, labetalol, milrinone), must not be administered concurrently in the same infusion.” Additionally, “Furosemide should not be added to an IV line containing any of these acidic products.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 40 mg or fraction thereof should be given over 1 to 2 minutes.

Infusion:

One source recommends the following: ***Adults:*** 0.1 mg/kg/hr. ***Pediatric patients:*** 0.05 mg/kg/hr. Titrate to effect. High-dose therapy in an infusion should not exceed a rate of 4 mg/min.

ACTIONS

A potent loop diuretic, structurally related to sulfonamides. Onset of action is prompt, usually within 5 minutes. Duration of action and half-life are approximately 2 hours. Inhibits the reabsorption of sodium and chloride in the proximal and distal tubules and in the loop of Henle, causing increased excretion of water, sodium, chloride, magnesium, and calcium. Highly protein bound. Metabolized and excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Parenteral therapy should be reserved for patients unable to take oral medications or for emergency clinical situations. ■ Edema associated with congestive heart failure, cirrhosis of the liver, and renal disease, including nephrotic syndrome. Particularly useful when an agent with a greater diuretic potential is required. ■ Adjunctive therapy in acute pulmonary edema. Indicated when rapid onset of diuresis is necessary (e.g., acute pulmonary edema).

CONTRAINDICATIONS

Anuria, hypersensitivity to furosemide.

PRECAUTIONS

A potent diuretic; may precipitate excessive diuresis with water and electrolyte depletion. Careful medical supervision is required. ■ Use caution and improve basic condition first in hepatic coma, electrolyte depletion, and advanced cirrhosis of the liver. Sudden alterations of fluid and electrolyte balance in patients with cirrhosis may precipitate hepatic coma. Supplemental potassium chloride and, if required, an aldosterone antagonist (e.g., spironolactone) are helpful in preventing hypokalemia and metabolic alkalosis. ■ Excessive diuresis may cause dehydration and blood volume reduction with circulatory collapse and possibly vascular thrombosis and embolism, particularly in the elderly. ■ If increasing azotemia and oliguria develop during treatment of severe progressive renal disease, furosemide should be discontinued. ■ Use caution in known sulfonamide sensitivity. Manufacturer states that patients allergic to sulfonamides may also be allergic to furosemide. However, current literature suggests that the potential for cross-reactivity between antibiotic sulfonamides and nonantibiotic sulfonamides is low. ■ Ototoxicity (tinnitus, reversible or irreversible hearing impairment and deafness) has been reported. Risk increases with higher doses, rapid injection, severe renal dysfunction, hypoproteinemia, or concurrent use with other ototoxic drugs; see Drug/Lab Interactions. ■ In patients with hypoproteinemia (e.g., associated with nephrotic syndrome), the effect of furosemide may be weakened and its ototoxicity potentiated. ■ May activate or exacerbate systemic lupus erythematosus. ■ Use caution in patients with severe symptoms of urinary retention (because of bladder emptying disorders, prostatic hypertrophy, urethral narrowing). May experience acute urinary retention related to increased production and retention of urine. Careful monitoring required, especially during the initiation of therapy.

Monitor:

Monitor BP frequently, especially during initial therapy. ■ May precipitate excessive diuresis with water and electrolyte imbalance (hyponatremia, hypochloremic alkalosis, hypokalemia, hypomagnesemia, or hypocalcemia). Routine checks on electrolyte panel, CO_2, SCr, and BUN are necessary during therapy. Electrolyte replacement may be required. ■ May increase blood glucose and has precipitated diabetes mellitus (rare). Monitoring may be indicated, especially in patients with diabetes or suspected latent diabetes. ■ Periodic monitoring of CBC and liver function tests are indicated to monitor for blood dyscrasias or liver damage. ■ Monitor for other S/S of fluid or electrolyte imbalance, which may include arrhythmia, drowsiness, dryness of the mouth, hypotension, lethargy, muscle cramps or fatigue, nausea or vomiting, oliguria, restlessness, tachycardia, thirst, and weakness. ■ May lower serum calcium level; may cause tetany. ■ Hyperuricemia can occur. Rarely precipitates acute gout attack. ■ See Drug/Lab Interactions.

Patient Education:

Hypotension may cause dizziness; request assistance with ambulation. ■ Report cramps, dizziness, muscle weakness, or nausea promptly. ■ May cause a decrease in potassium levels and require a supplement. ■ Skin may become photosensitive; avoid unprotected exposure to sun. ■ Therapy for diabetes may require adjustment; monitoring of serum glucose required.

Maternal/Child:

Category C: use during pregnancy only when clearly needed and benefits outweigh potential risks to fetus. Treatment during pregnancy requires monitoring of fetal growth because of the potential for higher fetal birth weights. ■ Use caution in breast-feeding; may inhibit lactation. ■ May precipitate nephrocalcinosis and nephrolithiasis in premature infants. Has also been observed in pediatric patients under 4 years of age who have been treated chronically with furosemide. Monitor renal function. Renal ultrasonography may be indicated. ■ Administration in the first few weeks of life may increase risk of persistent patent ductus arteriosus in preterm infants with respiratory distress syndrome. ■ Premature infants receiving doses exceeding 1 mg/kg/day may develop plasma levels that could be associated with toxicity, including ototoxicity. Hearing loss in neonates has been associated with the use of furosemide.

Elderly:

Protein binding and clearance are decreased in the elderly. ■ Consider increased sensitivity to hypotensive and electrolyte effects. Dose selection should be cautious, starting at the lower end of the dosing range. ■ May be more susceptible to dehydration; observe carefully. ■ Avoid rapid contraction of plasma volume and hemoconcentration. May cause thromboembolic episodes (e.g., CVA, pulmonary emboli). ■ The initial diuretic effect in older patients is decreased relative to younger patients.

DRUG/LAB INTERACTIONS

Concomitant use with **amphotericin B, corticosteroids, ACTH, licorice** in large amounts, or prolonged use of **laxatives** may increase the risk of hypokalemia. ■ Potentiates **antihypertensive drugs** (e.g., angiotensin II receptor blockers, nitroglycerin, nitroprusside sodium); reduced dose of the antihypertensive agent or both drugs may be indicated. In addition to hypotension, concomitant use with angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin II receptor blockers (ARBs) may lead to deterioration in renal function, including renal failure. An interruption or reduction in the dose of furosemide, ACEI, or ARB may be necessary. ■ May cause transient or permanent deafness with doses exceeding the usual or when given in conjunction with **other ototoxic drugs** (e.g., aminoglycosides [e.g., gentamicin], cisplatin), especially in the presence of renal impairment; avoid concomitant use if possible. Do not use concomitantly with **ethacrynic acid** (Edecrin); risk of ototoxicity markedly increased. ■ Nephrotoxicity increased by **other nephrotoxic agents** (e.g., aminoglycosides, cephalosporins, cisplatin, cyclosporine, radiocontrast agents, vancomycin). Monitor renal function closely. ■ Diuretics reduce the renal clearance of **lithium**, increasing the risk of toxicity. ■ May cause cardiac arrhythmias with **amiodarone or digoxin** (potassium depletion). ■ May enhance or inhibit actions of **nondepolarizing muscle relaxants**. ■ May potentiate the action of **succinylcholine.** ■ Effects may be inhibited by **NSAIDs** (e.g., ibuprofen) **or probenecid.** ■ May cause profound diuresis and serious electrolyte abnormalities with **thiazide diuretics** because of synergistic effects. ■ **Furosemide** may increase serum levels of salicylates, increasing the risk of toxicity. ■ May decrease arterial responsiveness to **norepinephrine.** Dose adjustment may be required. ■ May enhance adverse effects of **chloral hydrate.** Concomitant use not recommended. ■ **Methotrexate** and other drugs that undergo significant renal tubular secretion may decrease the effectiveness of furosemide. ■ Furosemide may decrease renal elimination of other drugs that undergo tubular secretion. High-dose treatment of both furosemide and these other drugs may result in elevated serum levels and may potentiate toxicity. ■ Concomitant use of **cyclosporine** and furosemide has been associated with increased risk of gouty arthritis secondary to furosemide-induced hyperuricemia and cyclosporine impairment of renal urate excretion. ■ Simultaneous administration of sucralfate and furosemide injection may reduce the natriuretic and antihypertensive effects of furosemide. Separate doses by at least 2 hours and monitor for desired effect. ■ High doses (greater than 80 mg) of furosemide may inhibit the binding of **thyroid hormones** to carrier proteins and result in a transient increase in free thyroid hormones followed by an overall decrease in total thyroid hormone levels. ■ See Precautions.

SIDE EFFECTS

Usually occur in prolonged therapy, seriously ill patients, or following large doses.

The most serious side effects include anaphylactic or anaphylactoid reactions (severe or with shock), aplastic anemia, drug rash with eosinophilia and systemic symptoms (DRESS), erythema multiforme, exanthematous pustulosis (acute, generalized), hepatic encephalopathy in patients with hepatocellular insufficiency, orthostatic hypotension (may be aggravated by alcohol, barbiturates, or narcotics), Stevens-Johnson syndrome, tinnitus and hearing loss, and toxic epidermal necrolysis. Anorexia; blurred vision; bullous pemphigoid; constipation; cramping; diarrhea; dizziness; exfoliative dermatitis; headache; hematologic reactions (agranulocytosis, anemia, eosinophilia, hemolytic anemia, GI cramping, leukopenia, thrombocytopenia); increased cholesterol, liver enzymes, and triglyceride serum levels; interstitial nephritis; jaundice (intrahepatic cholestatic jaundice); nausea; necrotizing angiitis; oral and gastric irritation; pancreatitis; paresthesias; photosensitivity; pruritus; purpura; rash; thrombocytopenia; urticaria; vasculitis (systemic); vertigo; vomiting; and xanthopsia have occurred. Fever, glycosuria, hyperglycemia, hyperuricemia, muscle spasms, restlessness, thrombophlebitis, transient injection site pain following IM injection, urinary bladder spasm, and weakness have also been reported.

Overdose:

Blood volume reduction, dehydration, electrolyte imbalances, hypochloremic alkalosis, and hypotension.

ANTIDOTE

If minor side effects are noted, notify the physician, who may treat the side effects symptomatically and continue the drug. If side effects are progressive or any major side effect occurs, discontinue the drug immediately and notify the physician. Treatment of major side effects is symptomatic and aggressive. Monitor serum electrolytes, carbon dioxide level, and BP frequently, and replace excessive fluid and electrolyte losses as needed. Hemodialysis does not accelerate furosemide elimination. Resuscitate as necessary.

---

(gan-**SYE**-kloh-veer **SO**-dee-um)
Cytovene IV, Ganzyk-RTU
Antiviral
pH 9 to 11, pH 7.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Adequate hydration and specific testing required; see Monitor.

CMV retinitis in adults:

Induction dose: 5 mg/kg of body weight every 12 hours for 14 to 21 days.

Maintenance dose:

Begin a maintenance dose the next day (Day 15 to 22) of 5 mg/kg daily for 7 days each week or 6 mg/kg daily for 5 days each week. See Precautions/Monitor. Do not exceed recommended dose or infusion rate. Larger doses or increased rates of infusion have resulted in increased toxicity. For patients who have relapsed after induction and re-induction monotherapy with either ganciclovir or foscarnet, practitioners may consider an unlabeled combination therapy that adds the alternate drug to the regimen. Information on this combination regimen is available from the manufacturer and in the Clinical Trials section of the foscarnet sodium prescribing information.

Prevention of CMV disease in adult transplant recipients:

Induction dose:

5 mg/kg every 12 hours for 7 to 14 days.

Maintenance dose:

Follow with maintenance regimen of 5 mg/kg once daily for 7 days per week or 6 mg/kg once daily for 5 days per week until 100 to 120 days posttransplantation. CMV disease may occur if treatment is stopped prematurely.

PEDIATRIC DOSE

Safety for use in pediatric patients not established. ■ Use extreme caution; long-term carcinogenicity and reproductive toxicity are probable. Benefit must outweigh risks. See Indications and Maternal/Child.

CMV retinitis in pediatric patients over 3 months of age (unlabeled):

Induction dose:

5 mg/kg of body weight every 12 hours for 14 to 21 days. May be increased to 7.5 mg/kg/dose every 12 hours.

Maintenance dose:

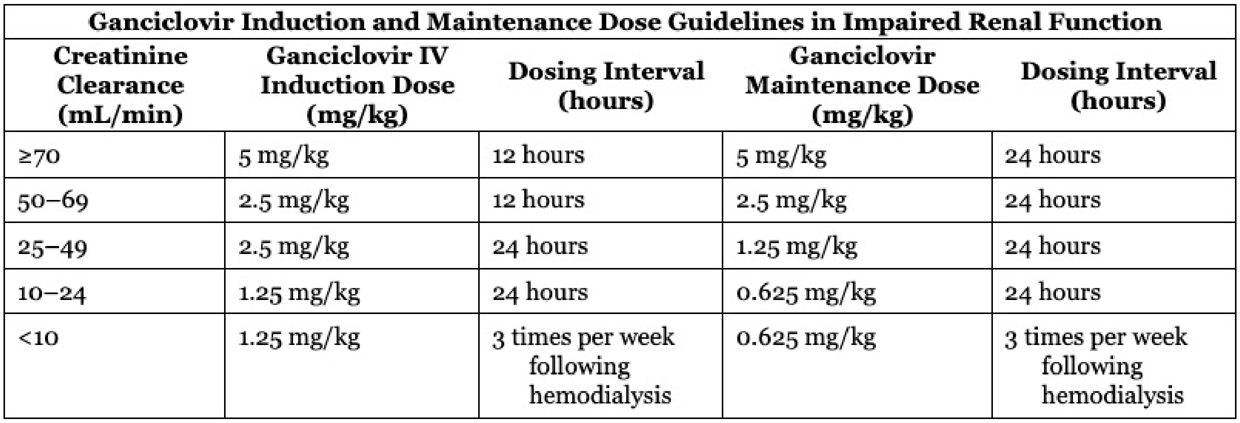
Begin a maintenance dose the next day (Day 15 to 22) of 5 mg/kg daily for 5 to 7 days each week.

Prevention of CMV disease in transplant recipients (unlabeled):

See Usual Dose.

DOSE ADJUSTMENTS

Dose selection should be cautious in elderly patients. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy; see Elderly. ■ Use is not recommended in patients with an absolute neutrophil count (ANC) less than 500 cells/mm^3, hemoglobin less than 8 gm/dL, or platelet count less than 25,000 cells/mm^3. ■ See Drug/Lab Interactions. ■ With impaired renal function, reduce dose according to the following chart.



Ganciclovir Induction and Maintenance Dose Guidelines in Impaired Renal Function

Creatinine Clearance (mL/min)	Ganciclovir IV Induction Dose (mg/kg)	Dosing Interval (hours)	Ganciclovir Maintenance Dose (mg/kg)	Dosing Interval (hours)
≥70	5 mg/kg	12 hours	5 mg/kg	24 hours
50–69	2.5 mg/kg	12 hours	2.5 mg/kg	24 hours
25–49	2.5 mg/kg	24 hours	1.25 mg/kg	24 hours
10–24	1.25 mg/kg	24 hours	0.625 mg/kg	24 hours
<10	1.25 mg/kg	3 times per week following hemodialysis	0.625 mg/kg	3 times per week following hemodialysis

DILUTION

Specific techniques required; see Precautions.

Cytovene IV:

Initially dissolve the 500-mg vial with 10 mL SWFI (50 mg/mL). Do not use bacteriostatic water containing parabens; will cause precipitation. Gently swirl the vial. Continue swirling until a clear reconstituted solution is obtained. Discard if particulate matter or discoloration observed. Withdraw desired dose and further dilute with NS, D5W, Ringer's, or LR to provide a concentration less than 10 mg/mL (70-kg adult at 5 mg/kg equals 350 mg; dissolved in 100 mL of solution equals 3.5 mg/mL).

Ganzyk-RTU:

Premixed, ready-to-use, single-dose polymeric bag containing 500 mg ganciclovir in 250 mL of solution (2 mg/mL).

Filters:

Use not required by manufacturer; however, use of a filter would not have an adverse effect.

Storage:

Cytovene IV:

Store at CRT before use. Reconstituted solution in vial stable at RT (25° C [77° F]) for 12 hours. Do not refrigerate or freeze. Solution fully diluted for administration must be refrigerated at 2° to 8° C (36° to 46° F) and used within 24 hours to reduce incidence of bacterial contamination. Do not freeze.

Ganzyk-RTU:

Store at CRT before use. Discard any unused portion.

COMPATIBILITY

Manufacturer of Ganzyk-RTU states, "Do not add supplemental medication to the intravenous bag."

Because of physical **incompatibilities,** ganciclovir sodium and ***foscarnet sodium*** must never be mixed.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be administered at a constant rate over 1 hour as an infusion, preferably via plastic cannula. ***Do not give by rapid or bolus IV injection.*** Excessive plasma levels and toxicity will occur with a too-rapid rate of injection. Advisable to clear tubing with NS before and after administration through Y-tube or three-way stopcock.

ACTIONS

An antiviral agent with virustatic activity against CMV. Inhibits DNA synthesis and stops cytomegalovirus (CMV) from multiplying. Widely distributed in tissues and body fluids. Crosses the placental barrier. Suspected to be secreted in breast milk. Half-life is 2.6 to 4.4 hours. Approximately 90% excreted unchanged in urine in patients with normal renal function.

INDICATIONS AND USES

Treatment of CMV retinitis in immunocompromised adult individuals, including patients with AIDS. ■ CMV disease prevention in at-risk adult transplant patients.

Unlabeled uses:

Treatment of other CMV infections (e.g., gastroenteritis, hepatitis, pneumonitis) in immunocompromised patients. ■ Combination therapy (ganciclovir and foscarnet) to treat progressive retinitis refractory to single-agent therapy.

CONTRAINDICATIONS

Patients who have experienced a clinically significant hypersensitivity reaction (e.g., anaphylaxis) to ganciclovir, valganciclovir, or any component of the formulation. ■ Use is not recommended in patients with neutrophil count less than 500 cells/mm^3, hemoglobin less than 8 gm/dL, or platelet count less than 25,000 cells/mm^3.

PRECAUTIONS

A nucleoside analog; follow guidelines for handling and disposal of cytotoxic agents. See Appendix A, p. 1308. ■ For IV use only; IM or SC administration will cause severe tissue irritation. ■ Hematologic toxicity (anemia, granulocytopenia, pancytopenia, thrombocytopenia) has been reported; see Monitor. ■ Use with caution in patients with pre-existing cytopenias and in patients receiving myelosuppressive drugs or irradiation. ■ Use with caution in patients with renal impairment. Increased SCr has been reported in elderly patients and in transplant patients receiving concomitant nephrotoxic medications (e.g., cyclosporine and amphotericin B). ■ Ganciclovir is not a cure for CMV infections. Maintenance therapy is almost always necessary to prevent relapse in patients with AIDS. ■ Resistance has been reported to develop. May be higher in patients treated for a prolonged period. The possibility of resistance should be considered in patients who show poor clinical response or experience persistent viral excretion during therapy. ■ May cause temporary or permanent inhibition of spermatogenesis in males and suppression of fertility in females. ■ Based on animal data, has the potential to cause cancer in humans.

Monitor:

Confirm diagnosis of CMV retinitis by indirect ophthalmoscopy. Diagnosis may be supported by cultures of CMV (e.g., urine, blood, throat); negative culture does not rule out CMV retinitis. ■ Continue ophthalmologic exams during induction and maintenance treatment to monitor CMV status. ■ CBC with differential and platelet counts are required before treatment is initiated. ■ Monitor CBC, differential, and platelet counts frequently in all patients, especially in patients who have renal impairment and/or are undergoing hemodialysis, patients who have experienced previous cytopenias from ganciclovir or other nucleoside analogs, or patients who have fewer than 1,000 cells/mm^3 neutrophils at the beginning of treatment. ■ Obtain baseline SCr and CrCl. Monitor during therapy and adjust dose as needed. Monitoring renal function during therapy is essential for all patients but especially for elderly patients and patients receiving concomitant agents that may cause nephrotoxicity. ■

Maintain adequate hydration and urine flow before and during infusion. ■ Phlebitis or pain may occur at site of infusion; confirm patency of vein and use small needles and large veins to ensure adequate blood flow for rapid dilution and distribution. ■ Neutropenia usually occurs during the first or second week of treatment but may occur at any time; recovery should begin within 3 to 7 days of discontinuing ganciclovir. ■ See Drug/Lab Interactions.

Patient Education:

Pregnancy testing required before initiation of treatment in women of childbearing potential, and effective contraception should be used during treatment and for at least 30 days after treatment. Men should use barrier contraception during treatment and for at least 90 days after treatment. ■ May cause temporary or permanent infertility. ■ Not a cure; retinitis may still progress. Frequent ophthalmoscopic examinations are important. ■ Cooperation for close monitoring of blood cell counts and renal function is imperative to control possible side effects (e.g., anemia, neutropenia, thrombocytopenia, increased SCr). ■ Promptly report any unexpected side effects (e.g., chills, fever, unusual bleeding or bruising). ■ Patients with AIDS receiving zidovudine (AZT, Retrovir) may not tolerate ganciclovir. ■ Review all medications (prescription, over the counter, and herbal) with health care provider. ■ Ganciclovir may affect cognitive abilities, including the ability to drive and operate machinery. Seizures, dizziness, and/or confusion have been reported.

Maternal/Child:

Avoid pregnancy. Has the potential to cause birth defects in humans. Do not use during pregnancy unless risk is justified. ■ Breast-feeding is not recommended because of the potential for serious adverse reactions in nursing infants. The CDC recommends HIV-infected mothers not breast-feed to avoid potential postnatal transmission of HIV. ■ Safety and efficacy in pediatric patients have not been established. Long-term carcinogenicity and reproductive toxicity are probable. Benefit must outweigh risks.

Elderly:

Dose selection should be cautious; see Dose Adjustments. Monitor renal function during therapy and adjust dose as indicated.

DRUG/LAB INTERACTIONS

Because of physical **incompatibilities,** ganciclovir and **foscarnet** must never be mixed. ■ Additive toxicity may occur with concurrent or consecutive use with **other bone marrow suppressants** (e.g., dapsone, doxorubicin, flucytosine, hydroxyurea, pentamidine, sulfamethoxazole/trimethoprim, tacrolimus, vinblastine, vincristine, zidovudine. Consider risk versus benefit. ■ May cause severe anemia and neutropenia with **zidovudine**. Combination used in patients with AIDS may not be tolerated. ■ Concurrent treatment with **didanosine** may cause increased didanosine levels. Monitor for didanosine toxicity. ■ May cause seizures with **imipenem-cilastatin**; coadministration not recommended. ■ Potentiated by **probenecid and other drugs that may reduce renal clearance;** monitor for evidence of ganciclovir toxicity. ■ Risk of renal toxicity increased with concurrent use of other **nephrotoxic agents** (e.g., cyclosporine, amphotericin B). Monitor renal function. ■ Increased risk of hematologic and renal toxicity when given concomitantly with **mycophenolate mofetil**. Monitoring required.

SIDE EFFECTS

Abdominal pain, anemia, asthenia, cough, decreased appetite, diarrhea, dyspnea, fever, headache, hyperhidrosis, increased blood creatinine, leukopenia, nausea, and sepsis are most common. Anorexia, chills, infection, neuropathy, neutropenia, pain and infection at injection site, phlebitis, pruritus, rash, retinal detachment, sweating, thrombocytopenia, and vomiting occur in some patients. Hypersensitivity reactions have been reported. Numerous additional side effects may occur.

Overdose:

Abdominal pain, acute renal failure, bone marrow failure, diarrhea, hepatitis, leukopenia, liver function disorder, myelosuppression, seizures, vomiting, and worsening in pre-existing renal impairment have occurred.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Filgrastim has been used to increase the neutrophil count. Hydration and hemodialysis (up to 50% removal) are useful in overdose. Treat anaphylaxis and resuscitate as necessary.

GALLIUM NITRATE BBW

(**GAL**-lee-yum **NIH**-trayt)
Ganite
Antihypercalcemic
pH 6 to 7

USUAL DOSE

Pretreatment:

Adequate hydration and baseline studies required; see Monitor.

Gallium nitrate:

200 mg/M^2 daily for 5 consecutive days. Must be administered as an IV infusion. Discontinue treatment at any time the serum calcium levels are lowered into the normal range (8.5 to 10.5 mg/100 mL, corrected for serum albumin). Safety and effectiveness of retreatment not established. See Precautions.

DOSE ADJUSTMENTS

Consider reduction to 100 mg/M^2/day for 5 days in patients with mild hypercalcemia (12 mg/100 mL range corrected for serum albumin) and few symptoms. ■ Reduced dose may be required in impaired renal function based on CrCl (2 to 2.5 mg/100 mL). See Contraindications.

DILUTION

A single daily dose must be diluted in 1,000 mL NS (preferred) or D5W. Less diluent may be used if absolutely necessary in patients with compromised cardiovascular status.

Filters:

Use not required by manufacturer; however, use of a filter would not have an adverse effect.

Storage:

Store at CRT before dilution. Stable after dilution for 48 hours at CRT and for 7 days if refrigerated.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single daily dose equally distributed over 24 hours as an IV infusion. Use of a microdrip (60 gtt/mL) or an infusion pump recommended for even distribution. Too-rapid injection may lead to overdose.

ACTIONS

A hypocalcemic agent that inhibits calcium resorption from bone. Thought to act by reducing increased bone turnover. Does not have cytotoxic effects on bone cells. Plasma levels achieve a steady state 24 to 48 hours after infusion initiated. In one study it normalized serum calcium in 75% of patients who began treatment with a serum calcium corrected for albumin greater than 12 mg/100 mL. Maintains duration of normocalcemia/hypocalcemia longer than calcitonin. Route of metabolism is unknown. Significant excretion occurs through the kidneys.

INDICATIONS AND USES

Treatment of clearly symptomatic cancer-related hypercalcemia that has not responded to adequate hydration. Serum calcium above 12 mg/100 mL corrected for serum albumin. Symptoms may include anorexia, cardiac arrest, coma, confusion, constipation, dehydration, depression, fatigue, muscle weakness, nausea, and vomiting.

Unlabeled uses:

Slow bone resorption and reduce calcium excretion in bone metastasis; treatment of malignant lymphoma.

CONTRAINDICATIONS

Severe renal impairment (SCr greater than 2.5 mg/100 mL).

PRECAUTIONS

In patients with cancer-related hypercalcemia, the risk of developing severe renal insufficiency is increased with concurrent use of other potentially nephrotoxic drugs (e.g., aminoglycosides [e.g., gentamicin], amphotericin B). If use of these drugs is necessary, discontinue gallium nitrate. Continue hydration for several days after administration of nephrotoxic drugs, and closely monitor serum creatinine and urine output during and after their administration. ■ Calcium is bound to serum protein; concentration fluctuates with changes in blood volume. Changes in serum calcium (especially during rehydration) may not reflect true plasma levels. All calcium measurement should be corrected for albumin to establish a basis for treatment and evaluation of treatment. ■ Mild or asymptomatic hypercalcemia will be treated with conservative measures (e.g., saline hydration, with or without diuretics). Consider patient's cardiovascular status.

Monitor:

Baseline measurements of serum calcium corrected for serum albumin, serum phosphorus, electrolytes, plasma pH, SCr, and BUN are required. Monitor calcium daily, phosphorus twice weekly, and electrolytes, plasma pH, creatinine, and BUN closely as indicated by baseline results (may be daily). ■ Patients with cancer-related hypercalcemia are frequently dehydrated. Must be adequately hydrated orally and/or intravenously before treatment is initiated. Hydration with saline is preferred to facilitate renal excretion of calcium and correct dehydration. A pretreatment urine output of 2 L/day is recommended. ■ Avoid overhydration in patients with compromised cardiovascular status. Observe frequently for signs of fluid overload. Correct hypovolemia before using diuretics. ■ Maintain adequate hydration and urine output throughout treatment. ■ See Precautions.

Patient Education:

Regular visits and assessments of lab tests imperative. ■ Restriction of dietary calcium and vitamin D may be required. ■ Take only prescribed medications. ■ Report abdominal cramps, chills, confusion, fever, muscle spasms, sore throat, and/or any new medical problem promptly.

Maternal/Child:

Category C: use in pregnancy has not been studied; use only if clearly needed. ■ Discontinue breast-feeding or do not use gallium nitrate. Consider importance of drug to mother. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Nephrotoxicity may be increased with **other nephrotoxic drugs** (e.g., aminoglycosides, amphotericin B); see Precautions. ■ Concomitant use with **oral cyclophosphamide and oral prednisone** may cause asthenia, dyspnea, and mouth soreness in a small number of patients with multiple myeloma.

SIDE EFFECTS

Acute renal failure, anemia, asymptomatic decrease in BP, confusion, constipation, diarrhea, dreams and hallucinations, dyspnea, edema of the lower extremities, fever, fluid overload, hearing loss, hypocalcemia, hypophosphatemia, hypothermia, lethargy, leukopenia, nausea and vomiting, optic neuritis (acute), paresthesia, pleural effusion, pulmonary infiltrates, rales and rhonchi, rash, respiratory alkalosis, tinnitus. Many other side effects, possibly from underlying disease, have occurred in less than 1% of patients.

Overdose:

Acute renal failure, anemia, hypocalcemia, hypophosphatemia, nausea, vomiting.

ANTIDOTE

Discontinue drug if CrCl reaches 2.5 mg/100 mL at any time during treatment. Discontinue if concurrent use of nephrotoxic drugs is indicated, and continue hydration for several days after nephrotoxic drug regimen is complete. Discontinue drug for any symptoms of overdose. Monitor serum calcium; use vigorous IV hydration, with or without diuretics, for 2 to 3 days. Monitor intake and output to ensure adequacy and balance. For asymptomatic or mild to moderate hypocalcemia (6.5 to 8 mg/100 mL corrected for serum albumin), short-term calcium therapy may be indicated. Oral phosphorus may be required for hypophosphatemia. RBC transfusions may be required in anemia. Keep physician informed. Some side effects may respond to symptomatic treatment. Treat anaphylaxis and resuscitate as indicated.

GALSULFASE

(gal-**SUL**-face)
Naglazyme
Enzyme replenisher
pH 5.8

USUAL DOSE

Pretreatment:

Evaluate airway patency; see Monitor.

Premedication:

Administration of antihistamines (e.g., diphenhydramine) with or without antipyretics (e.g., acetaminophen) is recommended and should be given 30 to 60 minutes before starting the infusion. All patients in the initial clinical studies were treated with antihistamines.

Galsulfase:

1 mg/kg of body weight as an infusion once each week.

PEDIATRIC DOSE

See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

None indicated.

DILUTION

Prepare diluted solution using low–protein binding container; see Compatibility.

Patients over 20 kg:

Supplied in clear Type 1 glass 5-mL vials; see Compatibility. Each vial contains 5 mg (5 mL) of galsulfase. Determine the number of vials needed to provide the calculated dose. Patient weight in kg equals the dose in mL. Calculate the number of vials needed by dividing the weight in kg by 5 (the number of mg and mL in one vial). For example, a patient weighing 22 kg would receive a 22-mg (mL) dose (22 kg × 1 mg/kg = 22 mg or 22 mL). 22 mg (mL) divided by 5 mg (mL) equals 4.4 vials. Round up to the next whole number, so 5 vials would be required. Handle vials carefully; ***avoid shaking or agitation.*** Before use, remove vials from refrigerator and allow them to reach room temperature; see Storage. Solution in vials should be colorless to pale yellow, clear to slightly opalescent. May have a few translucent particles. ***Do not use a filter needle dur ing any step of the galsulfase dilution process; see*** Filters**.** Must be further diluted in NS to a total volume of 250 mL. From a 250-mL infusion bag of NS, withdraw and discard a volume equal to the total calculated volume of galsulfase to be added (22 mL in the previous example). Next, slowly withdraw the calculated dose of galsulfase from the required vials. Use caution to avoid excessive agitation. Slowly add the galsulfase solution to the NS. Use care to avoid agitation of the solutions. Gently rotate the infusion bag to ensure proper mixing. ***Avoid shaking or agitation.***

Patients 20 kg and under or those who are susceptible to fluid volume overload:

To avoid fluid overload in these patients, galsulfase may be diluted in 100 mL of NS. Withdrawing the calculated volume of drug from the 100 mL NS infusion bag is not indicated; otherwise, the dilution process remains the same.

Filters:

Do not use filter needles; may cause agitation. Agitation may denature galsulfase and render it biologically inactive. ***Fully diluted solution*** should be filtered through an in-line, low–protein-binding, 0.2-micron filter for administration.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46 ° F). Do not use after the expiration date on the vial. ***Do not freeze or shake.*** Protect from light. Immediate use of vials after removal from refrigeration is recommended. Vials must not remain at RT for more than 24 hours before dilution. Do not heat or microwave vials. Immediate use of the diluted solution is preferred; however, if necessary, the diluted solution may be refrigerated. Storage after dilution must not exceed 48 hours from time of preparation to completion of administration. For single use only in vials or solution; discard unused drug.

COMPATIBILITY

Manufacturer states, “Must not be infused with other products in the infusion tubing.” Use of low–protein binding containers and infusion sets recommended; **compatibility** with glass containers not established.

RATE OF ADMINISTRATION

Fully diluted solution should be administered with a low–protein binding infusion set equipped with an in-line, low–protein binding, 0.2-micron filter. Infusion reactions may occur even when patients have been premedicated. Administration as a controlled IV infusion using an infusion pump is recommended.

Initial infusion rate for solutions diluted in 250 mL NS:

6 mL/hr for the first hour. Should an infusion reaction occur, further decrease this rate or discontinue infusion until symptoms subside. Additional premedication may be indicated. If the infusion is well tolerated, the rate may be increased to 80 mL/hr for the remaining 3 hours. Infusion must be distributed over a minimum of 4 hours but may be extended up to 20 hours if an infusion reaction occurs.

Initial infusion rate for solutions diluted in 100 mL NS:

Decrease initial and subsequent rates given for solutions diluted in 250 mL NS by approximately one half or less (2 to 3 mL/hr initially). Should an infusion reaction occur, further decrease this rate or discontinue infusion until symptoms subside. Additional premedication may be indicated. If the infusion is well tolerated, the rate may be increased to equally distribute the remaining solution over the remaining 3 hours. Infusion must be distributed over a minimum of 4 hours but may be extended up to 20 hours if an infusion reaction occurs.

ACTIONS

A formulation of galsulfase, which is a purified human enzyme produced by recombinant DNA technology. Mucopolysaccharide storage disorders are caused by the deficiency of specific lysosomal enzymes required for the catabolism of glycosaminoglycans (GAG). A deficiency of sulfatase activity results in the accumulation of the GAG substrate, dermatan sulfate, throughout the body. This accumulation leads to widespread cellular, tissue, and organ dysfunction. Galsulfase provides an exogenous enzyme for uptake into lysosomes and increases the catabolism of GAG. Has been shown to improve walking and stair-climbing ability. Mean half-life is 9 minutes (range from 6 to 21 minutes) after 1 week and increases to 26 minutes (range 8 to 40 minutes) by 24 weeks of treatment. Bioactivity can be evaluated with urinary GAG concentrations. Urinary GAG concentrations decrease in patients receiving galsulfase; however, normal urinary GAG concentrations have not been achieved.

INDICATIONS AND USES

For patients with mucopolysaccharidosis VI (MPS VI, Maroteaux-Lamy syndrome). Has been shown to improve walking and stair-climbing capacity. Reduces the accumulation of a specific GAG substrate, dermatan sulfate, throughout the body, which leads to widespread cellular, tissue, and organ dysfunction in patients with mucopolysaccharidosis VI.

CONTRAINDICATIONS

Manufacturer states, "None known."

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with facilities for monitoring the patient and responding to any medical emergency. ■ Infusion reactions, some severe, may occur even in patients who have been appropriately premedicated. ■ Patients with MPS VI may have a pre-existing upper airway obstruction, are prone to sleep apnea, and may be at increased risk for apneic episodes; monitor closely. ■ Severe hypersensitivity reactions have been observed during and up to 24 hours after galsulfase infusion. Some were life threatening and included anaphylaxis, bronchospasm, dyspnea, hypotension, laryngeal edema, respiratory distress, and shock. If a severe hypersensitivity or anaphylactic reaction occurs, consider risk versus benefit before resuming therapy or considering additional infusions. ■ Type III immune complex–mediated reactions, including membranous glomerulonephritis, have been observed. Consider risks and benefits of readministering galsulfase. Some patients have been rechallenged with close clinical supervision. ■ Use caution in patients susceptible to fluid volume overload, such as patients weighing 20 kg or less, patients with acute underlying respiratory illness, or patients with compromised cardiac and/or respiratory function. May result in CHF. ■ Spinal or cervical cord compression (SCC) with resultant myelopathy is a known and serious complication of MPS VI. There have been post-marketing reports of patients treated with galsulfase who experienced the onset or worsening of SCC, requiring decompression surgery. ■ Most patients develop antibodies to galsulfase; their effects on therapy are not known. No association between the titer of anti-galsulfase antibodies and the severity of infusion reactions or urinary GAG levels has been observed.

Monitor:

Monitor V/S frequently. ■ Evaluate airway patency before initiating treatment with galsulfase. ■ Patients using supplemental oxygen or continuous positive airway pressure (CPAP) during sleep should have these treatments readily available during infusion. May be required if an infusion reaction occurs or if extreme drowsiness or sleep is induced by antihistamine use. ■ Observe patients continuously for symptoms of infusion-related or hypersensitivity reactions. Initial infusion reactions can occur at any time during treatment, even in patients who have not had reactions with previous injections (occurred up to 146 weeks into treatment). Abdominal pain, chills/rigors, dyspnea, erythema, fever, headache, hypertension, nausea, pruritus, rash, urticaria (mild to moderate), and vomiting are most common. Severe symptoms may include apnea, bronchospasm, chest pain, conjunctivitis, dyspnea, hypotension, laryngeal edema, rash, respiratory distress, and urticaria. ■ Monitor patients with compromised cardiac or respiratory function closely; may be at risk for serious acute exacerbation of their cardiac or respiratory compromise due to infusion, hypersensitivity, or immune-mediated reactions. Prolonged observation times may be required. ■ Monitor for S/S of SCC (e.g., back pain, paralysis, urinary and fecal incontinence). ■ See Precautions and Antidote. Numerous other baseline tests and specific monitoring of airway, cardiac, circulatory, and renal functions may be indicated based on the degree of progression of each patient's MPS VI. Urinary GAG levels, distance walked, and rate of stair climbing were measured in clinical studies.

Patient Education:

Report promptly early symptoms of hypersensitivity or infusion reactions (e.g., chills or rigors, fever, flushing, headache, itching, rash, shortness of breath). ■ BioMarin has established a registry and encourages all patients to participate to further evaluate the effects of therapy with possible long-term follow-up.

Maternal/Child:

Category B: use during pregnancy only if clearly needed. No evidence of impaired fertility or harm to the fetus in animal studies with rats; see registry information in Patient Education. ■ Effects during breast-feeding unknown; use caution; see registry information in Patient Education. ■ Clinical studies were conducted in 56 patients 5 to 29 years of age, with the majority of these patients in the pediatric age-group. An open-label study was conducted in four infants (3 to 12.7 months of age) treated with 1 mg/kg or 2 mg/kg of galsulfase. Safety results were consistent with those observed in patients 5 to 29 years of age.

Elderly:

Patients older than 29 years of age were not included in studies; response in elderly unknown. Consider limited life expectancy of patients with MPS VI.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

Infusion-related reactions occur frequently. Anaphylaxis, angioedema, apnea, fever, laryngeal edema, respiratory distress, and urticaria have been reported and may be life threatening. Abdominal pain, chills/rigors, dyspnea, erythema, fever, headache, nausea, pain, pruritus, rash, urticaria (mild to moderate), and vomiting are most common. Severe symptoms may include apnea, bronchospasm, chest pain, conjunctivitis, hypotension, rash, and respiratory distress. Areflexia (absence of reflexes), arthralgia, cough, ear pain, gastroenteritis, hearing impairment, hypertension, increased corneal opacification, malaise, nasal congestion, pharyngitis, respiratory infections, and umbilical hernia have been reported.

Post-Marketing:

Anaphylaxis, bradycardia, bronchospasm, cyanosis, hypotension, hypoxia, membranous nephropathy, pallor, paresthesia, respiratory failure, shock, spinal or cervical cord compression, tachycardia, tachypnea, thrombocytopenia.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. If a severe hypersensitivity or anaphylactic reaction occurs, discontinue galsulfase immediately and treat as indicated. If a mild to moderate infusion or hypersensitivity reaction occurs, reduce rate or discontinue galsulfase until symptoms subside. Additional antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen) may be indicated. Treatment with and/or premedication with corticosteroids (e.g., dexamethasone) may be indicated based on the severity of infusion reactions. With additional premedication and/or a reduction in the rate of infusion, patients may be able to continue treatment. If an immune-mediated reaction occurs, discontinue galsulfase and initiate appropriate medical treatment. Resuscitate as necessary.

GEMCITABINE HYDROCHLORIDE

(jem-**SIGHT**-ah-been hy-droh-**KLOR**-eyed)
Gemzar, Infugem
Antineoplastic (miscellaneous)
pH 2.7 to 3.3

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor. Review monographs of indicated antineoplastics that are to be used in combination with gemcitabine for additional information.

Pancreatic cancer:

1,000 mg/M^2 as outlined in the following treatment schedule:

Weeks 1-8:

Weekly dosing for the first 7 weeks followed by 1 week of rest.

After Week 8:

Weekly dosing on Days 1, 8, and 15 of 28-day cycles.

Non–small-cell lung cancer (NSCLC):

1,000 mg/M^2 as an infusion on Days 1, 8, and 15 of each 28-day cycle. Given in combination with cisplatin. Administer cisplatin 100 mg/M^2 IV on Day 1 after the infusion of gemcitabine. An alternate schedule is gemcitabine 1,250 mg/M^2 on Days 1 and 8 of each 21-day cycle. Administer cisplatin 100 mg/M^2 IV on Day 1 after the infusion of gemcitabine.

Breast cancer:

1,250 mg/M^2 as an infusion on Days 1 and 8 of each 21-day cycle. Given in combination with paclitaxel. On Day 1, administer paclitaxel 175 mg/M^2 as a 3-hour infusion before the gemcitabine infusion.

Ovarian cancer:

1,000 mg/M^2 as an infusion on Days 1 and 8 of a 21-day cycle. Given in combination with carboplatin. On Day 1 of the 21-day cycle, administer carboplatin at AUC 4 after gemcitabine administration.

Bladder cancer (unlabeled):

1,000 mg/M^2 on Days 1, 8, and 15. Repeat cycle every 28 days. Given in conjunction with cisplatin. Alternatively, 1,000 mg/M^2 on Days 1 and 8. Repeat cycle every 21 days. Given in combination with carboplatin.

Hodgkin lymphoma (relapsed) or non-Hodgkin lymphoma (refractory) (unlabeled):

1,000 mg/M^2 on Days 1 and 8 of a 21-day cycle. Given in combination with other agents.

Head and neck cancer (unlabeled):

1,000 mg/M^2 on Days 1, 8, and 15 every 28 days or 1,000 mg/M^2 on Days 1 and 8 every 21 days. Given in combination with vinorelbine.

Adenocarcinoma of the pancreas:

Given in combination with Abraxane; see paclitaxel protein-bound particles for injectable suspension monograph.

DOSE ADJUSTMENTS

Clearance decreased in women and the elderly. May be less likely to progress to subsequent cycles; see Precautions and Elderly.

Gemcitabine Dose Modifications for Nonhematologic Adverse Reactions

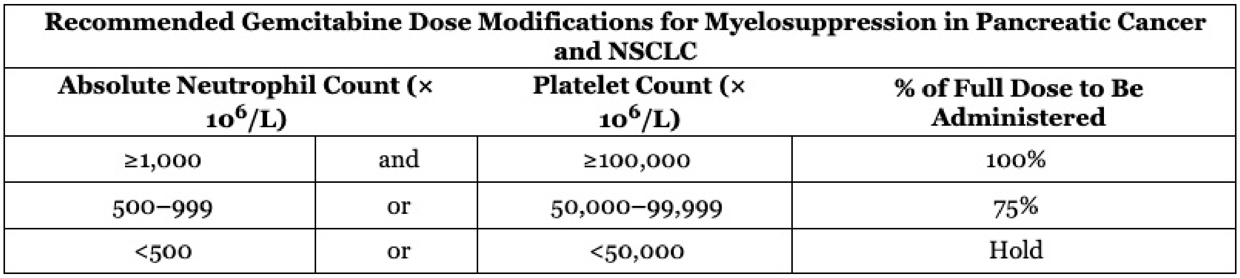
Permanently discontinue gemcitabine for any of the following:

- Unexplained dyspnea or other evidence of severe pulmonary toxicity
- Severe hepatic toxicity
- Hemolytic-uremic syndrome (HUS) or severe renal impairment
- Capillary leak syndrome (CLS)
- Posterior reversible encephalopathy syndrome (PRES)
- Withhold gemcitabine or reduce dose by 50% for other severe (Grade 3 or 4) nonhematologic toxicity until resolved

Gemzar: No dose modifications are recommended for alopecia, nausea, or vomiting.

Treatment of pancreatic cancer and NSCLC:

Reduce dose based on the degree of hematologic toxicity according to the following chart.

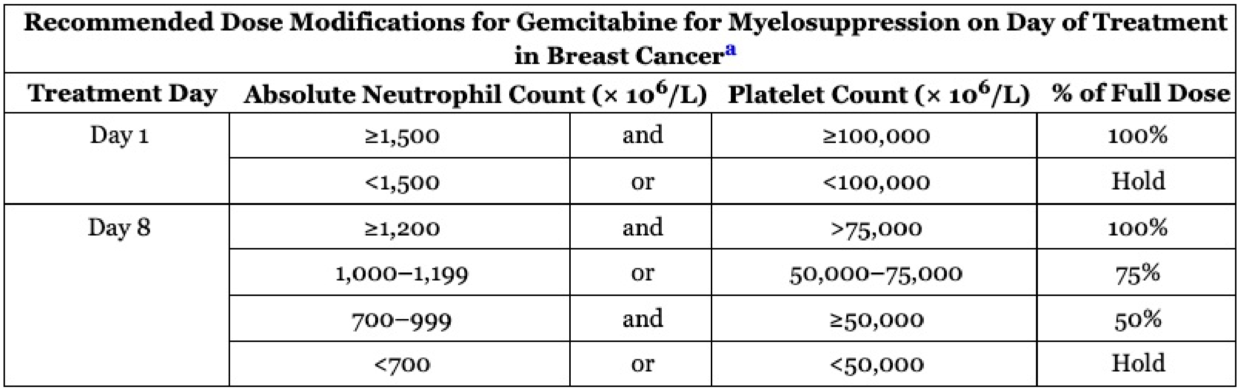


Recommended Gemcitabine Dose Modifications for Myelosuppression in Pancreatic Cancer and NSCLC

Absolute Neutrophil Count (× 10^6/L)		Platelet Count (× 10^6/L)	% of Full Dose to Be Administered
≥1,000	and	≥100,000	100%
500–999	or	50,000–99,999	75%
<500	or	<50,000	Hold

Treatment of breast cancer (combination with paclitaxel):

Reduce dose based on degree of hematologic toxicity according to the following chart.



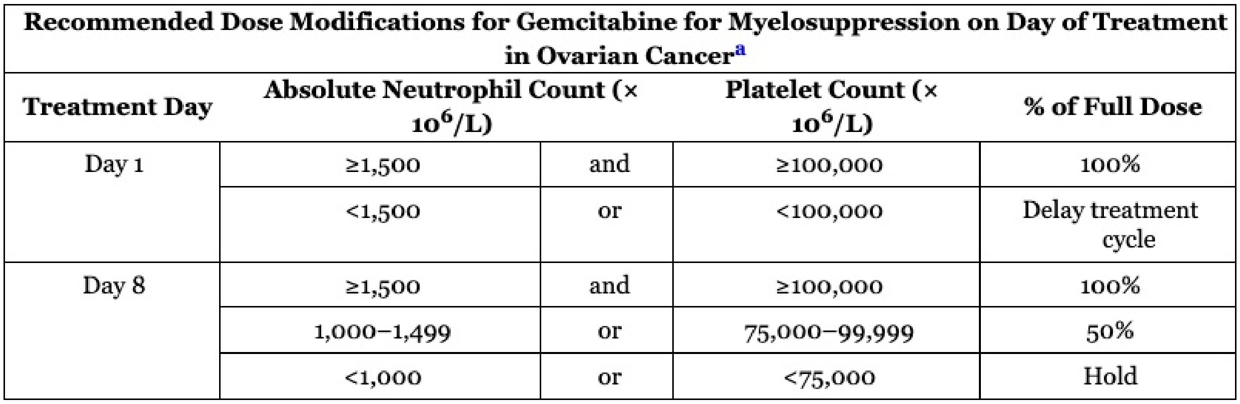
Recommended Dose Modifications for Gemcitabine for Myelosuppression on Day of Treatment in Breast Cancer[a]

Treatment Day	Absolute Neutrophil Count (× 10^6/L)		Platelet Count (× 10^6/L)	% of Full Dose
Day 1	≥1,500	and	≥100,000	100%
	<1,500	or	<100,000	Hold
Day 8	≥1,200	and	>75,000	100%
	1,000–1,199	or	50,000–75,000	75%
	700–999	and	≥50,000	50%
	<700	or	<50,000	Hold

[a] See paclitaxel monograph for additional dose adjustment guidelines.

Treatment of ovarian cancer in combination with carboplatin:

Reduce dose based on the degree of hematologic toxicity according to the following charts.

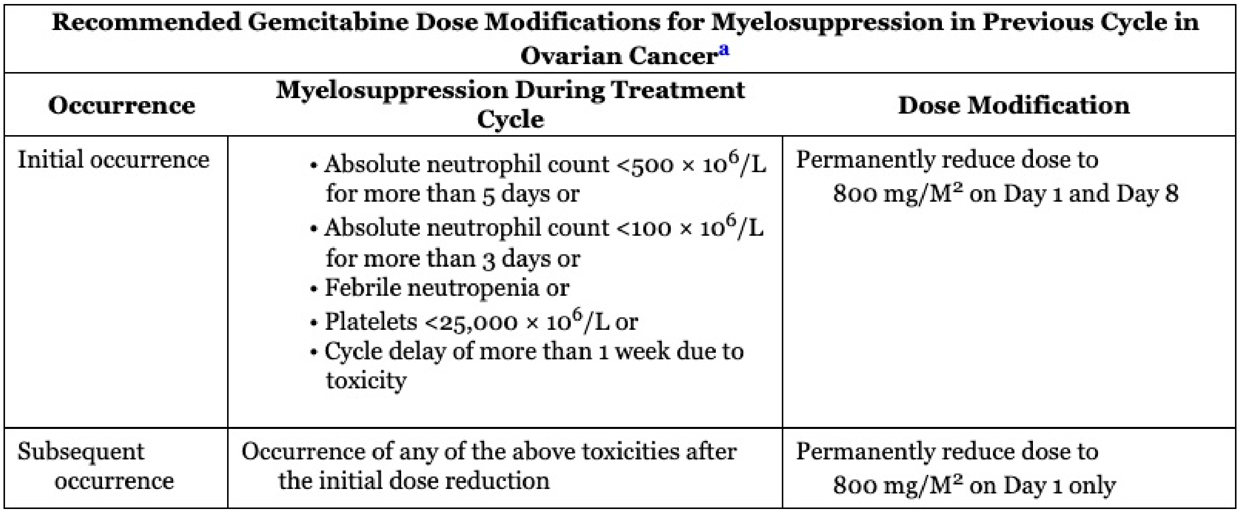


Recommended Dose Modifications for Gemcitabine for Myelosuppression on Day of Treatment in Ovarian Cancer[a]				
Treatment Day	**Absolute Neutrophil Count (× 10^6/L)**		**Platelet Count (× 10^6/L)**	**% of Full Dose**
Day 1	≥1,500	and	≥100,000	100%
	<1,500	or	<100,000	Delay treatment cycle
Day 8	≥1,500	and	≥100,000	100%
	1,000–1,499	or	75,000–99,999	50%
	<1,000	or	<75,000	Hold

[a]See carboplatin monograph for additional dosing guidelines.

Gemcitabine dose modification for myelosuppression in previous cycle in ovarian cancer:

Reduce dose based on myelosuppression occurrence according to the following chart:



Recommended Gemcitabine Dose Modifications for Myelosuppression in Previous Cycle in Ovarian Cancer[a]		
Occurrence	**Myelosuppression During Treatment Cycle**	**Dose Modification**
Initial occurrence	• Absolute neutrophil count <500 × 10^6/L for more than 5 days or • Absolute neutrophil count <100 × 10^6/L for more than 3 days or • Febrile neutropenia or • Platelets <25,000 × 10^6/L or • Cycle delay of more than 1 week due to toxicity	Permanently reduce dose to 800 mg/M^2 on Day 1 and Day 8
Subsequent occurrence	Occurrence of any of the above toxicities after the initial dose reduction	Permanently reduce dose to 800 mg/M^2 on Day 1 only

[a]See carboplatin monograph for additional dosing guidelines.

DILUTION

Specific techniques required; see *Precautions*. *Gemzar:*

Available in single-use vials containing 200 mg or 1 Gm of gemcitabine. A white to off-white lyophilized powder. Each 200 mg must be reconstituted with 5 mL NS without preservatives (25 mL NS for 1 Gm). Yields 38 mg/mL. Shake to dissolve. Do not use less solution to reconstitute; dissolution will be incomplete. The appropriate dose ***must*** be further diluted with NS to concentrations as low as 0.1 mg/mL. 1,500 mg diluted in 250 mL yields 6 mg/mL. 750 mg in 100 mL yields 7.5 mg/mL.

Infugem:

Provided in premixed bags (10 mg/mL) that are ready for infusion and do not require any further preparation before use. Do not dilute before use. Do not remove or add medication. Infugem is a clear, colorless solution. Check for leaks by squeezing inner bag firmly. If leaks are found, discard the bag. Select the gemcitabine premixed bag(s) that allow for a variance of up to 5% of the BSA-calculated dose for all indications. See manufacturer's prescribing information for charts showing specific size of infusion bags to use based on BSA range.

Filters:

Specific information not available.

Storage:

Gemzar:

Store unopened vials at CRT. Reconstituted or diluted solutions are stable at CRT for 24 hours. Do not refrigerate in any form; may crystallize. Discard unused portion.

Infugem:

Unopened infusion bags are stable until the expiration date on the package when stored at RT. Do not freeze, as crystallization can occur.

COMPATIBILITY

Gemzar:

Manufacturer states, "No **incompatibilities** observed with IV bottles or PVC bags and administration sets."

Infugem:

Manufacturer states, "Do not remove or add medication."

Other sources suggest **compatibilities** for Gemzar dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Gemzar:

A single dose as an infusion equally distributed over 30 minutes.

Infugem:

Infuse all doses of gemcitabine over 30 minutes. If two premixed infusion bags are required to achieve the prescribed dose, infuse the total volume of both bags over 30 minutes.

Gemzar and Infugem:

Do not extend infusion time beyond 60 minutes; will increase toxicity.

ACTIONS

A nucleoside metabolic inhibitor with antineoplastic activity. Metabolized intracellularly to two active nucleosides. Cell phase specific, these nucleosides induce internucleosomal DNA fragmentation, primarily killing cells undergoing DNA synthesis (S-phase) and also blocking the progression of cells through the G_1/S-phase boundary. Very little is bound to plasma protein. Volume of distribution is increased by infusion length. Half-life is shorter (42 to 94 minutes) with a short infusion (less than 70 minutes), and longer (245 to 638 minutes) with a long infusion (more than 70 minutes). Half-life is slightly longer and rate of clearance is lower in women and in the elderly, resulting in higher concentrations for any given dose. Primarily excreted in urine.

INDICATIONS AND USES

First-line treatment for patients with locally advanced (nonresectable Stage II or Stage III) or metastatic (Stage IV) adenocarcinoma of the pancreas in patients previously treated with fluorouracil. ■ First-line treatment in combination with cisplatin for the treatment of inoperable, locally advanced (Stage IIIA or IIIB) or metastatic (Stage IV) non–small-cell lung cancer. ■ First-line treatment in combination with paclitaxel for treatment of metastatic breast cancer after failure of previous anthracycline chemotherapy unless anthracyclines (e.g., doxorubicin [Adriamycin], idarubicin [Idamycin]) were clinically contraindicated. ■ Treatment in combination with carboplatin for patients with advanced ovarian cancer that has relapsed at least 6 months after completion of platinum-based therapy.

Unlabeled uses:

Treatment of metastatic bladder cancer. ■ Treatment of testicular cancer. ■ Treatment of cancer of the head and neck. ■ Treatment of Hodgkin lymphoma (relapsed) or non-Hodgkin lymphoma (refractory).

CONTRAINDICATIONS

Hypersensitivity to gemcitabine or any of its components.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available. ■ For IV use only. May be administered on an outpatient basis. ■ Prolongation of the infusion time beyond 60 minutes and more frequent than weekly dosing have been shown to increase toxicity (e.g., clinically significant hypotension, severe flu-like symptoms, myelosuppression, and asthenia). ■ Myelosuppression (e.g., anemia, neutropenia, and thrombocytopenia) is the dose-limiting toxicity. Occurs with gemcitabine as a single agent, and the risk increases when it is combined with other cytotoxic drugs; see Dose Adjustments. ■ Clearance in women and the elderly is reduced; women, especially older women, were more likely not to proceed to a subsequent cycle and to experience Grade 3 or 4 neutropenia and thrombocytopenia. No age or gender dose adjustments recommended. ■ Use with caution in impaired renal or hepatic function. Clear dose recommendations are not available; data from clinical studies insufficient. ■ Hepatotoxicity, including liver failure and death, has been reported. Use in patients with concurrent liver metastases or a history of alcoholism, hepatitis, or liver cirrhosis may lead to exacerbation of the underlying hepatic insufficiency. ■ Hemolytic-uremic syndrome (HUS) and/or renal toxicity, including renal failure leading to death or requiring dialysis, has been reported. Serious cases of thrombotic microangiopathy other than HUS have been reported. ■ Gemcitabine is a potent radiosensitizer. Concurrent use of gemcitabine with radiation therapy (or using 7 or fewer days apart from radiation therapy) may cause severe, life-threatening mucositis, especially esophagitis and pneumonitis. Data suggest that gemcitabine can be administered if given more than 7 days before or after radiation therapy. Radiation recall has been reported in patients who receive gemcitabine after prior radiation. ■ Pulmonary toxicity (e.g., adult respiratory distress syndrome [ARDS], interstitial pneumonitis, pulmonary edema, pulmonary fibrosis) has been reported. Fatalities have occurred. Onset of pulmonary symptoms may occur up to 2 weeks after the last dose of gemcitabine. Discontinue gemcitabine in patients who develop unexplained dyspnea, with or without bronchospasm, or who have any evidence of pulmonary toxicity. ■ Capillary leak syndrome (CLS) and posterior reversible encephalopathy syndrome (PRES) have been reported. ■ Use caution in patients who have had previous cytotoxic chemotherapy or radiation therapy.

Monitor:

Monitor for bone marrow suppression. Obtain a CBC, including differential and platelet count, before each dose; see Dose Adjustments. ■ Obtain baseline renal function (e.g., SCr) and liver function tests (e.g., AST, ALT) and repeat periodically. ■ Monitor serum calcium, magnesium, potassium, and SCr during combination therapy with cisplatin. ■ Monitor vital signs. ■ Monitor respiratory status. ■ Maintain adequate hydration. ■ Nausea and vomiting are frequent and were severe in 15% of patients; prophylactic administration of antiemetics will increase patient comfort. ■ Observe closely for S/S of infection. May cause fever in the absence of infection, or prophylactic antibiotics may be indicated pending results of C/S in a febrile or nonfebrile patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Consider a diagnosis of HUS if anemia with evidence of microangiopathic hemolysis, elevation of bilirubin or LDH, reticulocytosis, severe thrombocytopenia, and/or evidence of renal failure (elevation of SCr or BUN) develops; discontinue gemcitabine. ■ Monitor for S/S of CLS (sudden edema, rapid drop in blood pressure, shock, hemoconcentration, hypoalbuminemia). ■ Monitor for S/S of PRES (blindness, confusion, headache, hypertension, lethargy, seizure, or other visual or neurologic disturbances). Confirm diagnosis of PRES with MRI. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation.

Patient Education:

Effective birth control is recommended for females of reproductive potential and males with female partners of reproductive potential during and for 6 months (females) and for 3 months (males) after the last dose of gemcitabine. ■ May impair fertility in males of reproductive potential. ■ Report any unusual or unexpected symptoms or side effects (e.g., shortness of breath, cough, wheezing, blood in stool or urine, change in color or volume of urine, S/S of infection, jaundice, pain/tenderness in the right upper abdominal quadrant, unusual bruising or bleeding) as soon as possible. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. May cause fetal harm. ■ Discontinue breast-feeding during treatment and for at least 1 week after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Clearance reduced in the elderly; hematologic toxicity requiring reduction, delay, or omission of subsequent doses is higher than in younger adults; however, incidence of nonhematologic toxicity is similar. Elderly men and women are more likely to experience Grade 3 or 4 thrombocytopenia. Elderly women are also more likely to experience Grade 3 or 4 neutropenia. Usual dose adjustments based on toxicity are considered appropriate. Age-related impaired renal function may further reduce clearance and increase toxicity.

DRUG/LAB INTERACTIONS

Interaction of gemcitabine with other drugs has not been adequately studied. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

The most common side effects are anemia, dyspnea, fever, hematuria, increased alkaline phosphatase, AST and ALT, nausea, neutropenia, peripheral edema, proteinuria, rash, thrombocytopenia, and vomiting. Less frequently reported side effects include alopecia, anorexia, arthralgia, bone marrow toxicity (e.g., anemia, leukopenia, neutropenia, thrombocytopenia), bone pain, bronchospasm, cerebrovascular accident, constipation, diarrhea, edema, elevated lab tests (e.g., BUN, creatinine, hematuria, proteinuria), fatigue, febrile neutropenia, flu syndrome (e.g., anorexia, chills, cough, headache, myalgia, weakness), hemorrhage, hepatotoxicity, hypertension, increased liver function tests (e.g., ALT, AST, GGT, alkaline phosphatase, and bilirubin), infection, injection site reaction, myalgia, neuropathy (motor and sensory), pain, paresthesias, pruritus, pulmonary toxicity (including respiratory failure), radiation recall reactions, somnolence, and stomatitis. Anaphylaxis and hemolytic-uremic syndrome have been reported.

Post-Marketing:

Adult respiratory distress syndrome (ARDS), arrhythmias, capillary leak syndrome, cellulitis, congestive heart failure, gangrene, hepatic failure, hepatic veno-occlusive disease, interstitial pneumonitis, myocardial infarction, peripheral vasculitis, posterior reversible encephalopathy syndrome (PRES), pulmonary edema, pulmonary eosinophilia, pulmonary fibrosis, pseudocellulitis, severe skin reactions (including desquamation and bullous skin eruptions), supraventricular arrhythmias, and thrombotic microangiopathy (TMA).

ANTIDOTE

Keep physician informed of all side effects. Symptomatic and supportive treatment is indicated. Permanently discontinue gemcitabine if any of the following occur: unexplained dyspnea or other evidence of severe pulmonary toxicity, severe hepatic toxicity, hemolytic uremic syndrome or severe renal impairment, capillary leak syndrome, or posterior reversible encephalopathy syndrome (PRES). Reduce dose or withhold gemcitabine until myelosuppression improves to specific criteria; see Dose Adjustments. Anemia may require RBC transfusions. Other whole blood products (e.g., platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Most side effects are reversible with dose reduction or temporary withholding of gemcitabine. No known antidote for overdose. If hemolytic-uremic syndrome occurs, discontinue gemcitabine; renal failure may not be reversible even with discontinuation of therapy, and dialysis may be required. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine).

GENTAMICIN SULFATE BBW

(jen-tah-**MY**-sin **SUL**-fayt)
Antibacterial (aminoglycoside)
pH 3 to 5.5

USUAL DOSE

Pretreatment:

See Monitor and Maternal/Child.

Gentamicin:

3 mg/kg of body weight/24 hr equally divided into 3 doses (1 mg/kg every 8 hours). Reduce to usual dose as soon as feasible. Another source suggests 1 to 2.5 mg/kg/dose every 8 to 12 hours. A loading dose of 2 mg/kg is commonly used. Gentamicin can also be dosed as 5 to 7 mg/kg/day. **Dosage based on ideal body weight.** Studies suggest that in certain populations a single daily dose of 4 to 7 mg/kg (instead of divided into 2 to 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See Dose Adjustments and Precautions/Monitor.

Prevention of bacterial endocarditis in dental, respiratory tract, GI or GU tract surgery or instrumentation:

1.5 mg/kg 30 minutes before procedure. Do not exceed 80 mg. Repeat in 8 hours. Given concurrently with ampicillin, vancomycin, or amoxicillin.

Pelvic inflammatory disease:

2 mg/kg as an initial dose. Follow with 1.5 mg/kg every 8 hours for 4 days or 48 hours after patient improves. Given concurrently with clindamycin.

PEDIATRIC DOSE

See Maternal/Child.

6 to 7.5 mg/kg of body weight/24 hr (2 to 2.5 mg/kg every 8 hours). A single daily dose is also being used in pediatric patients. See comments under Usual Dose. 10 mg/mL product available for pediatric use.

Prevention of bacterial endocarditis in dental, respiratory tract, GI or GU tract surgery or instrumentation:

2 mg/kg. See Usual Dose for instructions.

NEONATAL DOSE

See Maternal/Child.

2.5 mg/kg. Intervals adjusted based on age as follows:

0 to 7 days of age; less than 28 weeks' gestation: Every 24 hours.
  28 to 34 weeks' gestation: Every 18 hours.
  Over 34 weeks' gestation: Every 12 hours.
Over 7 days of age; less than 28 weeks' gestation: Every 18 hours.
  28 to 34 weeks' gestation: Every 12 hours.
  Over 34 weeks' gestation: Every 8 hours.

Another source suggests that higher doses (4 to 5 mg/kg/dose) at extended intervals (24 to 48 hours) may be used.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment. Other protocols are in use; see literature. ■ Once-daily dosing is not usually used for patients with ascites, burns covering more than 20% of the total body surface area, CrCl less than 40 mL/min (including patients requiring dialysis), CrCl greater than 120 mL/min, cystic fibrosis, endocarditis, mycobacterium infections, or in infants or during pregnancy. ■ Reduced dose or extended intervals may be indicated in elderly adults. Dosing and dose adjustments are generally done by hospital pharmacists. ■ See Monitor and Drug/Lab Interactions.

The recommended dose at the end of each dialysis period is 1 to 1.7 mg/kg depending on the severity of the infection. 2 mg/kg may be administered to pediatric patients. The amount of gentamicin removed by dialysis may vary; however, an 8-hour dialysis session may reduce serum concentrations by 50%.

High-dose therapy:

Interval may be extended (e.g., every 48 hours) in patients with moderate renal impairment (CrCl 30 to 59 mL/min) and/or adjusted based on serum level determinations.

DILUTION

Available premixed in several concentrations. Vials equal 10 or 40 mg/mL. Further dilute each single dose in 50 to 200 mL of IV NS or D5W. Decrease volume of diluent for pediatric patients. Commercially diluted solutions available.

COMPATIBILITY

Manufacturer states, "Do not physically premix with other drugs; administer separately." Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities.** See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each single dose, properly diluted, over 30 to 60 minutes, up to 2 hours in pediatric patients. Studies suggest bolus dosing (versus infusion over 30 minutes) may produce an earlier bactericidal effect, which is sustained. No dose, dilution, or rate recommendations are available at this time.

ACTIONS

Aminoglycoside antibiotic with neuromuscular blocking action. Bactericidal against specific gram-negative bacilli, including *Escherichia coli, Klebsiella, Proteus,* and *Pseudomonas*. Not effective for fungi or viral infections. Well distributed throughout all body fluids; serum and urine levels remain adequate for 6 to 12 hours. Usual half-life is 2 hours. Half-life prolonged in infants, postpartum females, fever, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly; shorter in severe burns. Crosses placental barrier. Excreted through kidneys.

INDICATIONS AND USES

Treatment of serious infections of the GI (peritonitis), respiratory, and urinary tracts; CNS (meningitis); skin; bone; soft tissue (burns); septicemia; and bacterial neonatal sepsis. ■ Primarily used when penicillin and other less toxic antibiotics are ineffective or contraindicated. ■ Prevention of bacterial endocarditis in dental, respiratory tract, GI, or GU surgery or instrumentation. ■ Used concurrently with clindamycin to treat pelvic inflammatory disease. ■ Considered initial therapy after culture and sensitivity is drawn in suspected or confirmed gram-negative infections or other serious infections. ■ Treat suspected infection in the immunosuppressed patient. ■ May be used synergistically in gram-positive infections. ■ Used concurrently with penicillin for endocarditis and neonatal sepsis.

CONTRAINDICATIONS

Known gentamicin or aminoglycoside sensitivity, renal failure. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of the causative organism to gentamicin. ■ Use extreme caution if therapy is required over 7 to 10 days. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Use caution in infants, children, and the elderly. ■ Advanced age and dehydration may increase risk of toxicity. ■ May contain sulfites; use caution in patients with asthma. ■ Aminoglycosides are nephrotoxic; risk for nephrotoxicity is increased in patients with impaired renal function and in patients who receive high doses or prolonged therapy. ■ Use extreme caution in patients with end-stage renal disease. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa,* endocarditis, meningitis, during pregnancy, or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, cystic fibrosis, elderly, pediatrics, renal impairment). ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk of neurotoxicity (e.g., auditory and vestibular ototoxicity) is increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after gentamicin is discontinued. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with gentamicin.

Monitor:

Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations. Therapeutic level is between 4 and 8 mcg/mL. Avoid trough levels above 2 mcg/mL and prolonged peak levels above 12 mcg/mL; adjust dose as indicated. Risk of renal and eighth cranial nerve toxicity increased. Monitor frequently in patients with impaired renal function. ■ Watch for decrease in urine output and rising BUN and SCr. May require decreased dose. ■ Routine gentamicin serum levels and evaluation of hearing are recommended. ■ Closely monitor renal and eighth cranial nerve function, especially in patients with known or suspected reduced renal function at onset of therapy and in patients who develop signs of renal dysfunction during therapy. Monitor urine for decreased specific gravity, increased protein, and the presence of cells or casts. Serial audiograms are recommended, particularly in high-risk patients. ■ Maintain good hydration. ■ Monitor serum calcium, magnesium, sodium, and potassium; levels may decline. Depressed levels have caused mental confusion, paresthesia, positive Chvostek and Trousseau signs (provoked spasm of facial muscles and other muscles; occurs in tetany), and tetany in adults; muscle weakness and tetany in infants. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity, convulsions, muscle twitching, numbness, tingling); nephrotoxicity may be reversible. ■ In extended treatment, daily monitoring of serum levels, electrolytes, and renal, auditory, and vestibular functions is recommended. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly: dizziness, hearing loss, weakness, or any changes in balance. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Consider birth control options.

Maternal/Child:

Category D: avoid pregnancy. Potential hazard to fetus. ■ Safety for use during breast-feeding not established; use extreme caution. ■ Peak concentrations are generally lower in infants and young children.

Elderly:

Consider less toxic alternatives. Half-life prolonged. Longer intervals between doses may be more important than reduced doses. ■ Advanced age and dehydration may increase risk for toxicity. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ See Precautions.

DRUG/LAB INTERACTIONS

Inactivated in solution with **penicillins** but is synergistic when used in combination with **beta-lactam antibiotics** and **vancomycin.** Do not mix in the same solution. Dose adjustment and appropriate spacing required because of physical **incompatibilities** and interactions. Synergism may be inconsistent; measure aminoglycoside levels. ■ Concurrent and/or sequential use topically or systemically with any other neurotoxic or nephrotoxic agent should be avoided (e.g., amikacin, cisplatin, colistin, neomycin, polymyxin B, tobramycin, vancomycin). ■ May have dangerous additive effects with **anesthetics** (e.g., enflurane), other neuromuscular blocking antibiotics (e.g., kanamycin, streptomycin), **beta-lactam antibiotics** (e.g., cephalosporins), **diuretics** (e.g., furosemide), vancomycin, and many others. ■ **Neuromuscular blocking muscle relaxants** are potentiated by aminoglycosides. ***Apnea can occur.*** ■ Aminoglycosides are also potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); bactericidal action may be impacted.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, or prolonged administration, in dehydrated or elderly patients, and in patients receiving other ototoxic or nephrotoxic drugs.

Anorexia, burning, dizziness, fever, headache, hypertension, hypotension, itching, lethargy, muscle twitching, nausea, numbness, rash, roaring in ears, seizures, tingling sensation, tinnitus, urticaria, vomiting, weight loss.

Major:

Acute organic brain syndrome; blood dyscrasias; CDAD; convulsions; elevated bilirubin, BUN, SCr, AST, and ALT; hearing loss; laryngeal edema; neuromuscular blockade; oliguria; respiratory depression or arrest.

ANTIDOTE

Notify the physician of all side effects. If minor side effects persist or any major symptom appears, notify the physician; may require dose adjustment or discontinuation of gentamicin. Treatment is symptomatic. In overdose or toxic reactions, hemodialysis may be indicated. Rate of gentamicin removal is lower with peritoneal dialysis. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

GLUCAGON

(**GLOO**-kah-gon)
GlucaGen, Glucagon for Injection Baqsimi
Antihypoglycemic
Diagnostic agent
Antidote
pH 2.5 to 3.5

USUAL DOSE

Pretreatment:

Pretesting for patients suspected of having glucagonoma indicated; see Monitor.

Hypoglycemia in adults and pediatric patients weighing more than 20 kg (Glucagon [44 lb]) to 25 kg (GlucaGen [55 lb]):

1 mg. May be given IV, IM, or SC. May be repeated if needed. For severe hypoglycemia or when patient fails to respond to glucagon, IV glucose must be administered. After patient responds to treatment, give fast-acting and long-acting oral carbohydrates to restore liver glycogen and prevent the recurrence of hypoglycemia.

Diagnostic aid: stomach, duodenal bulb, duodenum, and small bowel:

0.2 to 0.5 mg IV or 1 mg IM before procedure begins. When diagnostic procedure is over, administer oral carbohydrates to patients who have been fasting if this is compatible with the diagnostic procedure.

Diagnostic aid: colon:

0.5 to 0.75 mg IV or 1 to 2 mg IM before procedure begins. When diagnostic procedure is over, administer oral carbohydrates to patients who have been fasting if this is compatible with the diagnostic procedure.

Management of cardiac effects of beta-blocker or calcium channel blocker overdose (unlabeled):

3 to 10 mg (0.05 to 0.15 mg/kg) over 3 to 5 minutes. May be followed by an infusion of 3 to 5 mg/hr (0.05 to 0.1 mg/kg/hr). Titrate to patient response.

PEDIATRIC DOSE

Hypoglycemia in infants and children weighing less than 20 kg (Glucagon [44 lb]) to 25 kg (GlucaGen [55 lb]):

20 to 30 mcg/kg or 0.5 mg. See comments under Usual Dose. If the weight is unknown, use 0.5 mg for pediatric patients younger than 6 years of age and 1 mg for those 6 years of age and older.

DOSE ADJUSTMENTS

For uses other than hypoglycemia, lower-end doses may be indicated in the elderly; consider impaired organ function and concurrent disease or other drug therapy.

DILUTION

Dilute 1 unit (1 mg) with 1 mL sterile water for reconstitution (SWFR [if supplied]) or SWFI to achieve a final concentration of approximately 1 mg/mL. Shake vial gently until completely dissolved. Concentrations greater than 1 mg/mL are not recommended. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set if a dextrose solution is infusing.

Reverse effects of beta-blockade:

Reconstitute each 1 unit (1 mg) with 1 mL SWFI. For ***continuous infusion*** this reconstituted solution may be further diluted in D5W to deliver 1 to 5 mg/hr.

Storage:

Use immediately after reconstitution. Discard any unused portion. Before reconstitution, may be stored at CRT for up to 24 months in original package to protect from light. Do not freeze. If solution shows any sign of gel formation or particles after reconstitution, it should be discarded. Do not use after the expiration date on vials.

COMPATIBILITY

May form a precipitate with saline solutions and solutions with a pH of 3 to 9.5. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

Too-rapid rate of injection or doses over 1 mg may increase incidence of side effects

(e.g., nausea and vomiting).
1 unit (1 mg) or fraction thereof over 1 minute. ***Gvoke is given subcutaneously only. Do not give IV.***

ACTIONS

An antihypoglycemic agent and a gastrointestinal motility inhibitor for SC, IM, or IV use. A polypeptide hormone identical to naturally occurring human glucagon produced by recombinant DNA technology. Induces liver glycogen breakdown, releasing glucose from the liver. Glucagon acts only on liver glycogen; hepatic stores of glycogen are necessary for glucagon to produce an antihypoglycemic effect. Blood glucose is raised within 10 minutes. Maximum glucose concentrations are seen about 30 minutes after administration. Duration of antihypoglycemic effect is 60 to 90 minutes. Extrahepatic effect produces relaxation of the smooth muscle of the stomach, duodenum, small bowel, and colon, inhibiting GI motility. Onset of smooth muscle relaxation is less than 1 minute. Duration of smooth muscle relaxation is dose-dependent and ranges from 9 to 25 minutes. Has a half-life of 8 to 18 minutes. Degraded in the liver, kidney, and plasma. Does not cross the placental barrier.

INDICATIONS AND USES

Treatment of severe hypoglycemia (e.g., during insulin therapy in the management of diabetes mellitus). ■ As a diagnostic aid during radiologic examinations to temporarily inhibit movement of the gastrointestinal tract; see Drug/Lab Interactions.

Unlabeled uses:

May be helpful in reversing adverse beta-blockade of beta-adrenergic blocking agents (e.g., propranolol) in overdose situations. ■ If conventional therapy is ineffective, may be helpful in reversing myocardial depression of calcium channel blockers (e.g., diltiazem).

CONTRAINDICATIONS

Glucagon for injection:

Known hypersensitivity to glucagon or its components, patients with known pheochromocytoma, insulinoma, or glucagonoma. **GlucaGen:** Known hypersensitivity to GlucaGen, lactose, or any of its components; patients with pheochromocytoma or insulinoma.

PRECAUTIONS

Easily absorbed IM or SC. ■ If glucagon and glucose do not awaken patient, coma is probably caused by a condition other than hypoglycemia. ■ Use caution in patients with a history suggestive of glucagonoma; secondary hypoglycemia may occur. Treat with adequate carbohydrate intake; see Contraindications and Monitor. ■ May cause the release of catecholamines in patients with pheochromocytoma. Use is contraindicated; see Antidote. ■ Should not be administered to patients suspected of having insulinoma; see Contraindications. Administration may produce an initial increase in blood glucose; however, it may directly or indirectly stimulate exaggerated insulin release from the insulinoma, producing hypoglycemia. Administer IV or oral glucose to a patient who develops symptoms of hypoglycemia. ■ Treatment with glucagon in patients with diabetes mellitus may cause hyperglycemia. ■ Evaluation by a physician is recommended for all patients who experience severe hypoglycemia. ■ Use caution in patients with conditions that result in low levels of releasable glucose (e.g., adrenal insufficiency, chronic hypoglycemia, prolonged fasting, starvation). Insufficient glucose stores will result in inadequate reversal of hypoglycemia. Treatment with dextrose is recommended. ■ Use caution; hypersensitivity reactions have occurred, usually in association with endoscopic examination during which other agents are administered (e.g., contrast media, local anesthetics). ■ When used to inhibit gastrointestinal motility, use caution in patients with known cardiac disease. Glucagon exerts positive inotropic and chronotropic effects and may cause tachycardia and hypertension. ■ Necrolytic migratory erythema (NME), a skin rash commonly associated with glucagon-producing tumors, has been reported following continuous glucagon infusion. ■ Hypotension has been reported for up to 2 hours after use as premedication for upper GI endoscopy procedures. ■ Not all products are packaged with the syringe and diluent necessary for rapid preparation and administration during an emergency outside a health care facility. Ensure that correct product is prescribed and dispensed for outpatient use. ■ See Drug/Lab Interactions.

Monitor:

Prolonged hypoglycemia may result in damage to the central nervous system. Monitor blood glucose levels and mentation. Repeat dose and supplement with IV dextrose (50%) if needed. ■ Monitor BP and HR. In patients with cardiac disease, cardiac monitoring may be indicated. ■ Test patients suspected of having glucagonoma for glucagon levels before treatment, and monitor for changes in blood glucose levels during treatment. ■ Monitor for S/S of NME (e.g., scaly, pruritic erythematous plaques, bullae, and erosions). May affect the face, groin, perineum, and legs or be more widespread. Symptoms have resolved with the discontinuation of the continuous glucagon infusion. Use of corticosteroids not effective. Should NME occur, consider benefits of continuous glucagon infusion versus risk. ■ Emesis on awakening is common. Prevent aspiration by turning patient face down. ■ Depletes glycogen stores, especially in children and adolescents; supplement with fast-acting and long-acting oral carbohydrates on awakening (if able to swallow) to replenish liver glycogen and to prevent recurrence of hypoglycemia. ■ Monitor for S/S of hypersensitivity (e.g., dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ In patients with diabetes mellitus, monitor for hyperglycemia. Administration of insulin may be indicated.

Patient Education:

Eat some form of sugar if hypoglycemia recurs. ■ Report episodes of hypoglycemia and glucagon use at home. Dose adjustment of diabetes medications may be indicated. ■ Hypoglycemia may impair ability to concentrate or react. Do not drive or operate machinery until oral carbohydrates have been consumed and hypoglycemic episode has resolved. ■ Teach patient and family proper storage and preparation of glucagon from kits. Include signs of hypoglycemia and procedures to be followed after administration to an unconscious patient.

Maternal/Child:

Use during pregnancy only if clearly needed. Use caution during breast-feeding. Not absorbed through the GI tract; it would be unlikely to have any effect on the infant. ■ Does not cross the placental barrier. ■ Safety and effectiveness for treatment of severe hypoglycemia in pediatric patients have been demonstrated; however, safety and effectiveness for use in pediatric patients as a diagnostic aid have not been established.

Elderly:

Cautious dosing may be indicated in the elderly; see Dose Adjustments. ■ Differences in response compared with younger adults not identified. ■ If used to inhibit gastrointestinal motility, use caution in elderly patients with known cardiac disease.

DRUG/LAB INTERACTIONS

Beta-blockers may cause a temporary increase in BP and pulse; treatment may be required in patients with coronary artery disease or pheochromocytoma. ■ Concurrent use with **indomethacin** may cause glucagon to lose its ability to raise blood glucose and may even produce hypoglycemia. ■ Coadministration with **anticholinergic** agents (e.g., atropine) is not recommended due to increased GI side effects. ■ May increase the anticoagulant effects of **warfarin**. ■ **Insulin** reacts antagonistically toward glucagon; use caution when glucagon is used as a diagnostic aid in patients with diabetes.

SIDE EFFECTS

Rare in recommended doses: hyperglycemia (in diabetic patients), hypersensitivity reactions (e.g., anaphylaxis, dyspnea, hypotension, rash), hypoglycemia, hypoglycemic coma, hypotension, increased BP, increased HR, nausea, vomiting. Increases in BP and HR may be greater in patients taking beta-blockers.

Post-Marketing:

Necrolytic migratory erythema in patients receiving continuous glucagon infusions.

Overdose:

Nausea and vomiting, increase in BP and HR, inhibition of GI tract motility, hypokalemia.

ANTIDOTE

Nausea and vomiting are tolerable and do occur in hypoglycemia. Antiemetics are indicated when larger doses are given. Increased BP and HR may require treatment in patients with coronary heart disease or pheochromocytoma. Treat sudden increases in BP with phentolamine 5 to 10 mg IV. In overdose situations, glucagon may decrease serum potassium levels; supplemental potassium may be indicated. For any other side effects, discontinue the drug and notify the physician. Treat hypersensitivity reaction as appropriate (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids). Insulin administration may be indicated in acute overdose. Effects of dialysis unknown; unlikely to provide benefit because of the short half-life of glucagon and the nature of the symptoms of overdose. Resuscitate as indicated.

GLUCARPIDASE

(gloo-**KAR**-pi-dase)
Voraxaze
Antidote

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Glucarpidase:

50 units/kg as a single intravenous injection over 5 minutes.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

No dose adjustment is recommended in patients with renal impairment. ■ Has not been studied in patients with hepatic impairment.

DILUTION

Available in a vial containing 1,000 units of lyophilized powder. Reconstitute with 1 mL of NS to provide a solution containing 1,000 units/vial. Roll and tilt vial gently to mix. ***Do not shake.*** Solution should be clear and colorless. Withdraw calculated dose from vial for administration as an IV injection.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Do not use beyond expiration date on vial. Use reconstituted solution immediately or store under refrigeration for up to 4 hours. Discard any unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an injection evenly distributed over 5 minutes. Flush IV line before and after administration.

ACTIONS

A carboxypeptidase enzyme produced by recombinant DNA technology. Hydrolyzes the carboxyl-terminal glutamate residue from folic acid and classic antifolates such as methotrexate. Converts methotrexate to its inactive metabolite, 4-deoxy-4-amino-N10-methylpteroic acid (DAMPA) and glutamate. Glucarpidase provides an alternate nonrenal pathway for methotrexate elimination in patients with renal dysfunction during high-dose methotrexate treatment. The desired end point of therapy is a rapid and sustained clinically important reduction (RSCIR) in methotrexate concentration, which is defined as attaining a plasma methotrexate concentration less than or equal to 1 µmol/L at 15 minutes and sustaining it for up to 8 days after administration of glucarpidase. The likelihood of attaining a RSCIR correlates with the pre-glucarpidase methotrexate concentration. However, even patients with methotrexate concentrations greater than 50 µmol/L were able to achieve greater than 95% reduction in methotrexate concentrations for up to 8 days following glucarpidase administration. Glucarpidase distribution is restricted to the plasma volume. Mean elimination half-life is 5.6 hours.

INDICATIONS AND USES

Reduce toxic plasma methotrexate concentrations (greater than 1 µmol/L) in adult and pediatric patients with delayed methotrexate clearance (plasma methotrexate concentrations greater than 2 standard deviations of the mean methotrexate excretion curve specific for the dose of methotrexate administered) due to impaired renal function.

Limitation of use:

Not recommended for use in patients who exhibit the expected clearance and expected plasma methotrexate concentration. Reducing plasma methotrexate concentration in these patients may result in subtherapeutic exposure to methotrexate.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Serious hypersensitivity reactions, including anaphylaxis, have been reported. ■ Efficacy of a second dose of glucarpidase in patients with markedly elevated pre-glucarpidase methotrexate concentrations was not demonstrated in studies. ■ Continue hydration, alkalinization of the urine, and leucovorin rescue as indicated; see Monitor and methotrexate and leucovorin monographs. ■ A protein substance, it has the potential to produce immunogenicity. Anti-glucarpidase antibodies have been detected in a small number of patients treated with glucarpidase.

Monitor:

Obtain baseline and periodic renal function tests (e.g., SCr and BUN). ■ Watch for early S/S of hypersensitivity or infusion reactions (e.g., chills, dyspnea, fever, flushing, headache, hives, itching, numbness, rash, throat tightness). ■ Monitor methotrexate concentrations. During the first 48 hours after glucarpidase administration, methotrexate concentrations can be reliably measured only by a chromatographic method. During this period, DAMPA (the inactive metabolite of methotrexate) interferes with the measurement of methotrexate concentration using immunoassays. ■ When administering glucarpidase concomitantly with leucovorin, administer leucovorin at least 2 hours before or 2 hours after the glucarpidase dose; see Drug/Lab Interactions. ■ For 48 hours after glucarpidase administration, determine the leucovorin dose based on the patient's pre-glucarpidase methotrexate concentration (i.e., administer the same leucovorin dose given before the glucarpidase dose). Beyond 48 hours, administer leucovorin based on the measured methotrexate concentration. Do not discontinue leucovorin based on the determination of a single methotrexate concentration below the leucovorin rescue threshold. Continue therapy with leucovorin until the methotrexate concentration has been maintained below the leucovorin treatment threshold for a minimum of 3 days; see leucovorin monograph. Monitor for S/S of potential methotrexate toxicity (e.g., abdominal distress, chills, dizziness, fever, leukopenia, malaise, nausea, stomatitis, undue fatigue). ■ Continue IV hydration and urinary alkalinization as indicated.

Patient Education:

Promptly report any S/S of a hypersensitivity reaction or an infusion reaction (e.g., chills, feeling hot, fever, flushing, headache, hives, itching, numbness, rash, throat tightness or breathing problems, tingling). ■ Continued monitoring of methotrexate levels and renal status is imperative.

Maternal/Child:

Safety for use during pregnancy and breast-feeding not established. Administered in combination with methotrexate, which can cause embryo-fetal harm. See methotrexate monograph. ■ Effectiveness in pediatric patients has been established in clinical studies. No overall differences in safety were observed between pediatric patients (age 1 month to 17 years of age) and adult patients.

Elderly:

No overall differences in safety or effectiveness were observed between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Leucovorin is a substrate for glucarpidase. Do not administer leucovorin within 2 hours before or after a dose of glucarpidase. Glucarpidase can decrease leucovorin concentration, which may decrease the effect of leucovorin rescue unless leucovorin is dosed as recommended. ■ Other potential exogenous substrates of glucarpidase include **reduced folates and folate antimetabolites, other folate analogs or folate analog metabolic inhibitors.** ■ During the first 48 hours after glucarpidase administration, methotrexate concentrations can be reliably measured only by a chromatographic method. During this period, DAMPA (the inactive metabolite of methotrexate) interferes with the measurement of methotrexate concentration using immunoassays.

SIDE EFFECTS

The most commonly reported side effects included flushing, headache, hypotension, nausea, paraesthesia, and vomiting. Other reported adverse reactions included blurred vision, diarrhea, hypersensitivity reactions (including anaphylaxis), hypertension, rash, throat irritation or tightness, and tremor.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (airway, oxygen, IV fluids, antihistamines [e.g., diphenhydramine], corticosteroids [e.g., hydrocortisone sodium succinate], epinephrine, pressor amines [e.g., dopamine]) and resuscitate as necessary.

GLYCOPYRROLATE

(**GLYE**-koh-**pye**-roh-layt)
GLYRX-PF
Anticholinergic
Antidote
pH 2 to 3

USUAL DOSE

Dose equivalents in mL are based on the 0.2 mg/mL concentration. Check vial for correct concentration.

Preanesthetic medication:

0.004 mg/kg (0.02 mL/kg) of body weight IM 30 to 60 minutes before anesthesia induction. Usually given at the same time as the preanesthetic narcotic and/or sedative.

Intraoperative medication:

0.1 mg (0.5 mL) IV. Repeat as needed at 2- to 3-minute intervals to counteract drug-induced or vagal reflexes and associated arrhythmias (e.g., bradycardia). Attempt to determine the etiology of arrhythmia and the procedures required to correct parasympathetic imbalance.

Reversal of neuromuscular blockade:

0.2 mg (1 mL) IV for each 1 mg of neostigmine or 5 mg of pyridostigmine; to minimize the bradycardia and excessive secretions caused by these agents used to reverse the neuromuscular blockade of nondepolarizing muscle relaxants. May be administered simultaneously and may be mixed in the same syringe.

Peptic ulcer:

0.1 mg (0.5 mL) at 4-hour intervals 3 to 4 times/day. May be given IV or IM. Adjust frequency of administration based on patient response. Some may require only a single dose. If a more profound effect is required, dose may be increased to 0.2 mg (1 mL).

PEDIATRIC DOSE

See Maternal/Child.

Preanesthetic medication:

Same as Usual Dose. ***Infants 1 month to 2 years of age:*** May require up to 0.009 mg/kg (0.045 mL/kg) of body weight.

Intraoperative medication:

Rarely needed in pediatric patients because of the long duration of action from the preanesthetic dose. If required, administer 0.004 mg/kg (0.02 mL/kg) of body weight IV. Do not exceed 0.1 mg (0.5 mL) in a single dose. Repeat as needed at 2- to 3-minute intervals to counteract drug-induced or vagal traction reflexes and associated arrhythmias (e.g., bradycardia). Attempt to determine the etiology of arrhythmia and the procedures required to correct parasympathetic imbalance.

Reversal of neuromuscular blockade:

Same as Usual Dose.

Peptic ulcer:

Not recommended for treatment of peptic ulcer in pediatric patients; see Maternal/Child.

DOSE ADJUSTMENTS

Caution and lower-end dosing suggested for elderly patients based on potential for decreased organ function and concomitant disease or drug therapy. ■ Elimination prolonged in patients with renal failure. Dose adjustment not provided; see Precautions. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. Administer through Y-tube or three-way stopcock of infusion tubing containing D5 or D10 in water or saline, D5/½NS, NS, or Ringer’s. May be further diluted with D5 or D10 in water or saline.

Filters:

No data available from manufacturer.

Storage:

Store at CRT.

COMPATIBILITY

Manufacturer lists as **incompatible** with lactated Ringer’s and states, “Stability is questionable above a pH of 6. Do not combine in the same syringe with chloramphenicol, dexamethasone, diazepam, dimenhydrinate, methohexital, pentobarbital, secobarbital, sodium bicarbonate, thiopental; will result in a pH above 6 and may result in gas production or precipitation.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

0.2 mg or fraction thereof over 1 to 2 minutes.

ACTIONS

A synthetic anticholinergic agent. It inhibits the action of acetylcholine. It reduces the volume and free acidity of gastric secretions and controls excessive pharyngeal, tracheal, and bronchial secretions. Antagonizes muscarinic symptoms (e.g., bronchorrhea, bronchospasm, bradycardia, and intestinal hypermotility) induced by cholinergic drugs. Onset of action is within 1 minute. Vagal blocking effects last 2 to 3 hours, and antisialagogic (inhibited saliva flow) effects last up to 7 hours. Metabolism has not been studied. Half-life is 0.7 to 0.96 hours. Excreted primarily in urine and to a small extent in bile. Does not effectively cross the blood-brain barrier. Crosses the placental barrier in very small amounts.

INDICATIONS AND USES

Indicated during anesthesia (for all ages) for (1) reduction of salivary, tracheobronchial, and pharyngeal secretions; reduction of volume and acidity of gastric secretions; and blockade of cardiac inhibitory reflexes during induction of anesthesia and intubation; (2) intraoperatively to counteract surgically or drug-induced or vagal reflex–associated arrhythmias; and (3) for protection against peripheral muscarinic effects of cholinergic agents such as neostigmine and pyridostigmine given to reverse the neuromuscular blockade due to nondepolarizing agents. ■ Adjunctive therapy for the treatment of peptic ulcer in adults when rapid anticholinergic effect is desired or when oral medication is not tolerated.

CONTRAINDICATIONS

Known hypersensitivity to glycopyrrolate or any of its inactive ingredients. ■ Peptic ulcer patients with the following concurrent conditions: glaucoma, obstructive uropathy, obstructive disease of the GI tract, paralytic ileus, intestinal atony of the elderly or debilitated, unstable cardiovascular status in acute hemorrhage, severe ulcerative colitis, toxic megacolon complicating ulcerative colitis, and myasthenia gravis. ■ Glycopyrrolate formulations that contain benzyl alcohol are contraindicated in neonates.

PRECAUTIONS

Use IV only when immediate drug effect is essential. ■ Use extreme caution in autonomic neuropathy, asthma, glaucoma, pregnancy, breast-feeding, cardiac arrhythmias, congestive heart failure, coronary artery disease, hepatic or renal disease, hiatal hernia, hypertension, hyperthyroidism, incomplete intestinal obstruction (diarrhea may be an early symptom), ulcerative colitis, and prostatic hypertrophy.

Anticholinergic drugs may aggravate these conditions. ■ Obtain cardiac history before administration of glycopyrrolate; may exacerbate pre-existing tachycardia. ■ Heat prostration can occur with the use of anticholinergic agents in the presence of fever or high environmental temperatures. Pediatric patients and the elderly are at increased risk.

Monitor:

Urinary retention can be avoided if the patient voids just before each dose. ■ Monitor patient for abdominal distension, dyspepsia, early satiety, increased abdominal pain, and vomiting. Discontinue treatment if these symptoms develop or worsen. ■ See Drug/Lab Interactions.

Patient Education:

Inform health care provider of all current medications. ■ Use caution if a task requires alertness; may cause blurred vision, dizziness, or drowsiness. ■ Promptly report constipation, difficulty urinating, dry mouth, flushing, increased light sensitivity, pain and reddening of the eyes (accompanied by dilated pupils), or skin rash. ■ Use caution during exercise or hot weather. Increased heat sensitivity may result in heatstroke. ■ Protect eyes from light after receiving treatment.

Maternal/Child:

Limited data on safety for use in pregnancy. ■ It is not known whether this drug is secreted in breast milk; may suppress lactation; use caution. ■ Safety and effectiveness for use in pediatric patients not established for management of peptic ulcer. ■ Dysrhythmias have been observed in pediatric patients. ■ Pediatric patients may have an increased response to anticholinergics and be at increased risk for side effects (e.g., paradoxical hyperexcitability). Infants and young children, patients with Down syndrome, and pediatric patients with spastic paralysis or brain damage are especially susceptible to this increased response. ■ ***Do not use glycopyrrolate formulations that contain benzyl alcohol in neonates.*** See Contraindications.

Elderly:

Differences in response compared to younger adults not observed. ■ Dosing should be cautious; see Dose Adjustments. ■ May produce excitement, agitation, confusion, or drowsiness in the elderly. ■ May precipitate undiagnosed glaucoma. ■ Risk of urinary retention and constipation increased. ■ May increase memory impairment.

DRUG/LAB INTERACTIONS

Potentiated by other drugs with **anticholinergic activity, antiparkinson drugs, atropine, phenothiazines,** and **tricyclic antidepressants**. Reduced dose of either or both drugs may be indicated. ■ Concomitant administration with **KCl** in a wax matrix may increase the risk and severity of KCl-induced GI lesions (due to slower GI transit time). ■ May decrease antipsychotic effects of **phenothiazines.** Dose adjustment may be required. ■ Risk of ventricular arrhythmias increased when given in presence of **cyclopropane.** Risk is less than with atropine and when given in doses of 0.1 mg or less. ■ Potentiates **atenolol** and **digoxin.**

SIDE EFFECTS

Anaphylaxis, bloated feeling, blurred vision, confusion or excitement, constipation, cycloplegia, decreased sweating, dizziness, drowsiness, dry mouth, dry skin, headache, impotence, increased ocular tension, insomnia, loss of taste, nausea and vomiting, nervousness, palpitation, photophobia, pruritus, suppression of lactation, tachycardia, urinary hesitancy and retention, urticaria, weakness.

Post-Marketing:

Cardiac arrest, cardiac arrhythmias, hypertension, hypotension, malignant hyperthermia, respiratory arrest, seizures.

Overdose:

A curare-like action may occur (i.e., neuromuscular blockade leading to muscular weakness and possible paralysis).

ANTIDOTE

Notify physician of all side effects. May be treated symptomatically or drug may be discontinued. Treat hypotension with IV fluids and/or pressor agents (e.g., dopamine). Initiate artificial respiration if overdose with paralysis of respiratory muscles occurs. Neostigmine, in 0.25-mg increments, may be used to counteract peripheral anticholinergic effects. May repeat every 5 to 10 minutes to a maximum dose of 2.5 mg. Need for repetitive doses of neostigmine should be based on close monitoring of the decrease in HR and the return of bowel sounds. Physostigmine, in increments of 0.5 to 2 mg, may be used to counteract CNS effects. May repeat as needed to a maximum dose of 5 mg. Proportionately smaller doses should be used in pediatric patients. Resuscitate as necessary.

GOLIMUMAB BBW

(goe-**LIM**-ue-mab)
Simponi Aria
Monoclonal antibody
Antirheumatic agent
TNF-blocker
pH 5.5

USUAL DOSE

Pretreatment:

Preliminary patient evaluation and testing required; see Monitor.

Golimumab:

Begin with an initial dose of 2 mg/kg as an infusion over 30 minutes. Repeat at Week 4 and then every 8 weeks thereafter. Given in combination with methotrexate in patients with rheumatoid arthritis (RA). See methotrexate monograph. Patients with RA may continue taking other nonbiologic disease-modifying antirheumatic drugs (DMARDs), corticosteroids, NSAIDs, and/or analgesics. In patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS), golimumab may be given with or without methotrexate or other nonbiologic DMARDs. Corticosteroids, NSAIDs, and/or analgesics may be continued.

The efficacy and safety of switching between IV and SC formulations and routes of administration of golimumab have not been established.

DILUTION

Available as a 50 mg/4 mL concentrated solution for infusion (12.5 mg/mL). Determine the number of vials required using the following calculations:

(Weight in kg × dose/kg) ÷ 50 mg = # of vials required

For a 60-kg patient: [(60 kg) × (2 mg/kg)] ÷ 50 mg/vial = 2.4 vials. After patient is weighed and appropriate dose is calculated, remove sufficient vials from the refrigerator. Aseptic technique imperative. Solution should be colorless to light yellow and may develop a few translucent particles because golimumab is a protein. Do not use if opaque particles, discoloration, or other foreign particles are present. Withdraw the calculated dose (9.6 mL in above example) from the required number of vials. This calculated dose must be further diluted in NS or 0.45% NS to a final total volume of 100 mL. Withdraw and discard a volume of NS or 0.45% NS equal to the calculated volume of golimumab from a 100-mL bottle or bag of solution and slowly add golimumab. Mix gently.

Filters:

Must be administered through an infusion set with an in-line, sterile, non-pyrogenic, low–protein binding filter (pore size 0.22 micrometer or less).

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake. The diluted product may be stored at RT for up to 4 hours. Do not use beyond expiration date. Discard any unused product remaining in vials.

COMPATIBILITY

Manufacturer states, “Do not infuse concomitantly in the same IV line with other agents. No **compatibility** studies have been conducted.”

RATE OF ADMINISTRATION

Use of an infusion set with an in-line, sterile, nonpyrogenic, low–protein binding filter (pore size 0.22 micrometer or less) is required. Use of an infusion pump is helpful. Administer a single dose as an infusion over 30 minutes. Flush the IV line with NS at the end of the infusion to ensure the total dose is received.

ACTIONS

A human monoclonal antibody that binds to both the soluble and transmembrane bioactive forms of human tumor necrosis factor alpha (TNFα). This interaction prevents the binding of TNFα to its receptors, thereby inhibiting the biologic activity of TNFα (a cytokine protein). There has been no evidence of the golimumab antibody binding to other TNF superfamily ligands. Elevated TNFα levels in the blood, synovium, and joints have been implicated in the pathophysiology of rheumatoid arthritis (RA), psoriatic arthritis, and ankylosing spondylitis. Golimumab is thought to be distributed primarily in the circulatory system with limited extravascular distribution. Elimination pathways have not been characterized. Mean terminal half-life is estimated to be 9 to 15 days in healthy subjects and 10 to 18 days in patients with RA. Crosses the placental barrier.

INDICATIONS AND USES

Treatment of adult patients with moderate to severely active rheumatoid arthritis. Used in combination with methotrexate. ■ Treatment of adult patients with active psoriatic arthritis. ■ Treatment of adult patients with active ankylosing spondylitis.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

TNFα mediates inflammation and modulates cellular immune response. Anti-TNF therapies, including golimumab, may affect normal immune responses. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Patients treated with golimumab are at increased risk for developing serious infection that may lead to hospitalization or death. Most patients who developed these infections were taking concomitant immunosuppressant therapy (e.g., methotrexate, corticosteroids) that, in addition to their underlying disease, may predispose them to infection. Treatment with golimumab should not be initiated in patients with an active infection, including clinically important localized infections. ■ Discontinue golimumab if a patient develops a serious infection. Reported infections with TNF-blockers include active tuberculosis, including reactivation of latent tuberculosis (TB); invasive fungal infections (e.g., histoplasmosis, coccidioidomycosis, candidiasis, aspergillosis, blastomycosis, and pneumocystosis); and bacterial, viral, and other infections due to opportunistic pathogens, including *Legionella* and *Listeria*. ■ Patients with TB have frequently presented with disseminated or extrapulmonary disease. ■ Patients with histoplasmosis or other invasive fungal infections may present with disseminated, rather than localized, disease. Antigen and antibody testing for histoplasmosis may be negative. ■ Consider the risks and benefits of golimumab treatment before initiating therapy in patients with chronic or recurrent infection, patients who have been exposed to TB, patients with a history of an opportunistic infection, patients who have resided or traveled in areas of endemic tuberculosis or endemic mycoses (e.g., histoplasmosis, coccidioidomycosis, or blastomycosis), or patients with underlying conditions that may predispose them to infection. ■ Has been associated with the reactivation of hepatitis B virus (HBV) in patients who are chronic hepatitis B carriers (i.e., surface antigen–positive). Fatalities have been reported. ■ Lymphoma and other malignancies, some fatal, have been reported in pediatric, adolescent, and young adult patients treated with TNF-blockers; most of these patients were receiving concomitant immunosuppressants. ■ Rare post-marketing cases of hepatosplenic T-cell lymphoma (HSTCL) have been reported in patients treated with TNF-blocking agents. This rare type of T-cell lymphoma has a very aggressive disease course and is usually fatal. Nearly all cases have occurred in adolescents and young adult males with Crohn's disease or ulcerative colitis who have been treated with azathioprine or 6-mercaptopurine concomitantly with a TNF-blocker at or before diagnosis. ■ Consider risk versus benefit in adult patients with a known malignancy other than a successfully treated nonmelanoma skin cancer (NMSC) or when considering continuing a TNF-blocker in patients who develop a malignancy. ■ In controlled trials, more cases of lymphoma were seen in patients receiving anti-TNF treatment compared with the control group. Patients with RA and other chronic inflammatory diseases, particularly patients with highly active disease and/or chronic exposure to immunosuppressant therapies, may be at higher risk than the general population for developing lymphoma and other malignancies. Melanoma and Merkel cell carcinoma have also been reported in patients treated with TNF-blocking agents. ■ Concurrent use with abatacept or anakinra is not recommended; see Drug/Lab Interactions. ■ Cases of worsening CHF and new-onset CHF have been reported with TNF-blockers, including golimumab. Some incidents have resulted in hospitalization and increased mortality. Use with caution in patients with a history of CHF. Discontinue if new or worsening symptoms of CHF appear. ■ TNF-blockers have been associated with rare cases of new onset or exacerbation of CNS demyelinating disorders, including multiple sclerosis and peripheral demyelinating disorders such as Guillain-Barré syndrome. Use with caution if indicated in these patients. Consider discontinuation of golimumab if these disorders develop. ■ Treatment with TNF-blockers, including golimumab, may result in the formation of antinuclear antibodies. Rarely, treatment with TNF-blockers may result in a lupus-like syndrome. If symptoms suggestive of a lupus-like syndrome develop, discontinue golimumab. ■ Use caution if switching from one biologic product to another (e.g., abatacept, adalimumab, infliximab, golimumab, rituximab); overlapping biologic activity may further increase the risk of infection. ■ Use caution in patients who have or have had significant cytopenias; agranulocytosis, aplastic anemia, leukopenia, neutropenia, thrombocytopenia, and pancytopenia have been reported. ■ May receive vaccinations, except for live virus vaccines; see Drug/Lab Interactions. ■ Hypersensitivity reactions have been reported. ■ Has not been studied in patients with impaired hepatic or renal function.

Monitor:

Before initiating TNF-blocker therapy, including golimumab therapy, patients should be tested for HBV infection. If the test is positive, consultation with a physician with expertise in the treatment of hepatitis B is recommended before beginning treatment. Consider risk versus benefit in patients who are carriers of HBV. ■ In patients who are carriers of HBV and require treatment with TNF-blockers, closely monitor for clinical and laboratory signs of active HBV throughout treatment and for several months after completion of treatment. If HBV reactivation occurs, discontinue golimumab; see

Antidote. ■ Evaluate patients for active and latent TB before and throughout therapy. Initiate treatment for latent TB before therapy with golimumab. ■ Antituberculosis treatment of patients with a reactive TB skin test may reduce the risk of TB reactivation in patients receiving golimumab. Consider antituberculosis therapy before initiation for patients with a history of latent or active TB (if an adequate course of treatment cannot be confirmed) and for patients with a negative TB test who have risk factors for TB infection. Consultation with a physician with expertise in the treatment of TB is recommended. ■ Consider a diagnosis of TB in patients who develop a new infection during treatment. ■ Monitor for S/S of infection during and after treatment with golimumab, including the possible development of TB in patients who tested negative for latent TB before initiating therapy. Discontinue if a serious infection, an opportunistic infection, or sepsis occurs; see Precautions and Antidote. ■ A prompt and complete diagnostic workup appropriate for an immunocompromised patient is indicated for patients who develop a new infection during treatment. Monitor closely and initiate appropriate antimicrobial therapy. Consider empiric antifungal therapy in patients at risk for invasive fungal infections who develop severe systemic illness. ■ Monitor patients for S/S of malignancy. Periodic skin examination is recommended for all patients, particularly those with risk factors for skin cancer. ■ Closely monitor patients with S/S of CHF. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, dyspnea, hives, nausea, and pruritus). Most hypersensitivity reactions occurred during or within 1 hour of the infusion. Some reactions occurred after the first administration of golimumab.

Patient Education:

Read the manufacturer’s medication guide before starting therapy with golimumab and each time the prescription is renewed. ■ Tell health care professionals about heart conditions, previous or current infections, and recent or past exposure to TB or histoplasmosis. ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Lymphoma and other malignancies may occur while receiving golimumab. ■ Promptly report S/S of infection (e.g., burning on urination; chills; cough; diarrhea; fever; stomach pain; warm, red, or painful skin; or sores on body). ■ Promptly report S/S of tuberculosis, invasive fungal infections, and/or hepatitis B reactivation. ■ Promptly report new or worsening conditions such as heart failure (e.g., shortness of breath, swelling feet), demyelinating disorders, autoimmune diseases, liver disease, cytopenias, or psoriasis. ■ Report S/S of hypersensitivity reactions (e.g., itching, rash, swelling in the throat). ■ Report changes of growths on your skin during or after golimumab treatment. ■ Promptly report possible symptoms of lupus (e.g., excessive tiredness, new joint or muscle pain, rash on cheeks, sun sensitivity). ■ Report recently receiving or being scheduled to receive a live virus vaccine or treatment with weakened bacteria (such as BCG for bladder cancer) to your physician. ■ Consider potential benefit and risks of golimumab. ■ See Appendix D, p. 1311.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ There is no information regarding the presence of golimumab in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. ■ Infants exposed to golimumab in utero and infants born to mothers treated with golimumab during pregnancy may be at increased risk for infection for up to 6 months. Administration of live virus vaccines is not recommended for 6 months after the last dose of golimumab that was administered to the mother during pregnancy.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently than younger subjects. ■ Patients over 65 years of age and those with comorbid conditions may be at increased risk for infections.

DRUG/LAB INTERACTIONS

Golimumab should be used with **methotrexate**. Following IV administration, concomitant administration of methotrexate decreased golimumab clearance by reducing the development of anti-golimumab antibodies. ■ Concurrent administration with **other biologic products,** including **anakinra** or **abatacept**, may be associated with an increased risk of serious infections without any increase in benefit. Anakinra is also associated with an increased risk of neutropenia. Concurrent administration of TNF-blocking agents (e.g., golimumab) with other biologics approved to treat RA, including anakinra or abatacept, is not recommended. ■ Concomitant use of **NSAIDs** (e.g., ibuprofen, naproxen), **oral corticosteroids** (e.g., prednisone), or **sulfasalazine** did not influence golimumab SC clearance. ■ **Live virus vaccines** and **therapeutic infectious agents** (e.g., BCG bladder instillation for treatment of cancer) should not be given concurrently with golimumab. Could result in clinical infection, including disseminated infections. In addition, for infants who had in utero exposure to golimumab, it is recommended that live vaccines not be given for at least 6 months after the last golimumab infusion administered to the mother during pregnancy; see Precautions and Maternal/Child. ■ Cytochrome P_{450} enzymes may be suppressed by increased levels of cytokines during chronic inflammation. Golimumab antagonizes cytokine activity, and the formation of the CYP_{450} enzyme may be normalized. When initiating or discontinuing golimumab in patients treated with **CYP450 substrates with a narrow therapeutic index,** monitoring of the effect (e.g., **warfarin**) or drug concentrations (e.g., **cyclosporine** or **theophylline**) is recommended. Dose adjustment may be necessary.

SIDE EFFECTS

The most common side effects are bronchitis, decreased neutrophil count, hypertension, increased liver function tests (e.g., ALT, AST), rash, upper respiratory tract infections, and viral infections. The most serious were malignancies (e.g., lymphoma, skin cancer) and serious infections (e.g., abscess, cellulitis, invasive fungal infections, opportunistic infections, pneumonia, sepsis, and tuberculosis). Other less common side effects include bullous skin reactions, constipation, dizziness, fever, infusion reactions (e.g., rash), leukopenia, lower respiratory tract infection (pneumonia), paresthesia, pyelonephritis, sinusitis, superficial fungal infections.

Post-Marketing:

Bullous skin reactions, infusion-related reactions, interstitial lung disease, lichenoid reactions, melanoma, Merkel cell carcinoma, sarcoidosis, serious systemic hypersensitivity reactions (including anaphylactic reactions), skin exfoliation. Rare cases of hepatosplenic T-cell lymphoma have been reported with TNF-blockers.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue golimumab if patient experiences a serious infection, a serious hypersensitivity reaction, new or worsening S/S of heart failure, new or worsening S/S of CNS demyelinating disorders (multiple sclerosis [MS]), peripheral demyelinating disorders (including Guillain-Barré syndrome), or a lupus-like syndrome. Treat a hypersensitivity reaction with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Discontinue golimumab in patients who develop HBV reactivation, and initiate antiviral therapy with appropriate supportive treatment. Safety of resuming therapy after HBV is controlled is not known; use caution if resumption of therapy is considered and monitor closely.

GOLODIRSEN INJECTION

(**GOE**-loe-**DIR**-sen in-**JEK**-shun)
Vyondys 53
Antisense oligonucleotide
pH 7.5

USUAL DOSE

Pretreatment:

Pretesting and baseline studies required; see Monitor.

Premedication:

Application of a topical anesthetic cream to the infusion site before administration of golodirsen may be considered.

Golodirsen:

30 mg/kg once weekly as IV infusion over 35 to 60 minutes.

DOSE ADJUSTMENTS

Renal clearance of golodirsen is reduced in non-DMD adults with renal impairment. However, because of the effect of reduced skeletal muscle mass on creatinine measurements in DMD patients, no specific dose adjustment can be recommended for DMD patients with renal impairment based on estimated glomerular filtration rate.

DILUTION

Available as single-dose vials containing 100 mg/2 mL (50 mg/mL) as a preservative-free concentrated solution that requires dilution before administration. Calculate the total dose to be administered based on the patient's weight and the recommended dose of 30 mg/kg. Determine the volume needed and the correct number of vials to supply the full calculated dose. For example, in a 70-kg patient:

1. 30 mg/kg × 70 kg = 2,100 mg
2. 2,100 mg ÷ 50 mg/mL = 42 mL
3. 2,100 mg ÷100 mg/vial = 21 100-mg vials, so 21 100-mg vials would be needed.

Allow the vials to warm to RT. Mix the contents of each vial by gently inverting 2 or 3 times. ***Do not shake.*** Solution is a clear to slightly opalescent, colorless liquid. Do not use if discolored or particulate matter is present. Using a syringe fitted with a 21-gauge or smaller noncoring needle, withdraw the calculated volume of golodirsen from the appropriate number of vials. Further dilute with NS to make a total volume of 100 to 150 mL. Gently invert 2 or 3 times to mix. ***Do not shake.***

Filters:

No specific recommendations stated.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. ***Do not freeze.*** Complete infusion of the diluted solution within 4 hours of dilution, or it may be refrigerated for up to 24 hours. ***Do not freeze.*** Discard unused golodirsen.

COMPATIBILITY

Manufacturer states, "Do not mix other medications with golodirsen or infuse other medications concomitantly via the same IV access line."

RATE OF ADMINISTRATION

A single dose as an IV infusion equally distributed over 35 to 60 minutes. Flush the IV line with NS before and after infusion. If a hypersensitivity reaction occurs, slow or interrupt the rate of infusion based on severity.

ACTIONS

An antisense oligonucleotide. It is designed to bind to exon 53 of dystrophin pre-mRNA, resulting in exclusion of this exon during mRNA processing in patients with genetic mutations that are amenable to exon 53 skipping. Exon 53 skipping is intended to allow for production of an internally truncated dystrophin protein in patients with genetic mutations that are amenable to exon 53 skipping. Golodirsen is metabolically stable. No metabolites were detected in plasma or urine. Elimination half-life is 3.4 hours. Mostly excreted unchanged in urine.

INDICATIONS AND USES

Treatment of Duchenne muscular dystrophy (DMD) in patients who have a confirmed mutation of the DMD gene that is attenable to exon 53 skipping. Approved under accelerated approval based on an increase in dystrophin production in skeletal muscle observed in treated patients.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Usually administered in a setting with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including dermatitis, fever, pruritus, rash, skin exfoliation, and urticaria, have occurred. Some required treatment. ■ Renal toxicity was observed in animals who received golodirsen. Although not observed in the clinical studies, renal toxicity, including potentially fatal glomerulonephritis, has been observed after administration of some antisense oligonucleotides. ■ Use with caution in patients with renal impairment; see Dose Adjustments. ■ Has not been studied in patients with hepatic impairment.

Monitor:

Confirm presence of the DMD gene mutation that is amenable to exon 53 skipping. ■ Measurement of glomerular filtration rate (GFR) by 24-hour urine collection before initiation of therapy is recommended. ■ Monitor for renal toxicity during treatment. Because of the effect of reduced skeletal muscle mass on creatinine measurements, creatinine may not be a reliable measure of renal function in DMD patients. Monthly monitoring for proteinuria by dipstick urinalysis and monitoring of serum cystatin C every 3 months is recommended. If a dipstick proteinuria of 2+ or greater or elevated serum cystatin C is confirmed, a 24-hour urine collection to quantify proteinuria and assess GFR should be performed. ■ Monitor patients with known renal function impairment closely during treatment. ■ Monitor for S/S of a hypersensitivity-infusion reaction.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., dermatitis, fever, pruritus, rash, skin exfoliation, and urticaria). ■ Monitoring for renal toxicity indicated.

Maternal/Child:

No human or animal data are available to assess the use of golodirsen during pregnancy. ■ No human or animal data available to assess the effect of golodirsen on milk production, the presence of golodirsen in milk, or the effects on the breast-fed infant. Consider risk versus benefit. ■ Is indicated in patients with DMD who have a confirmed mutation of the DMD gene that is amenable to exon 53 skipping, including pediatric patients.

Elderly:

Largely a disease of children and young adults; there is no geriatric experience with golodirsen.

DRUG/LAB INTERACTIONS

Based on in vitro data, golodirsen has a low potential for drug-drug interactions in humans.

SIDE EFFECTS

Abdominal pain, cough, falls, fever, headache, nasopharyngitis, nausea, and vomiting are most common. Administration site pain, back pain, catheter site–related reactions, constipation, contusions, diarrhea, dizziness, ear infection, fracture, influenza, ligament sprain, oropharyngeal pain, pain, rhinitis, seasonal allergy, skin abrasion, and tachycardia have also been reported. Hypersensitivity reactions have been reported.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be tolerated or treated symptomatically. If a hypersensitivity reaction occurs, institute appropriate medical treatment (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids), and consider slowing the infusion or interrupting golodirsen therapy. Resuscitate as necessary.

GRANISETRON HYDROCHLORIDE

(gran-**ISS**-eh-tron hy-droh-**KLOR**-eyed)
Antiemetic (5-HT$_3$ receptor antagonist)
pH 4 to 6

USUAL DOSE

Chemotherapy-induced nausea and vomiting (prophylaxis):

A single dose of 10 mcg/kg of body weight as an injection or as an infusion. Begin within 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, carboplatin) and only on the day(s) chemotherapy is given. Clinical trials used doses up to 40 mcg/kg with effects similar to the recommended 10-mcg/kg dose. Some studies question the effectiveness of a 10-mcg/kg dose. Repeat doses are frequently required to prevent nausea with chemotherapy. Oral granisetron is available.

Prevention and treatment of postoperative nausea and vomiting:

1 mg before induction of anesthesia, immediately before reversal of anesthesia, or postoperatively.

PEDIATRIC DOSE

Chemotherapy-induced nausea and vomiting (prophylaxis) in pediatric patients 2 to 16 years of age:

Identical to adult dose. See Maternal/Child.

DOSE ADJUSTMENTS

No dose adjustment required for the elderly or in renal failure or impaired hepatic function.

DILUTION

Read label carefully. Available in two concentrations (0.1 mg/mL and 1 mg/mL). The 0.1-mg/mL vial contains no preservatives. The 1-mg/mL single-dose and multidose vials contain benzyl alcohol. Sterile technique imperative when withdrawing a single dose from the multidose vial; see Storage.

A single dose may be given undiluted by IV injection or further diluted to a total volume of 20 to 50 mL with NS or D5W and given as an infusion.

Storage:

Store vials at CRT or below. Do not freeze; protect from light. Should be administered after dilution (preservative free) but is stable up to 24 hours at room temperature. Discard multidose vial within 30 days of initial penetration.

COMPATIBILITY

Manufacturer recommends not mixing in solution with other drugs as a general precaution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 30 seconds.

Intermittent infusion:

A single dose equally distributed over 5 minutes.

ACTIONS

An antinauseant and antiemetic agent. A selective antagonist of specific serotonin (5-HT_3) receptors. Chemotherapeutic agents such as cisplatin increase the release of serotonin from specific cells in the GI tract, causing emesis. By antagonizing these receptors, chemotherapy-induced nausea and vomiting are prevented. Has little effect on BP, HR, ECG, plasma prolactin, or aldosterone concentrations. Moderately bound to protein (65%). Distributes freely between plasma and RBCs. Metabolized in the liver by hepatic cytochrome P_{450} enzymes. Mean half-life is approximately 9 hours. Excreted in urine and feces.

INDICATIONS AND USES

Prevention of nausea and vomiting associated with initial and repeat courses of emetogenic cancer therapy, including high-dose cisplatin. Has been shown to be effective with most emetogenic antineoplastic agents. ■ Prevention and treatment of postoperative nausea and vomiting in adults.

Unlabeled uses:

Prevention of nausea and vomiting associated with total body radiation or fractional abdominal radiation.

CONTRAINDICATIONS

Known hypersensitivity to granisetron.

PRECAUTIONS

Stool softeners or laxatives may be required to prevent constipation. ■ See Drug/Lab Interactions. ■ Hypersensitivity reactions have been reported. Use caution in patients who have exhibited hypersensitivity to other selective 5-HT_3 receptor antagonists. Cross-sensitivity has been reported between dolasetron and other agents in this class (e.g., granisetron, ondansetron). ■ The use in patients following abdominal surgery or in patients with chemotherapy-induced nausea and vomiting may mask a progressive ileus and/or gastric distension. ■ Does not stimulate GI motility and should not be used instead of NG suction. ■ QT prolongation has been reported. Use with caution in patients with pre-existing arrhythmias, cardiac conduction disorders, or electrolyte abnormalities or in patients who are taking other medications that can prolong the QT interval; see Drug/Lab Interactions. ■ Serotonin syndrome has been reported with 5-HT_3 receptor antagonists. Most reports were associated with concomitant use of serotonergic drugs (e.g., selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, monoamine oxidase inhibitors, mirtazapine, fentanyl, lithium, tramadol, and intravenous methylene blue). Some cases were fatal. ■ Not recommended if nausea and vomiting are not expected postoperatively unless nausea and vomiting must be avoided during the postoperative period.

Monitor:

Ambulate slowly to avoid orthostatic hypotension. ■ Monitor for S/S of hypersensitivity (e.g., anaphylaxis, hypotension, shortness of breath, urticaria). ■ Monitor ECG in patients at risk for prolongation of the PR and QRS interval; see Precautions. ■ Monitor for serotonin syndrome, especially when dolasetron is used concurrently with other serotonergic drugs. Symptoms associated with serotonin syndrome may include the following combination of S/S: mental status changes (e.g., agitation, coma, delirium, hallucinations), autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile blood pressure, tachycardia), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), seizures, with or without GI symptoms (e.g., diarrhea, nausea, vomiting).

Patient Education:

Request assistance for ambulation. ■ Report promptly if nausea persists for more than

10 minutes. ■ Maintain adequate hydration. ■ Stool softeners may be required to avoid constipation. ■ Promptly report S/S of serotonin syndrome (e.g., altered mental status, autonomic instability, and neuromuscular symptoms); see Precautions.

Maternal/Child:

Category B: no evidence of impaired fertility or harm to fetus. Benzyl alcohol may cross the placenta; see Dilution. Use during pregnancy only if benefits justify risks. ■ Use caution if required during breast-feeding. ■ Safety and effectiveness for use in the treatment of chemotherapy-induced nausea and vomiting in pediatric patients under 2 years of age have not been established. ■ Not recommended for prevention and treatment of postoperative nausea and vomiting in pediatric patients due to a lack of efficacy and QT prolongation observed in a clinical trial.

Elderly:

Response similar to other age-groups. ■ Clearance lower and half-life prolonged but has no clinical significance.

DRUG/LAB INTERACTIONS

Metabolism may be inhibited by **ketoconazole**. Clinical significance unknown. ■ Does not induce or inhibit the cytochrome P_{450} drug metabolizing system, but definitive interaction studies have not been done. Its clearance and half-life may be affected by **inducers of these enzymes** such as anticonvulsants or rifampin or by **inhibitors of these enzymes** (e.g., cimetidine, calcium channel blockers, antiviral agents [e.g., indinavir, ritonavir, saquinavir]). ■ Has been safely administered with **benzodiazepines, neuroleptics**, and **antiulcer drugs** commonly prescribed with antiemetic treatment. ■ Does not appear to interact with emetogenic cancer chemotherapies. ■ Concurrent use with **drugs known to prolong the QT interval** (e.g., amiodarone, antihistamines, azole antifungals, disopyramide, fluoroquinolones, ibutilide, mexiletine, phenothiazines, procainamide, quinidine, and tricyclic antidepressants) may result in clinical consequences. ■ Serotonin syndrome (including altered mental status, autonomic instability, and neuromuscular symptoms) has been reported following the concomitant use of 5-HT_3 receptor antagonists and other serotonergic drugs, including selective serotonin reuptake inhibitors (SSRIs) and serotonin and norepinephrine reuptake inhibitors (SNRIs); see Precautions.

SIDE EFFECTS

Asthenia (5%), constipation (3%), diarrhea (4%), headache (14%), somnolence (4%), and weakness (5%) occur most frequently. Hypersensitivity reactions, including anaphylaxis (rare), have occurred. Transient elevation of AST or ALT may occur. Other side effects include abdominal pain, anemia, anxiety, bradycardia, coughing, dizziness, dyspepsia, fever, hypertension, hypotension, infection, insomnia, leukocytosis, oliguria, pain. Other side effects have occurred in fewer than 2% of patients but could not be clearly associated with granisetron.

Post-Marketing:

QT prolongation. Serotonin syndrome has been reported as a 5-HT_3 class reaction.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed as indicated. There is no specific antidote. If symptoms of serotonin syndrome occur, discontinue granisetron and initiate supportive care. Treat anaphylaxis and resuscitate as necessary.

Generic drugs: H

HEMIN
HEPARIN SODIUM
HEPATITIS B IMMUNE GLOBULIN INTRAVENOUS (HUMAN)
HETASTARCH
HYDRALAZINE HYDROCHLORIDE
HYDROCORTISONE SODIUM SUCCINATE
HYDROMORPHONE HYDROCHLORIDE
HYDROXOCOBALAMIN
6% HYDROXYETHYL STARCH 130/0.4 IN 0.9% SODIUM CHLORIDE INJECTION

H

HEMIN BBW

(**HEE**-men)
Panhematin
Porphyrin inhibitor

USUAL DOSE

A single dose of 1 to 4 mg/kg of body weight/24 hr of hematin for 3 to 14 days. This dose could be repeated in 12 hours for severe cases. Never exceed a total dose of 6 mg/kg/24 hr. Length of treatment dependent on severity of symptoms and clinical response. See Precautions.

DILUTION

Each vial containing 313 mg of hemin must be diluted with 43 mL of SWFI (provides 301 mg of hematin). Shake well for 2 to 3 minutes to ensure dissolution. Each 1 mL contains 7 mg hematin. Each 0.14 mL contains 1 mg hematin. May be given directly from vial as an infusion or through Y-tube or three-way stopcock of infusion set.

Filters:

Use of a 0.45-micron or smaller in-line filter recommended.

Storage:

Store in refrigerator at 2° to 8° C (36° to 46° F). Contains no preservative, decomposes rapidly; discard unused solution.

COMPATIBILITY

Undergoes rapid chemical decomposition in solution. Manufacturer states, “No drug or chemical agent should be added unless its effect on the chemical and physical stability has been determined.” Specific information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose evenly distributed over 10 to 15 minutes.

ACTIONS

An iron-containing metalloporphyrin enzyme inhibitor extracted from RBCs. Inhibits rate of porphyria/heme biosynthesis in the liver and bone marrow by an unknown mechanism. Induces remission of symptoms only; not curative. Some excretion occurs in urine and feces.

INDICATIONS AND USES

To control symptoms of recurrent attacks of acute intermittent porphyria in selected patients (often related to the menstrual cycle in susceptible women).

CONTRAINDICATIONS

Hypersensitivity to hemin; porphyria cutanea tarda.

PRECAUTIONS

Confirm diagnosis of acute porphyria before use (positive Watson-Schwartz or Hoechst test). Administered by or under the supervision of a physician experienced in the treatment of porphyrias and in facilities equipped to monitor the patient and respond to any medical emergency. ■ Alternate therapy of 400 Gm glucose/24 hr for 1 to 2 days should be tried before use of hemin is initiated. ■ Give as early as possible with onset of attack to achieve the most benefit. ■ Must be given before irreversible neuronal damage of porphyria has begun. ■ See Drug/Lab Interactions.

Monitor:

Use of a large arm vein or central venous catheter recommended to avoid phlebitis. ■ Effectiveness monitored by decrease in urine concentration of S-aminolevulinic acid (ALA), uroporphyrinogen (UPG), or porphobilinogen (PBG).

Maternal/Child:

Category C: safety for use during pregnancy, breast-feeding, and in pediatric patients not established.

DRUG/LAB INTERACTIONS

Action inhibited by **estrogens, barbiturates, and steroid metabolites.** Avoid concurrent use. ■ Has mild anticoagulant effects. Avoid concurrent use with **anticoagulants** (e.g., heparin, warfarin).

SIDE EFFECTS

Almost nonexistent with usual dosage and appropriate technique; fever, phlebitis. Reversible renal shutdown has been reported with excessive doses.

ANTIDOTE

Discontinue temporarily if known or questionable side effect appears, and notify physician. Renal shutdown of overdose has responded to ethacrynic acid (Edecrin) and mannitol. Treat anaphylaxis (antihistamines, epinephrine, corticosteroids) and resuscitate as necessary.

HEPARIN SODIUM

(**HEP**-ah-rin **SO**-dee-um)
Anticoagulant
pH 5 to 7.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.
Confirm choice of the correct heparin product; see Precautions.

Intermittent injection for therapeutic anticoagulation (based on a 68-kg [150-lb] patient):

10,000 units initially. Dosage is repeated every 4 to 6 hours and adjusted according to coagulation test results. Usually 5,000 to 10,000 units. Initial and repeat doses may be given undiluted or may be diluted in 50 to 100 mL of NS.

IV infusion for therapeutic anticoagulation (based on a 68-kg [150-lb] patient):

An initial bolus dose of 5,000 units is required. 20,000 to 40,000 units/24 hr in NS or other **compatible** infusion solution. Adjust dose according to coagulation test results.

Treatment of venous thromboembolism (VTE):

American College of Chest Physicians recommends an initial bolus of 80 units/kg (alternately 5,000 units) followed by an initial continuous infusion of 18 units/kg/hr (alternately 1,000 units/hr) for VTE.

Adjuvant therapy in treatment of AMI:

AHA guidelines recommend an initial bolus dose of 60 units/kg of body weight (maximum dose 4,000 units). Follow with an infusion of 12 units/kg/hr. The initial maximum recommended infusion rate is 1,000 units/hr. Adjust to maintain aPTT at 1.5 to 2 times control. Other protocols are in use.

Adjuvant therapy during treatment with thrombolytic agents (e.g., alteplase, reteplase, streptokinase) and glycoprotein GPIIb/IIIa receptor antagonists (e.g., abciximab, eptifibatide, tirofiban):

See individual monographs for suggested doses.

Open heart surgery:

150 to 400 units/kg of body weight during surgical procedure, depending on duration of procedure. Frequently, a dose of 300 units/kg is administered for procedures estimated to last less than 60 minutes. 400 units/kg may be given for procedures estimated to last longer than 60 minutes.

Disseminated intravascular coagulation:

Use and dose of heparin is based on severity of DIC and underlying cause and extent of thrombosis. Several dosing regimens have been used; see literature.

Maintain patency of indwelling venipuncture devices (e.g., heparin-lock, catheter, or implanted port) intended for intermittent use:

Consult device manufacturer's instructions for specific requirements regarding its use. 10 unit/mL concentration is commonly used for younger infants (less than 10 kg). Higher concentration of 100 units/1 mL is used in older infants, pediatric patients, and adults. Volume of heparin flush solution should be similar to volume of catheter. May be used after initial placement of the device in the vein, after each medication injection, after withdrawal of blood for laboratory tests, or every 8 to 24 hours to maintain patency of device. Confirm patency by aspirating before each injection. Flush with SWFI or NS before and after any medication **incompatible** with heparin. Re-instill heparin after second flush. If additional medications are not needed, each single dose of heparin will prevent clotting within the lumen of indwelling venipuncture devices for up to 24 hours.

Blood transfusion:

400 to 600 units/100 mL whole blood.

Converting to an oral anticoagulant:

When converting from heparin to **warfarin** (Coumadin), begin warfarin on the first or second day of heparin therapy at the usual initial dose and determine PT/INR at the usual intervals. To ensure continuous anticoagulation, continue full heparin therapy for several days until the PT/INR has reached a therapeutic range (INR of 2 or greater) for at least 24 hours. Once target PT/INR has been achieved and maintained, heparin therapy can be discontinued without tapering. When initiating oral therapy with an oral anticoagulant, stop the heparin infusion immediately after the first dose of the oral anticoagulant. For intermittent IV administration of heparin, start the oral anticoagulant 0 to 2 hours before the time that the next dose of intermittent heparin was to have been administered.

PEDIATRIC DOSE

Read label carefully. Comes in many strengths. Confirm use of the correct strength. Fatal hemorrhages have occurred in pediatric patients, including neonates, as a result of medication errors in which heparin sodium injection vials have been confused with heparin-lock flush vials.

Do not use products containing benzyl alcohol in neonates or infants. Preservative-free solution is required for neonates and infants. See Maternal/Child.

Full-dose continuous IV infusion:

A ***loading dose*** of 75 to 100 units/kg administered over 10 minutes and a ***maintenance dose*** (to maintain an aPTT of approximately 60 to 85 seconds or a range corresponding to an anti-factor Xa level of 0.35 to 0.7) based on age as follows:

Infants under 2 months:

(Have the highest requirements) Average 28 units/kg/hr.

Infants 2 months to 1 year of age:

25 to 30 units/kg/hr.

Over 1 year of age:

18 to 20 units/kg/hr.

Older pediatric patients:

May require less heparin, similar to the weight-adjusted dose in adults (18 units/kg/hr).

Disseminated intravascular coagulation:

Use and dose of heparin are based on severity of DIC and underlying cause and extent of thrombosis. Several dosing regimens have been used; see literature.

Patency of indwelling venipuncture devices:

See Maternal/Child. Safety and effectiveness of the 100-USP units/mL heparin-lock flush solution for pediatric patients not established. Patency for peripheral devices (e.g., single- and double-lumen central catheters) is usually accomplished with 10 units/mL heparin solution in younger infants (e.g., less than 10 kg) and with 100 units/mL for older infants, children, and adults. Avoid approaching therapeutic unit/kg dose. Follow catheter manufacturer's guidelines. See all comments under similar section in Usual Dose.

DOSE ADJUSTMENTS

Reduction of initial dose indicated in patients 60 years of age and older (especially women). Adjust dose based on coagulation tests; see Monitor.

DILUTION

May be given undiluted or diluted in any given amount of NS, dextrose, or Ringer's solution for infusion and given by IV injection, as an intermittent IV, or continuous IV infusion. When added to an infusion solution for continuous IV administration, invert container a minimum of 6 times to ensure adequate mixing and to prevent pooling of heparin in the solution. Available in several strengths for administration or dilution as well as in several premixed concentrations and volumes. Unit-dose heparin flush syringes are not for multiple use; discard unused portions.

Intermittent injection or infusion:

Usually given undiluted or may be diluted in 50 to 100 mL of NS or D5W.

Continuous infusion:

Available in several manufacturer-supplied concentrations. If prepared, may be diluted in 250 to 1,000 mL of **compatible** solution to provide a 24-hour dose. See chart on inside back cover.

Blood transfusion:

Add 7,500 units heparin to 100 mL NS. Add 6 to 8 mL of this sterile solution to each 100 mL of whole blood.

Filters:

No significant reduction in potency when 10,000 units diluted in D5W or NS was filtered through a 0.22-micron cellulose ester membrane filter.

Storage:

Store at CRT. Do not freeze. Do not use if solution is discolored or contains a precipitate. Storage of prepared (diluted) heparin infusion solutions should not exceed 4 hours at RT or 24 hours refrigerated.

COMPATIBILITY

Several sources recommend not mixing or administering through the same IV line with other drugs until **compatibility** confirmed. To avoid precipitation with heparin, they also caution to flush with SWFI or NS before and after any acidic or **incompatible** medication or solution. Manufacturer lists as **incompatible** in solution with alteplase, amikacin, atracurium, ciprofloxacin, cytarabine, daunorubicin, droperidol, erythromycin, gentamicin, idarubicin, kanamycin, mitoxantrone, polymyxin B, promethazine, streptomycin, and tobramycin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single injection (5,000 units or fraction thereof) may be given over 1 minute. A continuous IV infusion may be given over 4 to 24 hours, depending on specific dosage of heparin required, amount of heparin added, and amount of infusion fluid used as a diluent. Continuous IV infusion is the preferred method of administration. Use an infusion pump for accuracy.

ACTIONS

An anticoagulant with immediate and predictable effects on the blood. Inhibits reactions that lead to clotting of blood and the formation of fibrin clots. Heparin combines with other factors in the blood to inhibit the conversion of prothrombin to thrombin and fibrinogen to fibrin. Adhesiveness of platelets is reduced. Well-established clots are not dissolved, but growth is prevented and newer clots may be dissolved. Duration of action is short, about 4 to 6 hours. Average plasma half-life is 30 to 120 minutes. The half-life of the anticoagulant effect of heparin is approximately 1.5 hours and does not increase with dose. Metabolic fate not fully determined. May be partially metabolized in the liver and the reticuloendothelial system. Small amount excreted as unchanged drug in the urine.

INDICATIONS AND USES

Prevention and/or treatment of all types of thromboses and emboli, including deep vein thrombosis (DVT), pulmonary emboli (PE), thromboembolic complications associated with atrial fibrillation (AF), and peripheral arterial embolism. ■ Treatment of disseminated intravascular coagulation (DIC). ■ Prevention of clotting in arterial and cardiac surgery and during blood transfusion, extracorporeal circulation, and dialysis procedures. ■ Maintain patency of an indwelling venipuncture device designed for intermittent injection or infusion therapy or blood sampling (e.g., heparin-lock, catheter, or implanted port).

Unlabeled uses:

Adjunct in treatment of coronary occlusion with acute myocardial infarction (MI). ■ Adjunct to use of glycoprotein GP IIb/IIIa receptor antagonists in percutaneous coronary intervention (PCI). ■ ST-elevation MI, as an adjunct to thrombolysis.

CONTRAINDICATIONS

History of heparin-induced thrombocytopenia (HIT) and heparin-induced thrombocytopenia and thrombosis (HITT). ■ Severe thrombocytopenia. ■ Patients receiving full-dose heparin unless blood coagulation tests can be performed at appropriate intervals. ■ Hypersensitivity to heparin (or any of its components [may contain sulfites]) or pork products. ■ Uncontrolled bleeding except in DIC. ■ Do not administer heparin preparations preserved with benzyl alcohol to neonates, infants, pregnant women, or breast-feeding mothers.

PRECAUTIONS

Read label carefully. Comes in many strengths. Confirm use of the correct strength. Fatal hemorrhages have occurred in pediatric patients, including neonates, as a result of medication errors in which heparin sodium injection vials have been confused with heparin-lock flush vials. ■ For IV or SC use only; avoid IM administration (may cause hematomas). ■ Derived from animal protein (pork). ■ Avoid using heparin in the presence of major bleeding, except when the benefits of heparin therapy outweigh the potential risks. ■ Use extreme caution in any disease state or clinical condition in which risk of hemorrhage may be increased, such as subacute bacterial endocarditis; severe hypertension; during or following spinal tap, spinal anesthesia, or major surgery (especially major surgery involving the brain, spinal cord, or eye); hemophilia; thrombocytopenia; gastrointestinal ulcerative lesions; vascular purpuras; patients with hereditary antithrombin III deficiency receiving concurrent antithrombin III therapy (see Drug/Lab Interactions); continuous tube drainage of the stomach or small intestine; menstruation; or severe liver disease with impaired hemostasis. ■ Resistance to heparin increased in cancer, fever, infections with thrombosing tendencies, MI, patients with antithrombin III deficiency, postsurgical patients, thrombophlebitis, and thrombosis. ■ May cause thrombocytopenia; monitor closely. ■ May develop heparin-induced thrombocytopenia (HIT), an antibody-mediated reaction resulting from irreversible aggregation of platelets. HIT may progress to heparin-induced thrombocytopenia and thrombosis (HITT), which involves the development of venous and arterial thromboses. HIT and HITT may occur during heparin treatment or may be delayed for up to several weeks after heparin treatment is discontinued; see Monitor. ■ See Elderly for additional precautions. ■ Repeated flushing of an indwelling venipuncture device with heparin may result in a systemic anticoagulant effect. ■ Heparin-lock flush solution is intended for maintenance of patency of intravenous injection devices only and is not to be used for anticoagulant therapy. ■ See Maternal/Child.

Monitor:

Obtain baseline coagulation studies (e.g., whole blood clotting time [WBCT], activated coagulation time [ACT], activated partial thromboplastin time [aPTT], and INR) and a baseline CBC with platelets. ■ Dose is considered adequate when the aPTT is 1.5 to 2 times normal or when the WBCT is elevated approximately 2.5 to 3 times the control value. Confirm desired control level with physician. ■ During the early stages of treatment, coagulation tests are often done before each intermittent injection or every 4 hours with a continuous infusion. Once the patient is adequately anticoagulated and stable, monitoring may be decreased to daily. Reinstitute more frequent monitoring with any dose adjustment, change in patient condition, or change in therapy that might affect anticoagulation status. Notify the physician if aPTT, ACT, or WBCT is above therapeutic level. ■ Monitor platelet count periodically. Discontinue heparin if it falls below 100,000 or a thrombosis forms. May develop HIT or HITT. Immune-mediated HIT is diagnosed based on clinical findings supplemented by laboratory tests confirming the presence of antibodies to heparin or platelet activation induced by heparin. Thrombotic events may be the initial presentation for HITT and may include DVT, cerebral vein thrombosis, limb ischemia, mesenteric thrombosis, thrombus formation on a prosthetic cardiac valve, or renal artery thrombosis; skin necrosis; gangrene of the extremities that may lead to amputation; MI; pulmonary embolism; stroke; or death. HIT and HITT may occur during heparin therapy or may be delayed. Evaluate patients for HIT and HITT if they present with thrombocytopenia or thrombosis after heparin is discontinued. Can occur up to several weeks after heparin is discontinued. ■ Also monitor hematocrit and occult blood in stool. ■ Hemorrhage can occur at any site and is the primary complication. Monitor closely. Consider the possibility of a hemorrhagic event with an unexplained fall in hematocrit, a fall in BP, or any other unexplained symptom. GI or urinary tract bleeding may indicate an underlying lesion. Certain hemorrhagic complications may be difficult to detect and can be very serious (e.g., adrenal [with resultant adrenal insufficiency], ovarian [corpus luteum], and retroperitoneal hemorrhage). ■ Use extensive precautionary methods to prevent bleeding if patient requires IM injection, arterial puncture, or venipuncture. ■ Monitor coagulation tests closely in patients who develop resistance to heparin. Adjustment of heparin doses based on anti-Factor Xa levels may be warranted; see Precautions. ■ Monitor for S/S of a hypersensitivity reaction in patients with allergies; derived from animal tissue, and some products may contain a sulfite preservative.

Patency of indwelling venipuncture devices:

Obtain a baseline aPTT prior to insertion of an indwelling venipuncture device. Repeated heparin injections can alter aPTT. ■ To avoid precipitation, irrigate indwelling venipuncture devices with NS before and after injecting acidic or **incompatible** solutions. ■ Heparin and/or NS may interfere with blood samples drawn from these devices, especially if drawn on a frequent basis. Clear the heparin flush solution by aspirating and discarding a volume of solution equal to that of the indwelling venipuncture device before the desired blood sample is drawn.

Patient Education:

Report all episodes of bleeding and apply local pressure if indicated. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping. ■ Promptly report S/S of any other side effects (e.g., hypersensitivity reaction, HIT, HITT).

Maternal/Child:

Use with caution. Maternal and fetal outcomes associated with heparin use during pregnancy have been investigated in numerous studies. These studies generally reported normal deliveries with no maternal or fetal bleeding and no other complications. ■ Not secreted in breast milk. ■ Some preparations may contain benzyl alcohol; do not use in neonates, infants, pregnant women, or breast-feeding mothers; see Contraindications. ■ There are no adequate and well-controlled studies on heparin use in pediatric patients. Pediatric dosing recommendations are based on clinical experience. ■ Use heparin-lock flush with caution in infants with diseases with an increased risk of hemorrhage. The 100 units/mL concentration should not be used in neonates or infants who weigh less than 10 kg because of the risk of systemic anticoagulation. Use minimal doses and preservative-free preparations, and monitor carefully. ■ See Dose Adjustments and Precautions.

Elderly:

Higher plasma levels of heparin and longer aPTTs may occur in patients over 60 years of age. Higher incidence of bleeding in patients 60 years of age and older (especially women). Lower doses of heparin may be indicated; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Increased risk of bleeding with **drugs that can interfere with platelet aggregation and/or increase the risk of bleeding** (e.g., **systemic salicylates** [aspirin], **NSAIDs, platelet aggregation inhibitors, glycoprotein GPIIb/IIIa receptor antagonists, some cephalosporins** [e.g., cefotetan], **dextran, or other thrombolytic agents**); use heparin with caution in patients receiving such agents. ■ Anticoagulant effect of heparin is enhanced by concurrent treatment with **antithrombin III (human)**. ■ Inhibited by **antihistamines, digoxin, nicotine, nitrates, tetracyclines, and others;** may counteract anticoagulant action of heparin. ■ Potentiates **oral anticoagulants** (e.g., apixaban, dabigatran, rivaroxaban, warfarin). ■ See Precautions/Monitor. ■ Use caution when administered with or around **other anticoagulants.** Lab data may not provide an accurate baseline. ■ Numerous **lab values** (e.g., aminotransferase levels [AST, ALT], PT) may be altered. Notify lab of heparin use. Diagnostic results may not be attainable. See Monitor. ■ When heparin is given concomitantly with warfarin, the PT may be prolonged. Wait at least 5 hours after IV bolus heparin dose before drawing PT. If heparin is being administered as a continuous infusion, may draw PT at any time.

SIDE EFFECTS

The most common side effects are elevations of aminotransferase levels and general hypersensitivity reactions, usually chills, fever, and urticaria (anaphylactoid reactions, including shock, asthma, headache, itching and burning on plantar side of feet, lacrimation, nausea and vomiting, and rhinitis may occur less frequently); hemorrhage (bruising, epistaxis, hematuria, tarry stools [adrenal hemorrhage (with resultant acute adrenal insufficiency), ovarian hemorrhage (corpus luteum hemorrhage that may be fatal), and/or retroperitoneal hemorrhage may be difficult to detect]); HIT and HITTS (including delayed-onset cases); injection site irritation; and thrombocytopenia.

ANTIDOTE

Discontinue drug and notify physician of any side effects. Protamine sulfate is a heparin antagonist and specifically indicated in overdose or desired heparin reversal. Each milligram of protamine neutralizes approximately 100 units heparin. No more than 50 mg should be administered, very slowly, in any 10-minute period. Administration of protamine can cause severe hypotension and anaphylactoid reactions. Use with caution and have emergency equipment and medications readily available. If HIT (with or without thrombosis) is diagnosed or strongly suspected, discontinue all sources of heparin, including heparin flushes. Use an alternative anticoagulant. Any future use of heparin should be avoided, especially within 3 to 6 months after the diagnosis of HIT or HITT and while patients test positive for HIT antibodies. Whole blood transfusion may be indicated. If heparin-induced thrombocytopenia or white clot syndrome occurs, discontinue heparin and administer a non-heparin anticoagulant (e.g., argatroban, bivalirudin) as an alternate form of anticoagulation. Follow-up with oral anticoagulation (e.g., warfarin) may also be indicated. Avoid use of heparin for at least 3 to 6 months or for as long as the patient tests positive for HIT antibodies.

HEPATITIS B IMMUNE GLOBULIN INTRAVENOUS (HUMAN)

(hep-ah-**TY-**tiss ih-**MUNE GLAW-**byoo-lin IV)
HepaGam B
Immunizing agent (passive)
pH 5.6

USUAL DOSE (International units [IU])

Pretreatment:

Baseline studies indicated; see Monitor.

Prevention of hepatitis B recurrence following liver transplantation:

Administered by a set dosing regimen designed to attain serum levels of antibodies to hepatitis B surface antigen (anti-HBs) greater than 500 IU/L. Each dose should contain

20,000 IU calculated from the measured potency as stamped on the vial label. Administer the first dose of 20,000 IU concurrently with grafting of the transplanted liver (the anhepatic phase). Administer each subsequent dose of 20,000 IU as recommended in the following chart.

Hepatitis B IGIV Dosing Regimen			
Anhepatic Phase	**Week 1 Postoperative**	**Weeks 2-12 Postoperative**	**Month 4 Onward**
First dose of 20,000 IU	20,000 IU daily from Day 1 through Day 7; see Dose Adjustments	20,000 IU every 2 weeks from Day 14 (Week 2) through Week 12	20,000 IU monthly

DOSE ADJUSTMENTS (International units [IU])

Increased doses may be required in patients who fail to reach anti-HBs levels of 500 IU/L within the first week after liver transplantation. Particularly susceptible to an extensive decrease of circulated anti-HBs are patients who have surgical bleeding or abdominal fluid drainage (greater than 500 mL) or those who undergo plasmapheresis. If the desired anti-HBs levels are not reached, increase the dosing regimen to a half-dose (10,000 IU [calculated from the measured potency as stamped on the vial label]) and administer IV every 6 hours until the target anti-HBs level is reached.

DILUTION

A ready-to-use liquid preparation; should be clear to opalescent. Multiple vials will be required. ***Do not shake vials; avoid foaming.*** Bring to room temperature before administration. Administer through a separate IV line using an IV administration set and an infusion pump.

Filters:

No data available from manufacturer.

Storage:

Store between 2° and 8° C (36° and 46° F). Do not freeze. Do not use after expiration date. Use within 6 hours of opening the vial, and discard partially used vials.

COMPATIBILITY

Manufacturer states, “Administer through a separate IV line using an IV administration set via infusion pump.”

RATE OF ADMINISTRATION

Set infusion pump rate at 2 mL/min. Decrease to 1 mL/min or slower for patient discomfort, infusion-related adverse events, or concern about the speed of infusion.

ACTIONS

A solvent/detergent-treated sterile solution of purified gamma globulin containing anti-

HBs. Prepared from plasma donated by healthy, screened donors with high titers of anti-HBs. Purified by an anion-exchange column chromatography manufacturing method. It provides passive immunization for individuals exposed to the hepatitis B virus by binding to the surface antigen and reducing the rate of hepatitis B infection. Following liver transplantation, hepatitis B virus re-infection can occur immediately at the time of liver reperfusion due to a circulating virus or later from a virus retained in extrahepatic sites. Provides an immediate immune response to the hepatitis B virus. Mechanism of action is not known but may occur through several pathways (e.g., through blockage of a putative HBV receptor, neutralization of circulating virions through immune precipitation and immune complex formation, triggering of an antibody-dependent cell-mediated cytotoxicity response that results in target cell lysis, or binding to hepatocytes and interaction with HBsAg within cells). Clinical effectiveness is dependent on dose, length of administration, and viral replication status of the patient at the time of transplant. Bioavailability is complete and immediate and is distributed quickly between plasma and extravascular fluid. Immune globulins are metabolized by being broken down in the reticuloendothelial system. IM injection results in mean peak concentrations within 4 to 5 days of administration and an elimination half-life of 22 to 25 days. A slightly decreased half-life is expected following IV administration.

INDICATIONS AND USES

Prevention of hepatitis B recurrence following liver transplantation in HBsAg-positive liver transplant patients. Recommended for use in patients who have no or low levels of viral replication at the time of liver transplantation. ■ Used IM for postexposure prophylaxis in the following settings: acute exposure to blood containing HBsAg, perinatal exposure of infants born to HBsAg-positive mothers, sexual exposure to HBsAg-positive persons, and household exposure to persons with acute HBV infection.

CONTRAINDICATIONS

History of anaphylactic or severe systemic reactions to human globulins. ■ Weigh benefits versus risk of hypersensitivity reactions in IgA-deficient individuals; see Precautions.

PRECAUTIONS

Administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Hypersensitivity and/or infusion reactions may occur. ■ Individuals deficient in IgA may have the potential to develop IgA antibodies and have an anaphylactoid reaction. ■ Contains maltose, which can interfere with select blood glucose monitoring systems (those based on the glucose dehydrogenase pyrroloquinequinone [GDH-PQQ] method). May cause falsely elevated glucose readings, result in inappropriate insulin administration, and cause life-threatening hypoglycemia. In contrast, cases of true hypoglycemia may go untreated if the hypoglycemic state is masked by falsely elevated results. ■ Derived from human plasma. Despite screening and purification processes, may have the potential risk of transmitting infectious agents (e.g., viruses [e.g., HIV, hepatitis]) or the Creutzfeldt-

Jakob disease agent. ■ Has not been evaluated in combination with antiviral therapy posttransplantation. ■ See Patient Education and Drug/Lab Interactions.

Monitor:

Hepatitis B IGIV is most effective in patients with no or low levels of HBV replication at the time of transplantation. Monitor serum HBsAg and levels of anti-HBs antibody pre-infusion and regularly to track treatment response and adjust dose when indicated. ■ Infusion reactions may occur; usually related to rate of infusion. Monitor closely during and following an infusion. ■ Use caution and observe diabetic patients closely; see Precautions. Only glucose-specific testing systems can be used in patients receiving hepatitis IGIV. Review product information of the blood glucose testing system to confirm that it can be used with maltose-containing parenteral products. ■ Monitor for S/S of a hypersensitivity reaction.

Patient Education:

Regular monitoring of serum HBsAg and anti-HBs antibody levels imperative. ■ Vaccination with live virus vaccines should be deferred until approximately 3 months after administration of hepatitis B IGIV. Revaccination may be required if the previous vaccination occurred within 2 weeks of the initial hepatitis IGIV dose.

Maternal/Child:

Category C: use during pregnancy only if clearly indicated. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Safety and effectiveness not established.

DRUG/LAB INTERACTIONS

May reduce the effectiveness of **live virus vaccines** (e.g., measles, mumps, rubella, varicella). Vaccination with live virus vaccines should be deferred until approximately 3 months after administration of hepatitis B IGIV. ■ Contains **maltose,** which can interfere with select blood glucose monitoring systems (those based on the glucose dehydrogenase pyrroloquinequinone [GDH-PQQ] method). May cause falsely elevated glucose readings. Use only glucose-specific testing systems in patients receiving hepatitis B IGIV. ■ Passively transferred antibodies may cause a misleading positive result in **serologic testing** (e.g., Coombs' test). ■ No data available on drug interactions with other medications.

SIDE EFFECTS

Arthralgia, chills, fever, headaches, hypersensitivity reactions, moderate or low back pain, nausea, and vomiting are the most common. Other reported side effects include agitation, amnesia, aphthous stomatitis, diarrhea, dyspepsia, edema, fatigue, gingival hyperplasia, hepatobiliary disease, hyperglycemia, hypertension, hypotension, infectious diarrhea, liver transplant rejection, nocturia, pleural effusion, pneumonia, presbyopia, pruritus, rash, sepsis, splenomegaly, tremors.

ANTIDOTE

Reduce rate of infusion for patient discomfort, infusion-related side effects, or other concerns. Discontinue the drug immediately for any signs of a hypersensitivity reaction. Notify the physician. Antihistamines (e.g., diphenhydramine) or analgesic agents may be indicated for symptoms related to immune complex formation. Resume infusion at a slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine, diphenhydramine, corticosteroids, and ventilation equipment must always be available.

HETASTARCH BBW

(**HET**-ah-starch)
Hespan, Hextend
Plasma volume expander
pH 5.5 to 5.9

USUAL DOSE

Hespan, Hextend

Plasma volume expansion:

Variable. Total dosage and rate of administration depend on amount of fluid loss and resultant hemoconcentration. Age, weight, and clinical condition of the patient are also considered. Usually 500 to 1,000 mL. Total dose usually does not exceed 1,500 mL/24 hr for the typical 70-kg patient (approximately 20 mL/kg of body weight). Higher doses, usually in conjunction with blood and/or blood products, have been used in postoperative and trauma patients who have had severe blood loss.

Hespan

Leukapheresis:

250 to 700 mL with citrate anticoagulant in continuous flow centrifugation procedures. Do not use Hextend for leukapheresis.

DOSE ADJUSTMENTS

Avoid use in patients with pre-existing renal impairment. Information on dose adjustment in hepatic impairment is not available.

DILUTION

Hespan:

Available as a 6% solution in 500-mL containers properly diluted in NS and ready for use. Calculated osmolarity is approximately 310 mOsm/L.

Hextend:

Available as a 6% solution in 500-mL containers properly diluted in lactated electrolyte solution and ready for use. Lactated electrolyte solution contains dextrose, normal physiologic levels of calcium and sodium, and slightly lower than normal physiologic levels of potassium and magnesium.

Storage:

Store at CRT. Avoid excessive heat. Do not freeze. Do not use if color is a turbid deep brown or a crystalline precipitate is visible. Discard unused portions.

COMPATIBILITY

Hespan

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

Hextend

Safety and **compatibility** of other additives not established. Contains calcium; do not administer simultaneously through the same administration set as blood; coagulation likely.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Initial 500 mL may be given at rates approaching 20 mL/kg of body weight per hour. If additional hydroxyethyl starch is required, reduce flow to lowest rate possible to maintain hemodynamic status. If pressure infusion is used (flexible containers), withdraw all air through medication port before infusing. If a pumping device is used for administration, discontinue pumping action before the container runs dry or air embolism may result.

Leukapheresis:

Usually infused at a constant ratio to venous whole blood (i.e., 1:8).

ACTIONS

A synthetic colloid solution. Pharmacologically classified as a plasma volume expander. The amount of plasma volume expansion produced approximates that of 5% albumin and decreases over the succeeding 24 to 36 hours. **Hextend** supports oncotic pressure and provides electrolytes. Its electrolyte content resembles that of normal plasma. **Hespan** supports oncotic pressure and increases erythrocyte sedimentation rate. Improves the efficiency of granulocyte collection by centrifugal means. Hetastarch molecules are rapidly eliminated by renal excretion.

INDICATIONS AND USES

Hespan and Hextend:

Treatment of hypovolemia when plasma volume expansion is desired.

Hespan:

Adjunct in leukapheresis to improve harvesting and increase yield of granulocytes.

CONTRAINDICATIONS

Do not use in critically ill adult patients, including patients with sepsis. ■ Severe liver disease. ■ Hypersensitivity to hetastarch. ■ Clinical conditions in which volume overload is a potential problem (such as CHF or renal disease with oliguria or anuria not related to hypovolemia). ■ Pre-existing coagulation or bleeding disorders. ■ **Hextend** contains lactate; not for use in leukapheresis or in the treatment of lactic acidosis.

PRECAUTIONS

Hespan and Hextend:

For IV infusion only. ■ Not a substitute for whole blood or plasma proteins. ■ In critically ill adult patients, including patients with sepsis, the use of hydroxyethyl starch (HES) products, including Hespan and Hextend, increases the risk of mortality and renal replacement therapy. ■ Avoid use in patients with pre-existing renal dysfunction. ■ Discontinue use at the first sign of renal injury. ■ Use caution in heart disease, congestive heart failure, pulmonary edema, and liver disease. ■ Anaphylactic reactions have occurred, even after solutions containing hetastarch have been discontinued. Patients allergic to corn may also be allergic to hetastarch. ■ Administration of large volumes may transiently alter the coagulation mechanism due to hemodilution and a mild direct inhibitory action on factor VIII. Hemodilution by isotonic solutions containing 6% hetastarch may also result in a 24-hour decline of total protein, albumin, and fibrinogen levels and in transient prolongation of prothrombin, activated partial thromboplastin, clotting, and bleeding times. Volumes greater than 25% of blood volume within 24 hours may cause significant hemodilution (decreased hematocrit and plasma proteins). Administration of packed RBCs, platelets, or fresh frozen plasma may be indicated. ■ When used over a period of days, hetastarch has been associated with coagulation abnormalities in conjunction with an acquired reversible von Willebrand's–like syndrome and/or factor VIII deficiency. If a severe factor VIII deficiency is identified, replacement therapy may be indicated. If coagulopathy develops, it may take days to resolve. ■ Not recommended for use as a cardiac bypass pump prime, while the patient is undergoing cardiopulmonary bypass, or in the immediate period after the pump has been discontinued. Risk of coagulopathies and bleeding increased.

Hextend:

Use extreme caution in patients with metabolic or respiratory alkalosis; contains lactate ions. Excessive lactate may result in metabolic alkalosis. ■ Contains electrolytes; use caution in patient populations in which sodium or potassium administration or retention could pose a problem (e.g., renal insufficiency, CHF, hyperkalemia, edema).

Use caution in patients receiving corticosteroids and in renal or cardiac disease, particularly in digitalized patients. ■ Contains dextrose; use caution in patients with overt diabetes.

Monitor:

Hespan and Hextend:

Monitor vital signs, hemoglobin, hematocrit, platelet count, prothrombin time, partial thromboplastin time, and renal and liver function tests. ■ Acid-base balance, electrolytes, and serum protein evaluation are also necessary during therapy. ■ Monitor renal function in hospitalized patients for at least 90 days because the use of renal replacement therapy has been reported up to 90 days after administration of hydroxyethyl starch solutions. ■ May reduce coagulability of the circulating blood. Observe patient for increased bleeding and/or circulatory overload. Risk increased with higher doses.

Hespan:

Monitor donors undergoing repeated leukapheresis procedures; may have a slight decline in platelet count and hemoglobin levels resulting from hemodilution by hetastarch and saline and the collection of platelets and erythrocytes. Temporary declines in total protein, albumin, calcium, and fibrinogen may also be present. Regular and frequent clinical evaluation and complete blood counts are necessary for proper monitoring of Hespan use during leukapheresis. If frequency of leukapheresis is to exceed the guidelines for whole blood donation, additional testing may be indicated; see manufacturer’s prescribing information.

Maternal/Child:

Category C: embryocidal to rabbits. Use only if benefit justifies the potential risk to the fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established, but has been used. Increased prothrombin time noted in pediatric patients who received more than 20 mL/kg/24 hr.

Elderly:

Differences in response between elderly and younger patients not identified. Risk of toxic reactions may be greater in patients with impaired renal function. Monitoring of renal function suggested in the elderly.

DRUG/LAB INTERACTIONS

Use with caution in patients receiving other drugs that affect coagulation (e.g., **anticoagulants, platelet aggregation inhibitors, glycoprotein GPIIb/IIIa receptor antagonists, plicamycin, valproic acid**). Close monitoring of aPTT and PT indicated. ■ May increase **indirect bilirubin** levels. Total bilirubin remained normal. ■ Elevated serum amylase levels have been observed, although no association with pancreatitis has been demonstrated.

SIDE EFFECTS

The most common adverse reactions are circulatory overload, coagulopathy, hemodilution, hypersensitivity (including anaphylaxis), and metabolic acidosis. Anemia and/or bleeding due to hemodilution and/or factor VIII deficiency, acquired von Willebrand's–like syndrome, and other coagulopathies, including DIC; chills; congestive heart failure; elevated serum amylase; fever; headache; increased urine specific gravity; intracranial bleeding; itching; muscle pains; peripheral edema; pulmonary edema; submaxillary and parotid glandular enlargement; urticaria; and vomiting have been reported.

Post-Marketing:

Death, renal failure requiring renal replacement therapy.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Antihistamines such as diphenhydramine are helpful. Epinephrine may also be indicated. Not eliminated by dialysis. Many side effects can result in medical emergencies. Deaths from severe hypersensitivity reactions have occurred. Treat as indicated and resuscitate as necessary.

HYDRALAZINE HYDROCHLORIDE

(hy-**DRAL**-ah-zeen hy-droh-**KLOR**-eyed)
Antihypertensive
Vasodilator
pH 3.4 to 4

USUAL DOSE

10 to 40 mg. Begin with a low dose. Increase gradually as indicated. Repeat every 3 to 6 hours as necessary. Maximum dose is 300 to 400 mg/24 hr.

Eclampsia:

5 to 10 mg every 20 minutes. If no effect after a total dose of 20 mg, use another agent.

PEDIATRIC DOSE

See Maternal/Child (unlabeled).

0.1 to 0.5 mg/kg/dose every 4 to 6 hours. Initial dose should not exceed 20 mg. Maximum IV dose is 0.2 to 0.8 mg/kg/dose up to 40 mg. Another source suggests 0.1 to 0.2 mg/kg/dose (not to exceed 20 mg) every 4 to 6 hours as needed. Up to 1.7 to 3.5 mg/kg/day divided in 4 to 6 doses.

DOSE ADJUSTMENTS

Reduced dose may be required with advanced renal disease and in the elderly. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set. Color changes occur in most 10% dextrose solutions and after drawing through a metal filter. Use immediately after drawing up solution.

Filters:

See Dilution.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adults:

A single dose over 1 minute.

Pediatric patients:

A single dose over 3 to 5 minutes.

ACTIONS

A potent antihypertensive drug. It lowers BP by direct relaxation of smooth muscle of arteries and arterioles. Peripheral vasodilation and decreased peripheral vascular resistance result. HR, cardiac output, and stroke volume are all increased. Renal blood flow increased in some cases, while cerebral blood flow maintained. Onset of action is 5 to 20 minutes. Average duration of action is 2 to 6 hours. Metabolized by the liver and excreted in urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Severe essential hypertension. ■ Vasodilation in cardiogenic shock. ■ Drug of choice for pregnancy-induced hypertension (eclampsia).

CONTRAINDICATIONS

Hypersensitivity to hydralazine, coronary artery disease, mitral valvular rheumatic heart disease.

PRECAUTIONS

IV use recommended only when the oral route is not feasible. ■ Rarely the drug of choice for hypertension unless used in combination (effectiveness increased and side effects decreased) with spironolactone, reserpine, guanethidine, and thiazide diuretics. ■ Tolerance is easily developed but subsides about 7 days after the drug is discontinued. ■ Use caution in advanced renal disease, cerebrovascular accidents, congestive heart failure, coronary insufficiency, headache, increased intracranial pressure, and tachycardia. ■ Use in pregnancy should be limited to treatment of eclampsia.

Monitor:

Check BP every 5 minutes until stabilized at the desired level. Check every 15 minutes thereafter throughout crisis. Average maximum decrease occurs in 10 to 80 minutes. ■ Withdraw drug gradually to avoid rebound hypertension.

Patient Education:

Report chest pain, fatigue, fever, joint or muscle pain promptly.

Maternal/Child:

Category C: can cause fetal abnormalities; see Indications and Precautions. ■ Safety for use in pediatric patients not established. ■ May be used in breast-feeding women.

Elderly:

Increased risk of hypotension. ■ Consider age-related renal impairment.

DRUG/LAB INTERACTIONS

Sometimes used with a **beta-adrenergic blocking drug or diuretics**; use caution; may potentiate effects. ■ Potentiated by **anesthetics, MAO inhibitors, and other antihypertensive agents**. ■ Inhibits **epinephrine, levarterenol**. ■ Use with **diazoxide** can cause profound hypotension. ■ **NSAIDs** may decrease antihypotensive effect.

SIDE EFFECTS

May often be minimized by initiating therapy with a small dose and increasing the dose gradually.
Anxiety, depression, dry mouth, flushing, headache, nausea, numbness, palpitations, paresthesia, postural hypotension, tachycardia, tingling, unpleasant taste, vomiting.

Major:

Angina, blood dyscrasias, chills, coronary insufficiency, delirium, dependent edema, fever, ileus, lupus erythematosus (simulated), myocardial ischemia and infarction, rheumatoid syndrome (simulated), toxic psychosis.

ANTIDOTE

If minor side effects occur, notify the physician, who will probably treat them symptomatically. Beta-adrenergic blocking agents will control tachycardia. Pyridoxine will relieve numbness, tingling, and paresthesia. Antihistamines, barbiturates, and salicylates may be required. Treat hypotension with a vasopressor that is least likely to precipitate cardiac arrhythmias. If side effects are progressive or any major side effects occur, discontinue the drug immediately and notify the physician. Treatment is symptomatic. Resuscitate as necessary. Occasionally methyldopa will be used as a substitute because it is effective for the same indications but has fewer side effects.

HYDROCORTISONE SODIUM SUCCINATE

(hy-droh-**KOR**-tih-zohn **SO**-dee-um **SUK**-sih-nayt)
A-Hydrocort, Solu-Cortef
Hormone (corticosteroid)
Anti-inflammatory
pH 7 to 8

USUAL DOSE

Average dose range is 100 to 500 mg repeated as necessary every 2, 4, or 6 hours depending on patient condition and response. Dosage must be individualized. The IV route is usually used in an emergency situation or when oral dosing is not feasible. Larger doses may be justified by patient condition (doses as high as 8 Gm/day can be found in the literature). High-dose treatment is used until patient condition stabilizes, usually no longer than 48 to 72 hours. When high-dose hydrocortisone therapy must be continued beyond 48 to 72 hours, hypernatremia may occur. Under such circumstances it may be desirable to substitute with a corticoid such as methylprednisolone sodium succinate, which causes little or no sodium retention. Once an adequate clinical response has been achieved, slowly taper dosage downward, using the lowest possible dose required to maintain that response.

Life-threatening shock:

50 mg/kg initially. Repeat in 4 hours and/or every 24 hours as needed *or*
0.5 to 2 Gm initially. Repeat every 2 to 6 hours as needed.

Adrenal insufficiency (acute):

100 mg as an IV bolus. Follow with 200 mg over 24 hours as a continuous IV infusion or in divided doses every 6 hours, then 100 mg over 24 hours the following day. Change to oral dosing when patient is stable. *See literature for additional dosing regimens in use.*

PEDIATRIC DOSE

See Maternal/Child. Dose should be based on the severity of the disease and on patient response rather than on strict adherence to a dose indicated by age, weight, or body surface area.

Average dose range in pediatric patients is 0.56 to 8 mg/kg/day in 3 to 4 divided doses (0.19 to 2.67 mg/kg every 8 hours or 0.14 to 2 mg/kg every 6 hours).

Other sources recommend:

Status asthmaticus:

Loading dose (optional):

4 to 8 mg/kg up to a maximum dose of 250 mg.

Maintenance dose:

8 mg/kg/24 hr in equally divided doses every 6 hours (2 mg/kg every 6 hours).

Anti-inflammatory:

1 to 5 mg/kg/24 hr, or 0.5 to 2.5 mg/kg every 12 hours, or 30 to 150 mg/M^2/24 hr, or 15 to 75 mg/M^2 every 12 hours.

DOSE ADJUSTMENTS

Use lowest possible dose required to control condition being treated. When dose reduction is possible, decrease dose gradually while monitoring for S/S of disease exacerbation. ■ Because complications of treatment with glucocorticoids depend on dose and duration of therapy, a risk/benefit decision must be made for each patient regarding dose and duration of treatment and whether daily or intermittent therapy should be used. ■ Clearance of corticosteroids is decreased in patients with hypothyroidism and increased in patients with hyperthyroidism. Dose adjustment may be required. ■ See Drug/Lab Interactions.

DILUTION

Available in Act-O-Vials, which are reconstituted by pressing down on the plastic activator to force diluent into the lower compartment. Agitate gently. Remove plastic tab covering center of stopper. Sterilize top of stopper, then insert needle squarely through center of stopper until tip is just visible. Invert vial and withdraw dose. Also available in flip-top vials. For these other preparations, reconstitute each 100 mg with not more than 2 mL bacteriostatic water for injection. Agitate gently to mix solution. May be given by IV injection, or each 100 mg (250 mg, 500 mg, or more) may be further diluted in at least 100 mL (250 mL, 500 mL, or more) but not more than 1,000 mL of D5W, NS, or D5NS to a concentration of 0.1 to 1 mg/mL for IV infusion.

Storage:

Store vials and solutions at RT (20° to 25° C [68° to 77° F]). Protect solution from light. Discard unused solutions after 3 days. If fluid restriction is necessary, 100 to 3,000 mg may be added in 50 mL of **compatible** solution. Resultant solution is stable for at least 4 hours.

COMPATIBILITY

Manufacturer states, “Should not be diluted or mixed with other solutions.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 100 mg or fraction thereof over 30 seconds to 1 minute. Extend to 10 minutes for larger doses (500 mg or more). IV injection is usually the route of choice and eliminates the possibility of overloading the patient with IV fluids. At the discretion of the physician, an intermittent or continuous infusion may be given, properly diluted over the specified time desired.

ACTIONS

An anti-inflammatory glucocorticoid secreted by the adrenal cortex. Has both glucocorticoid and mineralocorticoid properties. Glucocorticoids cause profound and varied metabolic effects. In addition, they modify the body's immune response to diverse stimuli. Peak plasma levels achieved promptly. Onset of action is within 1 hour. Metabolized in the liver and excreted as inactive metabolites in the urine. Elimination half-life is 2 hours. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Agent of choice for replacement therapy in adrenocortical insufficiency because it has both glucocorticoid and mineralocorticoid activity. ■ May be used for acute exacerbation of disease for patients on steroid therapy. ■ Because of their minimal mineralocorticoid activity, synthetic glucocorticoids (e.g., dexamethasone, methylprednisolone) are the preferred agents for anti-inflammatory or immunosuppressive indications. ■ May be used for the treatment of various diseases or disorders, including allergic states, dermatologic diseases, endocrine disorders, GI diseases, hematologic disorders, neoplastic diseases, nervous system disorders, ophthalmic diseases, renal diseases, respiratory diseases, or rheumatic disorders; see manufacturer's prescribing information.

CONTRAINDICATIONS

Hypersensitivity to hydrocortisone or any of the product components. ■ Cerebral malaria (no evidence of benefit). ■ Systemic fungal infections. ■ Intrathecal administration. ■ IM administration for idiopathic thrombocytopenic purpura.

PRECAUTIONS

Corticosteroids can produce reversible hypothalamic-pituitary-adrenal (HPA) axis suppression with the potential for glucocorticosteroid insufficiency after withdrawal of treatment. Adrenocortical insufficiency may result from too-rapid withdrawal of corticosteroids and may be minimized by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore hormone therapy should be reinstituted in any situation of stress occurring during that period (e.g., surgery, trauma, infection). If the patient is receiving steroids already, dosage may need to be increased. The exception is very short-term therapy. ■ Anaphylactoid reactions have occurred (incidence is rare). ■ Should not be used for treatment of traumatic brain injury. May increase mortality. ■ Hypertension, sodium and water retention, and potassium and calcium excretion can occur with average to large doses of corticosteroids. Dietary sodium restriction and potassium supplementation may be necessary. Caution and close monitoring required in patients with existing cardiovascular disease or renal insufficiency. ■ Use with caution in patients who have had a recent MI. May be associated with left ventricular free wall rupture. ■ Prolonged use of corticosteroids may increase susceptibility to infection, reactivate latent infectious diseases, or mask signs of infection. ■ Infections such as chickenpox and measles can have a more serious or even fatal course in pediatric and adult patients on corticosteroids. Patients who have not had these diseases should take care to avoid exposure. If exposed, therapy with varicella zoster immune globulin

(VZIG) or IVIG may be indicated. If chickenpox develops, treatment with antiviral agents should be considered. ■ Corticosteroids should be used with great caution in patients with known or suspected Strongyloides (threadworm) infestation. Corticosteroid-induced immunosuppression may lead to Strongyloides hyperinfection and dissemination with widespread larval migration, often accompanied by severe enterocolitis and potentially fatal gram-negative sepsis. ■ The use of corticosteroids in patients with active tuberculosis should be restricted to cases of fulminating or disseminated tuberculosis in which the corticosteroid is being used for disease management in conjunction with an appropriate antituberculosis regimen. ■ If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, reactivation of the disease may occur. During prolonged corticosteroid therapy, chemoprophylaxis is indicated. ■ Prolonged use of corticosteroids may produce posterior subcapsular cataracts or glaucoma with possible damage to the optic nerves and may enhance the establishment of secondary ocular infections due to fungi or viruses. ■ Use with caution in patients with ocular herpes simplex; corneal perforation can occur ■ Kaposi's sarcoma has been reported in patients receiving corticosteroid therapy, most often for chronic conditions. Clinical improvement may occur if therapy is discontinued. ■ Use with caution in patients with active or latent peptic ulcer disease, diverticulitis, fresh intestinal anastomoses, and nonspecific ulcerative colitis; may increase risk of perforation. ■ Use with caution in cirrhosis; effect of corticosteroids may be enhanced due to decreased metabolism. ■ May induce psychological side effects (e.g., euphoria, insomnia, mood swings, depression, psychosis) or may aggravate existing emotional instability or psychotic tendencies. ■ An acute myopathy has been reported with the use of high doses of corticosteroids, most often in patients with disorders of neuromuscular transmission (e.g., myasthenia gravis) or in patients receiving concomitant therapy with neuromuscular blocking agents. This myopathy is generalized, may involve ocular and respiratory muscles, and may result in quadriparesis. Improvement or recovery after stopping corticosteroids may take weeks to years. ■ Use with caution in patients at risk for osteoporosis. Corticosteroids decrease bone formation, increase bone resorption, and decrease the protein matrix of the bone. May lead to inhibition of bone growth in pediatric patients and the development of osteoporosis at any age. ■ Pheochromocytoma crisis, which can be fatal, has been reported. Use caution and consider risk in patients with suspected pheochromocytoma.

Monitor:

Monitor electrolytes. May cause sodium retention and potassium and calcium excretion. Dietary salt restriction and potassium supplementation may be necessary. BP monitoring may be indicated; may cause hypertension secondary to fluid and electrolyte disturbances. ■ Monitor for S/S of infection; S/S may be masked. ■ Patients with latent tuberculosis should be monitored for reactivation of the disease. ■ Monitor blood glucose. May increase insulin needs in diabetes. ■ Periodic ophthalmic exams may be necessary with prolonged treatment. ■ Monitor for S/S of a hypersensitivity reaction. ■ Elevation of creatine kinase may occur with acute myopathy. Monitor if indicated. ■ See Drug/Lab Interactions.

Patient Education:

Do not discontinue abruptly. ■ Advise all medical personnel of current or past corticosteroid use. ■ Report edema, tarry stools, or weight gain promptly. Anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, and vomiting may indicate adrenal insufficiency after dose reduction or discontinuation of therapy; report any of these symptoms. ■ May mask signs of infection and/or decrease resistance. ■ Patients with diabetes may have an increased requirement for insulin or oral hypoglycemics. ■ Avoid immunization with live virus vaccines. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child:

Category C: use with caution; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Observe newborn for hypoadrenalism if mother has received large doses. ■ Observe growth and development in long-term use in pediatric patients.

Elderly:

Use cautiously in the smallest possible dose. ■ Monitor BP, blood glucose, and electrolytes carefully. ■ Higher risk of glucocorticoid-induced osteoporosis.

DRUG/LAB INTERACTIONS

Aminoglutethimide may increase the metabolism of hydrocortisone, thereby decreasing therapeutic effects. ■ Metabolism increased and effects reduced by **hepatic enzyme–inducing agents** (e.g., alcohol, barbiturates, phenytoin, and rifampin); dose adjustment may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B or potassium-depleting diuretics** (e.g., thiazides, furosemide). Monitor potassium levels and cardiac function. ■ Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May also decrease effectiveness of **potassium supplements;** monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease sodium excretion and diuretic effects of diuretics. ■ May enhance the adverse/toxic effects of **anticholinesterases** (e.g., neostigmine); increased weakness may occur. ■ May decrease effectiveness of **isoniazid**, **salicylates, and somatrem;** dose adjustments may be required. ■ Clearance decreased and effects increased with **estrogens, oral contraceptives, macrolide antibiotics** (e.g., azithromycin), **and ketoconazole**. ■ May interact with **anticoagulants, nondepolarizing muscle relaxants, or theophyllines;** may inhibit or potentiate action. ■ Carefully monitor patients receiving **insulin**; dose adjustments may be required. ■ Increased activity of both **hydrocortisone and cyclosporine** may occur with concurrent use; convulsions have been reported. ■ Concurrent use with **aspirin or NSAIDs** may increase the risk of GI side effects. ■ Administration of **live or live-attenuated vaccines** is contraindicated in patients receiving immunosuppressive dose of corticosteroids. Inactivated vaccines may be administered; however, the response to these vaccines cannot be predicted. ■ **Corticosteroids** may suppress reactions to skin tests. ■ See Dose Adjustments.

SIDE EFFECTS

Do occur but are usually reversible: alteration of glucose metabolism including hyperglycemia and glycosuria; Cushing's syndrome (e.g., moon face, fat pads); electrolyte and calcium imbalance; euphoria or other psychic disturbances; fluid retention; hypersensitivity reactions, including anaphylaxis; impaired wound healing; increased BP; increased intracranial pressure; leukocytosis; masking of infection; menstrual irregularities; perforation and hemorrhage from aggravation of peptic ulcer; ophthalmic disorders (glaucoma, increased intraocular pressure); protein catabolism with negative nitrogen balance; spontaneous fractures; sweating, headache, or weakness; thromboembolism; transitory burning or tingling; and many others.

ANTIDOTE

Notify the physician of any side effect. Will probably treat the side effect if necessary. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

HYDROMORPHONE HYDROCHLORIDE BBW

(hy-droh-**MOR**-fohn hy-droh-**KLOR**-eyed)
Dilaudid, Dilaudid HP
Opioid analgesic (agonist)
pH 3.5 to 5.5, 4.5 to 6.5

USUAL DOSE

Individualize dose, taking into account the patient's severity of pain, response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient's treatment goals. **Hydromorphone is approximately 7 times more potent than morphine.**

Dispense with caution; dosing errors due to confusion between different concentrations and between mg and mL could result in accidental overdose and death. Never administer hydromorphone-HP to an opioid-naïve patient. Oral and IV doses of hydromorphone and IV doses with doses of other opioids are ***NOT*** equivalent; see prescribing information for a discussion on opioid conversion and equianalgesic potency for conversion to hydromorphone injection.

IV injection:

Usual starting dose is 0.2 to 1 mg every 2 to 3 hours as needed for pain. Titrate dose to achieve acceptable pain management and tolerable adverse events.

Infusion (unlabeled):

Used postoperatively with a patient-controlled analgesic device (PCA) and in selected terminally ill cancer patients. One source suggests a concentration of 0.2 mg/mL, with a starting patient-controlled dose of 0.2 mg (range 0.05 to 0.4 mg) that can be activated at prescribed intervals. Must be administered through a controlled infusion device that may be patient activated. The initial loading dose, the continuous background infusion (if prescribed), additional patient-activated doses with a specific time interval, additional health care professional–provided boluses with a specific time interval, and the total dose allowed per hour must be determined by the physician and individualized for each patient.

PEDIATRIC DOSE

Individualized on the basis of age and weight (unlabeled). One source suggests 0.015 mg/kg/dose every 4 to 6 hours as needed in pediatric patients; see Contraindications and Maternal/Child.

DOSE ADJUSTMENTS

Dose selection should be cautious in elderly, cachectic, and debilitated patients. Reduced initial doses may be indicated based on the potential for increased sensitivity, decreased organ function, and concomitant disease or drug therapy. ■ Depending on the degree of impairment, one-fourth to one-half the usual starting dose is recommended in patients with impaired renal or hepatic function. ■ Use lower initial doses in opiate-naïve patients. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■ Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ Decrease dose if excessive side effects are observed early in the dosing interval. If this results in breakthrough pain at the end of the dosing interval, the dosing interval may be shortened. ■ See Drug/Lab Interactions.

DILUTION

Available in more than one concentration (1 mg/mL, 2 mg/mL, and 4 mg/mL) and hydromorphone-HP (a high-potency [10 mg/mL]) formulation. Do not confuse hydromorphone-HP with standard formulations of hydromorphone or other opioids; overdose and death could result. Hydromorphone-HP is usually reserved for compounding in the pharmacy or for use in opioid-tolerant patients. Verify concentration to avoid overdose and/or death.

IV injection:

May be given undiluted. May give through Y-tube or three-way stopcock of infusion set.

Infusion:

Each 0.1 to 1 mg is usually diluted in 1 mL NS to provide 0.1 to 1 mg/mL for use in a narcotic syringe infuser system. Dilaudid is available in 1-, 2-, or 4-mg/mL clear ampules. Dilaudid-HP is available in 10-mg/mL amber ampules and as lyophilized powder that must be reconstituted with 25 mL SWFI for a concentration of 10 mg/mL. Generic hydromorphone is available in similar concentrations; check mg/mL carefully. Use concentrated preparations for larger doses. May be diluted in larger amounts of D5W, D5NS, D5/½NS, or NS for infusion and given through a standard infusion pump (requires very close titration).

Storage:

Store unopened product at CRT and protect from light and freezing. May develop a slight yellowish discoloration. No loss of potency has been demonstrated. Stable for 24 hours at 25° C (77° F), protected from light, in most common large-volume parenteral solutions.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Rapid IV administration increases the possibility of hypotension and respiratory depression.

IV injection:

Administer a single dose over a minimum of 2 to 3 minutes. Frequently titrated according to symptom relief and respiratory rate.

Infusion:

All parameters (outlined in Usual Dose) should be ordered by the physician. Any dose requiring a controlled infusion device requires accurate titration and close monitoring.

ACTIONS

A mu-opioid receptor agonist closely related to morphine. Precise mode of action is unknown, but opioids are believed to combine with specific CNS opiate receptors. The principal therapeutic action of hydromorphone is analgesia. Seven times more potent than morphine milligram for milligram. Produces respiratory depression by direct effect on brainstem respiratory centers and reduces the responsiveness to increases in carbon dioxide. Onset of action is prompt, and half-life is about 2.3 hours. Hydromorphone is metabolized in the liver and excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Hydromorphone (1 mg/mL, 2 mg/mL, or 4 mg/mL):

Management of pain severe enough to require an opioid analgesic and for which alternate treatments are inadequate.

High-potency hydromorphone (10 mg/mL):

For use in opioid-tolerant patients who require higher doses of opioids for the management of pain severe enough to require an opioid analgesic and for which alternate treatments are inadequate. Patients considered opioid-tolerant are those who are taking at least 60 mg oral morphine/day, 25 mcg transdermal fentanyl/hr, 30 mg oral oxycodone/day, 8 mg hydromorphone/day, 25 mg oral oxymorphone/day, 60 mg hydrocodone/day, or an equianalgesic dose of another opioid around-the-clock for 1 week or longer.

Limitations of use:

Because of the risk of addiction, abuse, and misuse, even at recommended doses, reserve hydromorphone for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated
- Have not provided adequate analgesia or are not expected to provide adequate analgesia

CONTRAINDICATIONS

Hypersensitivity to hydromorphone, any of its components, or sulfite-containing medications. ■ Significant respiratory depression. ■ Acute or severe bronchial asthma in the absence of resuscitation equipment or in unmonitored settings. ■ In patients with known or suspected GI obstruction, including paralytic ileus. ■ Hydromorphone-HP is contraindicated in patients who are not opioid tolerant.

PRECAUTIONS

Hydromorphone-HP is a more concentrated solution of hydromorphone that is for use in opioid-tolerant patients only. Do not confuse hydromorphone-HP formulations with standard formulations of hydromorphone or with other opioids; overdose and death could result. ■ Hydromorphone exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing hydromorphone, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that utilize hydromorphone and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Serious, life-threatening, or fatal respiratory depression may occur with the use of hydromorphone. Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), resuscitative and intubation equipment, and oxygen should be readily available. ■ Use with extreme caution in patients with COPD, cor pulmonale, a substantially decreased respiratory reserve, hypoxia, hypercapnia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea, even at recommended doses. Consider using nonopioid analgesics, or administer under careful medical supervision at the lowest effective dose. ■ Use with caution and reduce initial doses in elderly, cachectic, or debilitated patients and in patients with severe impairment of hepatic, pulmonary, or renal function. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. Avoid use in patients with impaired consciousness or coma ■ May cause severe hypotension in postoperative patients or in any patient whose ability to maintain blood pressure has been compromised by a depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines). In patients with circulatory shock, hydromorphone-induced vasodilation may further reduce cardiac output and blood pressure. Use should be avoided; see Drug/Lab Interactions. ■ May produce orthostatic hypotension in ambulatory patients. ■ Cases of serotonin syndrome have been reported during concomitant use of fentanyl with serotonergic drugs. ■ Cases of adrenal insufficiency have been reported with opioid use, more often after more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried; some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ Symptoms of acute abdominal conditions may be masked. Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ May increase the frequency of seizures in patients with a convulsive disorder and may induce or aggravate seizures in some clinical settings. ■ Do not abruptly discontinue hydromorphone in a patient who is physically dependent; dose must be tapered gradually. ■ Some products may use a latex stopper and some may contain sulfites; may cause a hypersensitivity reaction in susceptible patients. ■ See Drug/Lab Interactions and Maternal/Child.

Monitor:

Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. Oxygen, naloxone, and equipment to establish and maintain an airway must be available. ■ Assess baseline pain, reassess after administration of hydromorphone, and adjust dose or interval as required. ■ Monitor vital signs and oxygenation and observe patient frequently. ■ Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Laxatives with or without stool softeners will be required to avoid constipation and fecal impaction, especially with increased doses and extended use. Maintain adequate hydration.

Patient Education:

Avoid alcohol or other CNS depressants. Review all medications for interactions. ■ May cause blurred vision, drowsiness, or dizziness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ Report unrelieved pain or unacceptable side effects promptly. ■ Promptly report S/S of serotonin syndrome. ■

May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the risk to the fetus. ■ Use during labor and delivery may produce respiratory depression and a physiologic effect in neonates. May also prolong labor by reducing the strength, duration, and frequency of contractions. Closely monitor neonates exposed to hydromorphone during labor and delivery for signs of excessive sedation and respiratory depression. ■ Prolonged use of hydromorphone during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. Infants born to mothers receiving hydromorphone during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome, if indicated. See literature for treatment protocols. Infants born to mothers physically dependent on opioids will also be physically dependent and may exhibit respiratory difficulties and withdrawal symptoms (e.g., excessive crying, fever, hyperactive reflexes, increased respiratory rate, increased stools, sneezing, tremors, vomiting, yawning). ■ Use caution with breast-feeding. Monitor infants exposed to hydromorphone through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety and effectiveness for use in pediatric patients not established. ■ Pediatric patients may be more sensitive to effects (e.g., respiratory depression).

Elderly:

See Dose Adjustments and Precautions. ■ May be more susceptible to effects (e.g., respiratory depression, urinary retention, constipation). Respiratory depression is the chief risk for elderly patients treated with opioids. ■ Lower doses may provide effective analgesia.

DRUG/LAB INTERACTIONS

Concomitant use of hydromorphone with **benzodiazepines** and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required, and monitor patients carefully for S/S of respiratory depression and sedation. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including hydromorphone, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of hydromorphone is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. If urgent use of an opioid is necessary, use test doses and frequent titration of small doses to treat pain while closely monitoring BP and S/S of CNS and respiratory depression. ■ **Mixed agonist/antagonist analgesics and partial agonists** may reduce the analgesic effect of hydromorphone and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Hydromorphone may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus.

SIDE EFFECTS

The most frequently occurring side effects include dizziness, dry mouth, dysphoria, euphoria, flushing, light-headedness, nausea, pruritus, sedation, sweating, and vomiting. Serious adverse reactions include respiratory depression and apnea and, to a lesser extent, circulatory depression, respiratory arrest, shock, and cardiac arrest. Other side effects may include abnormal dreams; agitation; alteration of moods; anorexia; antidiuretic effects; anxiety; arrhythmias (e.g., bradycardia, palpitations, tachycardia); biliary colic; blurred or impaired vision; bronchospasm; chills; depression; disorientation and hallucination; drug abuse, addiction, and dependence; GI effects (e.g., abdominal pain, constipation, diarrhea, ileus) and effects in sphincter of Oddi; headache; hypotension; increased intracranial pressure; injection site pain and urticaria; insomnia; laryngospasm; miosis; muscle rigidity; nervousness; nystagmus; paresthesia; rash; seizures; shock; taste alteration; tremor; urinary retention or hesitancy; weakness.

Overdose:

Apnea, atypical snoring, bradycardia, cardiac arrest, circulatory depression or collapse, cold and clammy skin, constricted pupils, hypotension (severe), partial or complete airway obstruction, respiratory depression or arrest, skeletal muscle flaccidity, somnolence progressing to stupor or coma, and death.

Post-Marketing:

Anaphylactic reactions, confused state, convulsions, dyskinesia, dyspnea, erectile dysfunction, increased hepatic enzymes, hyperalgesia, hypersensitivity reactions, injection site reactions, myoclonus, oropharyngeal swelling, peripheral edema, and somnolence.

ANTIDOTE

Notify the physician of any side effect. If minor side effects progress or any major side effect occurs, including the onset of symptoms of overdose, discontinue the drug and notify the physician. Naloxone will reverse serious cardiovascular, CNS, and respiratory reactions. Naloxone use should be reserved for situations in which clinically significant respiratory or circulatory depression is present. Titrate naloxone dose carefully to avoid precipitating an acute abstinence syndrome or uncontrolled pain. The duration of action of hydromorphone may exceed the duration of action of naloxone. Monitor patient carefully. Repeat doses of naloxone may be required. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat anaphylaxis as indicated or resuscitate as necessary.

HYDROXOCOBALAMIN

(hy-**DROX**-oh-koh-**BAL**-ah-min)
Cyanokit
Antidote
pH 3.5 to 6

USUAL DOSE

Pretreatment:

Baseline assessment required and baseline studies helpful; see Precautions and Monitor. Manufacturer provides a quick-use reference guide in carton to facilitate immediate administration. It covers reconstitution, mixing, infusion rate, common S/S of cyanide poisoning with or without smoke inhalation, **incompatibilities,** and alternate diluents.

Initial dose:

5 Gm administered by IV infusion over 15 minutes. Based on severity of poisoning and clinical response, a second 5-Gm dose may be administered for a total dose of 10 Gm.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established but has been used outside the United States.

Initial dose (unlabeled):

70 mg/kg.

DOSE ADJUSTMENTS

No dose adjustments required in the elderly. ■ Potential need for dose adjustment in patients with impaired hepatic or renal function has not been studied.

DILUTION

Each kit contains one 5-Gm, 250-mL glass vial of lyophilized hydroxocobalamin, a sterile transfer spike, a sterile vented infusion tubing, a quick-use reference guide, and a package insert. The glass vial is marked with a fill line for diluent. Using a sterile spike, transfer 200 mL of NS diluent into the glass vial (to the fill line [25 mg/mL]). If NS is not available, LR or D5W may be used. ***Do Not Shake!*** Invert or rock vial for a least 60 seconds to mix. Solution should be clear and dark red. Attach infusion tubing and begin infusion of the first vial; see Rate of Administration.

Filters:

Specific information not available.

Storage:

Store kit at CRT. See package insert for allowable storage temperatures for kit transport in extreme weather conditions. Reconstituted product may be held at a temperature not to exceed 40° C (104° F) for up to 6 hours. Do not freeze. Discard any unused portion after 6 hours.

COMPATIBILITY

Manufacturer lists as **incompatible** with ascorbic acid, blood products (whole blood, packed red cells, platelet concentrate, and/or fresh frozen plasma), diazepam (Valium), dobutamine, dopamine, fentanyl, nitroglycerin IV, pentobarbital (Nembutal), propofol (Diprivan), sodium nitrite, sodium thiosulfate. Do not administer simultaneously through the same IV line. Use of a separate line on the opposing extremity is recommended. The safety of administering other cyanide antidotes simultaneously with hydroxocobalamin has not been established; if used ***Do not administer*** through the same IV lines; see preceding comment.

RATE OF ADMINISTRATION

Each 5-Gm dose properly diluted and evenly distributed over 15 minutes. The rate of infusion for the second 5-Gm dose may range from 15 minutes (for a patient in extremis) to 2 hours based on patient condition.

ACTIONS

A high dose of cyanide can result in death within minutes by inhibiting the cells' ability to use oxygen (inhibition of cytochrome oxidase results in arrest of cellular respiration). Specifically, cyanide binds with a component of cytochrome oxidase (cytochrome a3), prevents the cell from using oxygen, and forces anaerobic metabolism; this results in lactate production, cellular hypoxia, and metabolic acidosis. Each molecule of hydroxocobalamin can bind one cyanide ion to form cyanocobalamin (vitamin B_{12}) and reverse the toxic process. Cyanocobalamin is then excreted in urine.

INDICATIONS AND USES

Treatment of known or suspected cyanide poisoning. Administer without delay if clinical suspicion of cyanide poisoning is high. Symptoms of cyanide poisoning include chest tightness, confusion, dyspnea, headache, nausea. Signs of cyanide poisoning include altered mental status (e.g., confusion, disorientation), seizures or coma, mydriasis (excessive dilation of the pupil of the eye), abnormally rapid or deep breathing (early), abnormally slow breathing or apnea (late), hypertension (early), hypotension (late), cardiovascular collapse, vomiting, plasma lactate concentration equal to or greater than 8 mmol/L. Smoke inhalation victims with cyanide poisoning have usually been exposed to fire and smoke in an enclosed area and may present with soot around mouth, nose, and/or oropharynx or an altered mental status. They may have a plasma lactate concentration equal to or greater than 10 mmol/L.

CONTRAINDICATIONS

Manufacturer states, “None”; see Precautions.

PRECAUTIONS

For IV use only. ■ If clinical suspicion of cyanide poisoning is high, administer hydroxocobalamin without delay. ■ In addition to treatment with hydroxocobalamin, immediate confirmation of airway patency, adequacy of oxygenation and hydration, cardiovascular support (may be hypotensive or hypertensive), and management of seizure activity is required. Decontamination measures may also be indicated. ■ Use caution in patients with known hypersensitivity to hydroxocobalamin or cyanocobalamin (vitamin B_{12}). Consider alternative treatments if available (e.g., sodium nitrite and sodium thiosulfate). ■ Acute renal failure with acute tubular necrosis, renal impairment, and urine calcium oxalate crystals has occurred. In some cases, hemodialysis was required to achieve recovery. ■ Collection of a pretreatment blood sample would be useful in confirming a diagnosis of cyanide poisoning but should not delay treatment. ■ May cause photosensitivity. ■ Use in patients with impaired hepatic or renal function has not been studied. ■ See Drug/Lab Interactions.

Monitor:

Immediately confirm airway patency, adequacy of oxygenation, and adequate hydration. ■ If feasible, draw a pretreatment blood sample; see Precautions. ■ Monitor BP (may be hypotensive or hypertensive [BP equal to or greater than 180 mm Hg systolic or equal to or greater than 110 mm Hg diastolic has been reported with this treatment]). Hypertension may occur at the beginning of the infusion, is usually at a maximum by the end of the infusion, and should return to baseline within 4 hours. Note Compatibility if treatment is required. ■ Monitor for seizures. Note Compatibility if treatment is required. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, angioneurotic edema, chest tightness, dyspnea, edema, pruritus, rash, urticaria). ■ Regular monitoring of renal function, including but not limited to BUN and serum creatinine, should be performed for 7 days after treatment.

Patient Education:

Skin redness may last up to 2 weeks. Avoid sun exposure while skin is red. ■ Urine redness may last up to 5 weeks. ■ An acne-like rash may appear 7 to 28 days after treatment. Has usually resolved without treatment. ■ Renal function will be monitored for 7 days after treatment or, in the event of renal impairment, until renal function returns to normal. ■ Discontinue breast-feeding; talk with your physician to see when and if you can resume. ■ Notify provider if pregnant during therapy. ■ Report any side effect that is troublesome or doesn’t go away.

Maternal/Child:

Has caused skeletal and soft tissue abnormalities, including alterations in the CNS in animal studies. Cyanide readily crosses the placenta. Cyanide poisoning can be fatal for the pregnant woman and fetus if left untreated; life-sustaining therapy should not be withheld due to pregnancy. ■ Breast-feeding is not recommended during treatment. ■ Safety and effectiveness for use in pediatric patients not established but has been used outside the United States.

Elderly:

Safety and effectiveness similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ **Sodium nitrite and sodium thiosulfate** are also used to treat cyanide poisoning. They are **incompatible** with hydroxocobalamin and must be administered in a separate IV line if used concurrently. Safety of coadministration has not been established. ■ Because of its deep red color, hydroxocobalamin **interferes with numerous clinical laboratory tests.** Effects persist for varying lengths of time depending on test. See package insert for specifics. ■ Deep red color may cause hemodialysis machines to shut down (an erroneous detection of a “blood leak”). Consider before hemodialysis is initiated in patients treated with hydroxocobalamin.

SIDE EFFECTS

The most common side effects include chromaturia, decreased lymphocytes, erythema, headache, hypertension, injection site reactions, nausea, oxalate crystals in urine, and rash. Hypersensitivity reactions, hypertension, and renal injury are the most serious side effects associated with hydroxocobalamin. Other reactions that may occur include abdominal discomfort, chest discomfort, diarrhea, dizziness, dry throat, dyspepsia, dysphagia, dyspnea, hematochezia (blood in stool), hot flashes, impaired memory, irritation, peripheral edema, pruritus, redness and swelling of the eyes, restlessness, throat tightness, urticaria, and vomiting.

Post-Marketing:

Acute renal failure with acute tubular necrosis, renal impairment, and urine calcium oxalate crystals.

ANTIDOTE

Keep physician informed of all side effects; will be treated symptomatically. Note Compatibility before treating hypertension or seizures; use an alternate IV line if indicated. Severe hypersensitivity reactions may require epinephrine, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone), or bronchodilators (e.g., albuterol, theophylline). Data on overdose not available; manage symptomatically. Hemodialysis may be effective and is indicated for significant hydroxocobalamin toxicity. Cardiac and/or respiratory arrest may occur before treatment has an effect; resuscitate as indicated.

6% HYDROXYETHYL STARCH 130/0.4 IN 0.9% SODIUM CHLORIDE INJECTION BBW

(hy-**DROX**-ee-eth-ihl starch)
Voluven
Plasma volume substitute
pH 4 to 5.5

USUAL DOSE

Variable depending on patient's blood loss, maintenance or restoration of hemodynamics, and hemodilution (dilution effect). Daily dose may be administered repetitively over several days. Titrate to individual colloid needs, hydration status, and hemodynamics.

Initial infusion:

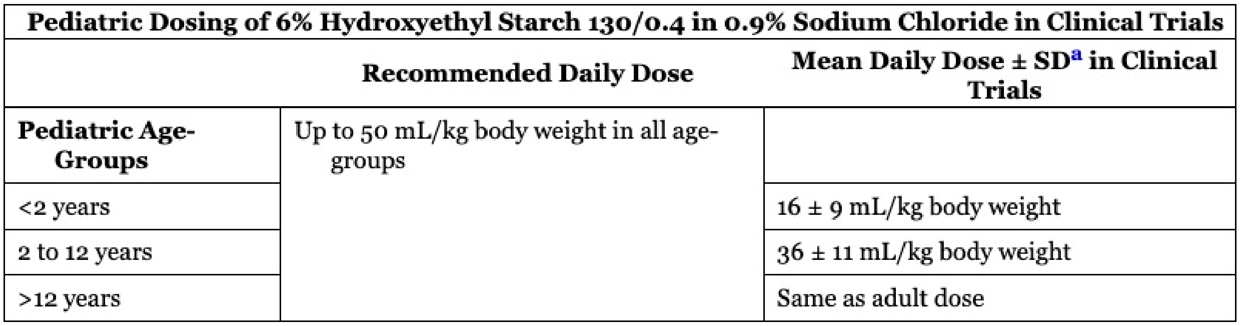
Administer initial 10 to 20 mL of infusion slowly. Observe patient continuously for S/S of a possible hypersensitivity reaction.

Daily dose:

Up to 50 mL/kg of body weight per day (equivalent to 3 Gm hydroxyethyl starch and 7.7 mEq sodium/kg body weight). This dose is equivalent to 3,500 mL for a 70-kg patient.

PEDIATRIC DOSE

See Usual Dose. Pediatric dose should be adjusted to the individual patient's colloid needs, taking into account the patient's underlying disease state and hemodynamic and hydration status. Doses used in clinical trials are listed in the following chart.



Pediatric Dosing of 6% Hydroxyethyl Starch 130/0.4 in 0.9% Sodium Chloride in Clinical Trials

	Recommended Daily Dose	**Mean Daily Dose ± SD[a] in Clinical Trials**
Pediatric Age-Groups	Up to 50 mL/kg body weight in all age-groups	
<2 years		16 ± 9 mL/kg body weight
2 to 12 years		36 ± 11 mL/kg body weight
>12 years		Same as adult dose

[a] *SD*, Standard deviation

DOSE ADJUSTMENTS

Use caution in patients with cardiac or renal dysfunction and in the elderly. Avoid fluid overload. Volume status, infusion rate, and urine output should be closely monitored. Lower-end initial dosing may be appropriate. Titrate to effect.

DILUTION

Available as a 6% solution in a ready-to-use 500-mL flexible plastic intravenous solution container. Remove overwrap immediately before administration. See manufacturer instructions for use of free/flex IV container. Administer through a nonvented standard infusion set. Air inlet of infusion set must be closed.

Storage:

Store at 15° to 25° C (59° to 77° F). Do not freeze. Use immediately after insertion of administration set. Manufacturer recommends changing administration set at least once every 24 hours. For single use only. Discard any unused portion.

COMPATIBILITY

Manufacturer states the safety and **compatibility** of additives have not been established.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Variable depending on indication, present blood volume, and patient response. Initial 10 to 20 mL should be infused slowly, keeping the patient under close observation because of possible anaphylactoid reactions. Do not hang flexible plastic containers in series connection, do not pressurize to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets. All may result in air embolism.

ACTIONS

A synthetic colloid for use in plasma volume expansion. Contains hydroxyethyl starch in a colloidal solution that expands plasma volume when administered intravenously. After isovolemic exchange of blood with 500 mL of Voluven in healthy volunteers, blood volume is maintained for at least 6 hours. Elimination half-life is 12 hours, and approximately 62% is excreted as hydroxyethyl starch molecules in urine within 72 hours.

INDICATIONS AND USES

Treatment and prophylaxis of hypovolemia in adults and pediatric patients. It is not a substitute for red blood cells or coagulation factors in plasma.

CONTRAINDICATIONS

Do not use in critically ill adult patients, including patients with sepsis. ■ Known hypersensitivity to hydroxyethyl starch. ■ Clinical conditions with fluid overload (e.g., pulmonary edema, congestive heart failure). ■ Renal failure with oliguria or anuria not related to hypovolemia. ■ Patients receiving dialysis. ■ Severe hypernatremia or severe hyperchloremia. ■ Intracranial bleeding. ■ Pre-existing coagulation or bleeding disorders. ■ Severe liver disease.

PRECAUTIONS

For IV use only. ■ Hypersensitivity reactions, including anaphylaxis, have been reported with solutions containing hydroxyethyl starch. ■ Use caution in patients with cardiac insufficiency. ■ In critically ill adult patients, including patients with sepsis, the use of hydroxyethyl starch (HES) products, including Voluven, increases the risk of mortality and renal replacement therapy. ■ Avoid use in patients with pre-existing renal dysfunction. ■ Discontinue at the first sign of renal injury. ■ Avoid fluid overload; see Dose Adjustments. ■ In cases of severe dehydration, a crystalloid solution should be administered first. In general, sufficient fluid should be administered to avoid dehydration. ■ At high dosages, the dilutional effects may result in decreased levels of coagulation factors and other plasma proteins and a decrease in hematocrit.

Monitor:

Monitor for S/S of hypersensitivity reactions (e.g., mild influenza-like symptoms, bradycardia, tachycardia, bronchospasm, hypotension, noncardiac pulmonary edema, anaphylaxis); see Rate of Administration. ■ Clinical evaluation and periodic laboratory determinations are necessary to monitor fluid balance, electrolyte concentrations, kidney function, acid-base balance, and coagulation parameters during prolonged parenteral therapy or whenever the patient’s condition warrants such evaluation. ■ Monitor coagulation status of patients undergoing open heart surgery with CABG. Excess bleeding has been reported. ■ Monitor BP, HR, and urine output. ■ Monitor fluid status and rate of administration closely, especially in patients with cardiac or renal insufficiency. ■ Continue to monitor renal function in hospitalized patients for at least 90 days because use of renal replacement therapy (RRT) has been reported up to 90 days after administration. ■ Monitor liver function and coagulation parameters. ■ Maintain adequate hydration of patient with additional IV fluids.

Maternal/Child:

Category C: benefit must justify potential risk to the fetus. Embryocidal to rabbits. ■ Information on use during labor and delivery unknown. Use only if clearly needed. ■ Use caution during breast-feeding. ■ See Pediatric Dose.

Elderly:

Differences in response between elderly and younger patients not identified, but greater sensitivity of some older individuals cannot be ruled out. Risk of adverse reactions may be greater in patients with impaired renal function. Monitoring of renal function suggested in the elderly.

DRUG/LAB INTERACTIONS

No interactions with other drugs or nutritional products are known. ■ Elevated serum amylase levels may be observed temporarily following administration. May interfere with diagnosis of pancreatitis. ■ Dilutional effects may result in decreased levels of coagulation factors and other plasma proteins and a decrease in hematocrit.

SIDE EFFECTS

The most common side effects include elevated serum amylase, hemodilution (resulting in a dilution of blood components [e.g., coagulation factors and other plasma proteins and a decrease in hematocrit]), and pruritus. Anaphylactoid/hypersensitivity reactions and disturbances in blood coagulation beyond dilution effects have occurred rarely. Increased mortality and need for renal replacement therapy in critically ill patients, including sepsis, were most serious.

Overdose:

May lead to overloading of circulatory system (e.g., pulmonary edema).

Post-Marketing:

Anaphylactic/anaphylactoid/hypersensitivity reactions and hypotension/shock/circulatory collapse, mortality, need for renal replacement therapy.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction and treat reaction as indicated. Antihistamines (diphenhydramine) and epinephrine may be indicated. Discontinue infusion immediately in the event of circulatory overload. A diuretic (furosemide) may be administered if necessary. Discontinue at the first sign of renal injury or coagulopathy. Treat side effects as indicated and resuscitate as necessary.

Trogarzo
Antiretroviral
Monoclonal antibody (Anti-CD4)
pH 6

USUAL DOSE

Loading dose:

2,000 mg as an IV infusion.

Maintenance dose:

800 mg as an IV infusion every 2 weeks following the initial loading dose. If a maintenance dose (800 mg) is missed by 3 days or longer beyond the scheduled dosing day, a loading dose (2,000 mg) should be administered as early as possible. Resume maintenance dosing (800 mg) every 14 days thereafter.

DOSE ADJUSTMENTS

No dose modifications required when administered with any other antiretroviral or any other treatments. ■ No formal studies conducted to examine the effects of renal or hepatic impairment on the pharmacokinetics of ibalizumab-uiyk. Renal impairment is not anticipated to affect the pharmacokinetics of ibalizumab-uiyk.

DILUTION

Available in a single-dose vial containing 200 mg/1.33 mL (150 mg/mL). Solution is colorless to slightly yellow and clear to slightly opalescent. Ten vials (13.3 mL) are required for the loading dose. Four vials are required for the maintenance dose (5.32 mL). Withdraw 1.33 mL of solution from each vial and transfer into a 250 mL IV bag of NS. Once diluted, the solution should be administered immediately.

Filters:

Specific information not available.

Storage:

Before use, refrigerate vials at 2° to 8° C (36° to 46° F) in original cartons to protect from light. Do not freeze. Once diluted, the ibalizumab-uiyk solution should be administered immediately. If not administered immediately, store diluted solution at RT (20° to 25° C [68° to 77° F]) for up to 4 hours, or refrigerate (2° to 8° C [36° to 46° F]) for up to 24 hours. If refrigerated, allow the diluted solution to stand at RT for at least 30 minutes but no more than 4 hours before administration. Discard partially used or empty vials and any unused portion of the diluted solution.

COMPATIBILITY

Compatible only with NS. Manufacturer states, “Other IV diluents must not be used to prepare ibalizumab-uiyk solution for infusion.”

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. Manufacturer suggests administration into the cephalic vein of the patient’s right or left arm. If cephalic vein is not accessible, an appropriate vein located elsewhere can be used.

Loading dose:

The duration of the first infusion (loading dose) should be no less than 30 minutes.

Maintenance dose:

If no infusion reactions have occurred with the loading dose, the duration of the subsequent infusions ***(maintenance doses)*** can be decreased to no less than 15 minutes. After infusion is complete, flush with 30 mL NS.

ACTIONS

Ibalizumab-uiyk is a CD4-directed postattachment HIV-1 inhibitor. It is a recombinant humanized monoclonal antibody that blocks HIV-1 from infecting $CD4^+$ T-cells by binding to domain 2 of CD4 and interfering with the postattachment steps required for the entry of HIV-1 virus particles into host cells and preventing the viral transmission that occurs via cell-cell fusion. The binding specificity of ibalizumab-uiyk to domain 2 of CD4 allows ibalizumab-uiyk to block viral entry into host cells without causing immunosuppression.

INDICATIONS AND USES

Given in combination with other antiretroviral(s) for the treatment of human immunodeficiency virus type 1 (HIV-1) infection in heavily treatment-experienced adults with multidrug-resistant HIV-1 infection who are failing their current antiretroviral regimen.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Immune reconstitution inflammatory syndrome has been reported. During the initial phase of combination antiretroviral therapies, patients whose immune systems respond may develop an inflammatory response to indolent or residual opportunistic infections, which may require further evaluation and treatment. ■ Infusion-associated reactions may occur. ■ As with all therapeutic proteins, there is potential for immunogenicity.

Monitor:

Monitor during and for 1 hour after completion of ibalizumab-uiyk administration for at least the first infusion. If no infusion-associated adverse reaction is observed, the postinfusion observation time may be reduced to 15 minutes. ■ Monitor patient for any new symptoms after receiving ibalizumab-uiyk.

Patient Education:

Read the FDA-approved patient information. ■ Review all medicines being taken, including prescription and nonprescription medications, with health care provider. ■ Immediately report any S/S of infection. ■ It is important to receive ibalizumab-uiyk injections every 2 weeks and not to change the dosing schedule or any antiretroviral medication without consulting with health care provider. Immediately contact health care provider if ibalizumab-uiyk or any other drug in antiretroviral regimen is stopped.

Maternal/Child:

No adequate human data are available to establish whether ibalizumab-uiyk poses a risk to pregnancy outcomes. ■ A pregnancy exposure registry has been established; contact manufacturer. ■ Women infected with HIV should be instructed not to breast-feed due to the potential for HIV transmission to the infant. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No studies have been conducted in elderly patients.

DRUG/LAB INTERACTIONS

No drug interaction studies have been conducted. Based on ibalizumab-uiyk’s mechanism of action and target-mediated drug disposition, drug-drug interactions are not expected.

SIDE EFFECTS

The most common side effects were diarrhea, dizziness, nausea, and rash. Severe rash occurred in one patient, and immune reconstitution inflammatory syndrome (manifested as an exacerbation of progressive multifocal leukoencephalopathy) occurred in another. Laboratory abnormalities include elevated bilirubin, direct bilirubin, creatinine, blood glucose, lipase, and uric acid, and decreased hemoglobin, platelets, leukocytes, and neutrophils.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Treat infusion reactions as appropriate based on severity.

IBANDRONATE SODIUM

(i-**BAN**-dro-nate **SO**-dee-um)
Boniva
Bone resorption inhibitor
Bisphosphonate

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Ibandronate:

3 mg as an IV injection over 15 to 30 seconds every 3 months. Supplemental calcium and vitamin D may be required. See Precautions. Do not administer more frequently than every 3 months; if a dose is missed, administer it as soon as it can be rescheduled, and schedule the next injection for 3 months from that date.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, or impaired hepatic function. ■ No dose adjustment is indicated for impaired kidney function in patients with a CrCl equal to or greater than 30 mL/min; see Contraindications.

DILUTION

May be given undiluted. Available in a prefilled syringe with a 25-gauge needle and a needle-stick protection device. Administer only with the provided 25-gauge needle.

Storage:

Store at CRT. Syringes are for single use only; discard unused drug.

COMPATIBILITY

Manufacturer states, “Must not be mixed with calcium-containing solutions or other intravenously administered drugs.”

RATE OF ADMINISTRATION

A single dose as an IV injection over 15 to 30 seconds.

ACTIONS

A nitrogen-containing bisphosphonate. Action is based on its affinity for hydroxyapatite, which is part of the mineral matrix of bone. Ibandronate inhibits osteoclast activity and reduces bone resorption and turnover. In postmenopausal women with osteoporosis, it increases bone mineral density and reduces the incidence of vertebral fractures. Either rapidly binds to bone (40% to 50% of a dose) or is excreted unchanged in urine (50% to 60%). No evidence that it is metabolized in humans. Eliminated unchanged by the kidneys. Terminal half-life is dose dependent and ranged from 4.6 to 25.5 hours in studies in which 2 and 4 mg of ibandronate were administered. Renal clearance is related to CrCl. Patients with a CrCl less than 30 mL/min have a more than twofold increase in exposure (AUC) than do patients with a CrCl greater than 80 mL/min.

INDICATIONS AND USES

Treatment of osteoporosis in postmenopausal women.

Limitation of use:

Safety and effectiveness based on clinical data of 1-year duration; optimal duration of use has not been determined. Re-evaluate on a periodic basis. Consider discontinuing ibandronate after 3 to 5 years of use in patients at low risk for fracture, and re-evaluate risk for fracture periodically in patients who discontinue ibandronate.

CONTRAINDICATIONS

Hypersensitivity to ibandronate or its excipients, uncorrected hypocalcemia, severe impaired renal function (CrCl less than 30 mL/min).

PRECAUTIONS

For IV injection only. Confirm patency of vein. Intra-arterial or paravenous administration could lead to tissue damage. ■ Anaphylaxis, including fatal events, has been reported. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ Disturbances of bone and mineral metabolism (e.g., hypocalcemia, hypovitaminosis D) must be treated before administration of ibandronate. ■ Bisphosphonates have been associated with a deterioration in renal function (e.g., increased SCr, acute renal failure [rare]). Use caution in patients who have concomitant diseases or are taking concomitant medications that may have adverse effects on the kidneys. ■ Osteonecrosis of the jaw (ONJ) has been reported in patients receiving bisphosphonates. The majority of cases have been in cancer patients undergoing dental procedures. However, some cases have been reported in patients with postmenopausal osteoporosis treated with either oral or IV bisphosphonates. Risk factors include cancer, concomitant therapy (e.g., chemotherapy, angiogenesis inhibitors, radiotherapy, corticosteroids), and comorbid conditions (e.g., anemia, coagulopathies, infection, pre-existing oral disease). Risk may increase with duration of exposure to bisphosphonates. Consider dental exam and appropriate preventive dentistry before beginning therapy with bisphosphonates. Avoid invasive dental procedures during bisphosphonate therapy. Dental surgery may exacerbate ONJ in patients who develop ONJ while on bisphosphonate therapy. ■ Severe and occasionally incapacitating bone, joint, and muscle pain has been reported rarely. Symptoms may occur from one day to several months after initiation of treatment. In most cases, pain resolves when ibandronate is discontinued. A subset of patients had recurrence of symptoms when rechallenged with the same drug or another bisphosphonate. ■ Atypical, low-energy, or low-trauma fractures of the femoral shaft have been reported in bisphosphonate-treated patients. May be bilateral. Many patients report prodromal pain in the affected area, which usually presents as dull, aching thigh pain weeks to months before a complete fracture occurs. Patients presenting with thigh or groin pain should be evaluated to rule out an incomplete femur fracture. Patients presenting with an atypical fracture should also be assessed for S/S of fracture in the contralateral limb.

Monitor:

Obtain baseline measurements of serum calcium, magnesium, phosphate, and serum creatinine; see Precautions. ■ Perform a routine oral examination with appropriate preventive dentistry before administration. ■ May cause a transient decrease in serum calcium values. ■ Daily supplements of calcium and vitamin D may be required during therapy with ibandronate if dietary intake is inadequate. ■ Monitor SCr before each dose. Nephropathy has been reported; see Precautions. Withhold treatment for renal deterioration. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Influenza-like side effects (e.g., bone, muscle, or joint pains; chills; fever; fatigue) consistent with an acute-phase reaction have been reported. Incidence is higher with IV administration. Usually occurs within 3 days of injection and lasts 7 days or fewer. In most cases, symptoms generally subside within 24 to 48 hours, and treatment other than acetaminophen has not been required.

Patient Education:

Read manufacturer's patient information sheet before each infusion. ■ Daily supplements of calcium and vitamin D may be required during therapy with ibandronate. ■ Discuss your health history (e.g., kidney problems, diabetes, high blood pressure, heart disease, planned tooth extraction) and prescription and nonprescription medications with health care providers, including your dentist. ■ Promptly report persistent pain and/or nonhealing sores of the mouth or jaw. ■ Promptly report chills and/or fever and other S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath). ■ Report development of bone, joint, or muscle pain promptly. Onset of pain is variable. ■ Promptly report thigh or groin pain. ■ Do not administer more frequently than every 3 months; if a dose is missed, administer it as soon as it can be rescheduled, and schedule the next injection for 3 months from that date. ■ Laboratory monitoring of renal function required before each dose. ■ Flu-like symptoms may occur within the first 3 days of therapy and usually resolve within 24 to 48 hours. Administration of acetaminophen may reduce incidence of symptoms.

Maternal/Child:

Ibandronate is not indicated for use in women of reproductive potential. There are no data regarding use during pregnancy or with breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to that seen in younger patients; however, greater sensitivity cannot be ruled out. ■ Monitor renal function. Consider impaired renal function and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

Does not inhibit cytochrome P_{450} isoenzymes. ■ Bisphosphonates are known to interfere with the use of **bone-imaging agents;** ibandronate has not been studied.

SIDE EFFECTS

Abdominal pain, arthralgia, and back pain are the most common side effects. Other commonly reported side effects include headache, increased SCr, influenza-like illness (bone, muscle, or joint pains; chills; fever; fatigue), and injection site reactions (redness or swelling). Less frequent side effects include bronchitis, constipation, cystitis, depression, diarrhea, dizziness, dyspepsia, extremity pain, gastritis, gastroenteritis, hypertension, hypocalcemia, insomnia, localized osteoarthritis, myalgia, nasopharyngitis, nausea, rash, upper respiratory infection, urinary tract infection.

Overdose:

Hypocalcemia, hypomagnesemia, and hypophosphatemia.

Post-Marketing:

Acute renal failure; atypical, low-energy, or low-trauma fractures of the femoral shaft; eye inflammation (iritis and uveitis); hypersensitivity reactions, including anaphylaxis (with fatalities), angioedema, asthma exacerbation, bronchospasm, dermatitis bullous, erythema multiforme, rash, and Stevens-Johnson syndrome; osteonecrosis of the jaw and other orofacial sites, including the external auditory canal; severe or incapacitating musculoskeletal pain.

ANTIDOTE

Keep physician informed of side effects. Most will respond to symptomatic treatment. Withhold treatment for renal deterioration. Treat clinically relevant reductions in serum levels of calcium, magnesium, and phosphorus with IV administration of calcium gluconate, magnesium sulfate, and/or potassium or sodium phosphate as indicated. Discontinue ibandronate if severe bone, joint, or muscle pain develops. To be beneficial, dialysis must be administered within 2 hours of overdose. Treat anaphylaxis and/or resuscitate as indicated.

IBUPROFEN BBW

(**EYE**-bue-**PROE**-fen)
Caldolor
NSAID
pH 7.4

USUAL DOSE

Pretreatment:

Baseline assessment and studies indicated; see Monitor. See Maternal/Child.

Use the lowest effective dose for the shortest duration of time based on individual needs and response. Re-evaluate after the initial dose. Adjust dose and frequency as indicated. Total daily dose should not exceed 3,200 mg. Adequate hydration and correction of hypovolemia required before administration to reduce the risk of adverse renal reactions.

Analgesia:

400 to 800 mg every 6 hours as necessary.

Antipyretic:

400 mg followed by 400 mg every 4 to 6 hours or 100 to 200 mg every 4 hours as necessary.

PEDIATRIC DOSE

Pediatric Dosing of Ibuprofen for Fever and Pain

Age-Group	Dose	Dosing Interval	Maximum Daily Dose[a]
6 months to less than 12 years	10 mg/kg up to 400 mg max	Every 4 to 6 hr as needed	40 mg/kg or 2,400 mg
12 to 17 years	400 mg	Every 4 to 6 hr as needed	2,400 mg

[a] Maximum daily dose is 40 mg/kg or 2,400 mg, whichever is less.

See comments under Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

To minimize the potential risk for an adverse cardiovascular (CV) event, use the lowest effective dose for the shortest duration possible. ■ Lower-end initial and reduced doses may be indicated in the elderly and/or debilitated. Consider potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available as an 800 mg/200 mL (4 mg/mL) single-dose, ready-to-use flexible bag or as an 800 mg/8 mL single-dose vial (100 mg/mL). Vial must be diluted to a final concentration of 4 mg/mL or less for both adult and weight-based pediatric dosing using NS, D5W, or LR. Infusion without dilution can cause hemolysis. The 800 mg/200 mL ready-to-use bag is intended for 800-mg doses only.

Filters:

Specific information not available; consult pharmacist.

Storage:

Store vials at CRT. Diluted solutions stable for up to 24 hours at 20° to 25° C (68° to 77° F) and with ambient room lighting.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adult:

A single dose as an infusion over no less than 30 minutes.

Pediatric:

A single dose as an infusion over no less than 10 minutes.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID) that has anti-inflammatory, analgesic, and antipyretic activity. Mechanism of action is not completely understood but involves inhibition of cyclooxygenase (COX-1 and COX-2). It inhibits synthesis of prostaglandins, which are potent mediators of inflammation. Highly protein bound; the mean half-life of a 400-mg dose is 2.2 hours, and the mean half-life of an 800-mg dose is 2.44 hours. Metabolized in the liver via oxidation and excreted in the urine.

INDICATIONS AND USES

Management of mild to moderate pain. ■ Management of moderate to severe pain as an adjunct to opioid analgesics. ■ Reduction of fever.

CONTRAINDICATIONS

Known hypersensitivity (anaphylactoid reactions, serious skin reactions) to ibuprofen or any component of the product. ■ Known history of asthma, urticaria, or allergic-type reactions after taking aspirin or other NSAIDs. ■ In the setting of coronary artery bypass graft (CABG) surgery. ■ See Maternal/Child.

PRECAUTIONS

For IV infusion only. ■ NSAIDs increase the risk for serious cardiovascular (CV) thrombotic events, including MI and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. The increase in CV thrombotic risk has been observed most consistently at higher doses. ■ There is no consistent evidence that concurrent use of aspirin mitigates the increased risk of serious CV thrombotic events associated with NSAID therapy. However, concurrent use does increase the risk of serious GI toxicity. ■ An increased incidence of MI and stroke was seen in patients who received a NSAID as an analgesic after CABG surgery; see Contraindications. ■ Avoid the use of ibuprofen in patients with a recent MI or in patients with severe heart failure unless the benefits are expected to outweigh the risks. Studies have shown these patients to be at increased risk for reinfarction, CV-related death, and all-cause mortality. ■ NSAIDs increase the risk for serious GI adverse events, including ulceration, bleeding, and/or perforation of the stomach or intestines. Can occur at any time, with or without warning symptoms, and can be fatal. Use extreme caution in patients with a prior history of peptic ulcer disease or GI bleeding. Risk is also increased in elderly or debilitated patients, in patients with advanced liver disease, and with concomitant use of aspirin, oral corticosteroids, anticoagulants, alcohol, selective serotonin reuptake inhibitors (SSRIs), or smoking or with longer durations of therapy. ■ May cause elevations of liver function tests (e.g., ALT, AST). Rare cases of serious, sometimes fatal, hepatic injury (fulminant hepatitis, liver necrosis, hepatic failure) have occurred. ■ May cause fluid retention and edema; use caution in patients with CHF or edema; see Drug/Lab Interactions. ■ May precipitate new-onset hypertension or worsen pre-existing hypertension; see Drug/Lab Interactions. ■ In addition to the usual caution in patients with reduced hepatic or renal function, NSAIDs may cause a dose-dependent reduction in renal prostaglandin formation and, secondarily, in renal blood flow, which can precipitate renal failure. Patients with impaired renal function, heart failure, liver dysfunction, dehydration, or hypovolemia; elderly patients; and patients receiving ACE inhibitors, angiotensin receptor blockers (ARBs), or diuretics are at greatest risk. ■ Avoid ibuprofen use in patients with advanced renal disease unless the benefits are expected to outweigh the risk. ■ Increases in serum potassium, including hyperkalemia, have been reported. ■ Anaphylactic reactions have occurred in patients with and without known hypersensitivity to ibuprofen and in patients with aspirin-sensitive asthma. Cross-reactivity between aspirin and other NSAIDs has been reported in aspirin-sensitive patients; see Contraindications. Use caution in patients with pre-existing asthma (without known aspirin sensitivity), and monitor for changes in S/S of asthma. ■ May cause serious skin reactions (e.g., exfoliative dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis) without warning; some have been fatal. ■ Anti-inflammatory and antipyretic effects may reduce the utility of these diagnostic signs in detecting infections. ■ May cause anemia. Anemia may be due to occult or gross GI blood loss, fluid retention, or an incompletely described effect on erythropoiesis. ■ NSAIDs inhibit platelet aggregation and may increase the risk of bleeding. Risk may be increased with comorbid conditions such as coagulation disorders or with concomitant use of several medications; see Drug/Lab Interactions. ■ Aseptic meningitis and ophthalmologic effects (e.g., blurred or diminished vision, changes in color vision) have been reported with oral ibuprofen. ■ See Maternal/Child.

Monitor:

Correct hypovolemia before administration and maintain adequate hydration. ■ Obtain baseline blood pressure and monitor frequently during therapy. ■ Consider baseline CBC, electrolytes, liver function tests, and SCr or CrCl. Repeat as needed if S/S of toxicity/adverse events develop. ■ Monitor patients with or without a previous history of CV disease for S/S of CV events (e.g., chest pain, dyspnea, edema, hypertension, limb or facial paralysis). ■ Monitor for edema or signs of worsening heart failure. ■ Observe for S/S of GI ulceration or bleeding and/or liver dysfunction. ■ Monitor renal function, especially in patients with impaired renal function. ■ Monitor for S/S of hypersensitivity or serious skin reactions (e.g., anaphylaxis, pruritus, rash, urticaria, or wheezing). ■ Monitor patients who may be adversely affected by alterations in platelet function (e.g., patients with coagulation disorders or patients receiving anticoagulants) for signs of bleeding.

Patient Education:

Review FDA-approved medication guide. ■ Side effects have resulted in extended hospitalization and could be fatal. ■ Promptly report any S/S of CV thrombotic events (e.g., chest pain, shortness of breath, slurred speech, weakness), GI adverse events (e.g., dyspepsia, epigastric pain, hematemesis, melena), hepatotoxicity (e.g., diarrhea, fatigue, flu-like symptoms, jaundice, lethargy, nausea, pruritus, right upper quadrant tenderness), heart failure (e.g., edema, shortness of breath, weight gain), serious skin reaction, and/or a hypersensitivity reaction (e.g., difficulty breathing, swelling of the face or throat) or any type or rash. ■ Avoid use of concomitant NSAIDs. Over-the-counter medications for the treatment of fever, cold, and insomnia may contain NSAIDs. Consult pharmacist before use. ■ Discuss use of low-dose aspirin for cardiac prophylaxis with health care provider before initiating concomitant therapy; may increase risk of GI toxicity. ■ May be associated with a reversible delay in ovulation. ■ See Maternal/Child.

Maternal/Child:

Avoid use starting at 30 weeks' gestation (third trimester); premature closure of the ductus arteriosus in the fetus may occur. Use before 30 weeks' gestation only if the potential benefit justifies the potential risk to the fetus. ■ Effects during labor and delivery unknown. ■ Use with caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 6 months of age not established.

Elderly:

Increased risk for serious NSAID-associated GI, cardiovascular, and/or renal adverse events. ■ Dosing should be cautious; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Concurrent use with other **NSAIDs, aspirin,** or other **salicylates** is not recommended; may increase the risk of toxicity and serious GI events. ■ Ibuprofen may interfere with the platelet affect in patients taking low-dose aspirin for cardioprotection, increasing the risk of CV events. In these patients, consider use of an alternate analgesic that does not interfere with the antiplatelet effect of aspirin. ■ Increased risk of bleeding with concomitant use of **anticoagulants, antiplatelet agents, SSRIs**, and **serotonin-norepinephrine reuptake inhibitors (SNRIs)**. Monitor patients closely if concomitant use indicated. ■ NSAIDs may decrease the effectiveness of **ACE inhibitors, angiotensin receptor blockers (ARBs)**, and **beta-blockers**; monitor BP. ■ Coadministration with an **ACE inhibitor** or **ARB** may result in deterioration of renal function in at-risk patients; monitor renal function. ■ Ibuprofen can reduce the natriuretic effects of **loop diuretics** (e.g., furosemide) and **thiazide diuretics** (e.g., hydrochlorothiazide); observe for signs of worsening renal function and ensure diuretic/therapeutic effectiveness. ■ May increase **digoxin** serum concentration and prolong half-life of digoxin; monitor digoxin levels with concomitant use. ■ Concurrent use of **lithium** with NSAIDs may decrease lithium clearance, increasing plasma levels of lithium; observe for signs of lithium toxicity. ■ Concurrent use of NSAIDs with **methotrexate** may enhance methotrexate toxicity (e.g., neutropenia, thrombocytopenia, renal dysfunction); monitor for signs of methotrexate toxicity. ■ Concomitant use with **cyclosporine** may increase cyclosporine's nephrotoxicity; monitor renal function. ■ Concomitant use with **pemetrexed** may increase the risk of pemetrexed-associated myelosuppression and renal and GI toxicity; avoid concomitant use for 2 to 5 days before pemetrexed administration and for 2 days following administration in patients with mild to moderate renal impairment (CrCl 45 to 79 mL/min). See pemetrexed monograph.

SIDE EFFECTS

Adults:

The most common side effects are dizziness, flatulence, headache, hemorrhage, and nausea and vomiting. Other side effects include abdominal discomfort, anemia, bacteremia, bacterial pneumonia, cough, diarrhea, dyspepsia, eosinophilia, hyperkalemia, hypernatremia, hypertension, hypoalbuminemia, hypokalemia, hypoproteinemia, hypotension, increased blood urea, increased lactic dehydrogenase (LDH), neutropenia, peripheral edema, thrombocytosis, urinary retention, wound hemorrhage. See Precautions for potential major side effects.

Pediatric patients:

The most common side effects are anemia, headache, infusion site pain, nausea, and vomiting.

Overdose:

Acute renal failure, coma, drowsiness, epigastric pain, GI bleeding, hypertension, lethargy, nausea, respiratory depression, and vomiting.

ANTIDOTE

Keep the physician informed of significant side effects. With increasing severity or onset of symptoms of any major side effect (e.g., CHF; edema; hypersensitivity reactions; GI bleeding, ulceration, or perforation; hepatic or renal effects; hypertension; skin reactions; thrombotic events), discontinue the drug and notify the physician. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly if indicated. Treat anaphylaxis with epinephrine, diphenhydramine, and corticosteroids as indicated. No known antidote. Forced diuresis, alkalinization of urine, hemodialysis, or hemoperfusion may not be useful due to high protein binding.

IBUPROFEN LYSINE

(eye-byou-**PROH**-fen **LIE**-seen)
NeoProfen
NSAID (patent ductus arteriosus adjunct)
pH 7

NEONATAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

All doses are based on birth weight. A course of therapy is three doses given at 24-hour intervals.

Initial dose:

10 mg/kg. Follow with a dose of 5 mg/kg in 24 hours and repeat at 48 hours; see Dose Adjustments.

After completion of the first course, no further doses are indicated if the ductus arteriosus closes or is significantly reduced in size. If the ductus arteriosus fails to close or reopens, a second course, alternative pharmacologic therapy, or surgery may be necessary.

DOSE ADJUSTMENTS

If urine output is less than 0.6 mL/kg/hr at any time a dose is to be given, withhold dose until lab studies confirm a return to normal renal function.

DILUTION

Each single dose must be diluted to an appropriate volume for administration as an infusion over 15 minutes with dextrose or saline. Prepare for infusion and begin administration within 30 minutes of preparation. A fresh solution should be prepared just before each administration. Contains no preservatives; discard any unused portion.

Filters:

Specific information not available.

Storage:

Store vials in cartons at CRT and protect from light until use. Use reconstituted solution within 30 minutes of preparation.

COMPATIBILITY

Manufacturer states, “Should not be simultaneously administered in the same IV line with Total Parenteral Nutrition” (TPN). If required, interrupt TPN for 15 minutes before and after ibuprofen administration. Maintain IV line patency with dextrose or saline infusion.

RATE OF ADMINISTRATION

Administer via the IV port nearest the insertion site.
A single dose, properly diluted, and infused continuously over 15 minutes.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID). Mechanism of action by which it causes closure of a patent ductus arteriosus (PDA) is unknown; however, in adults it is an inhibitor of prostaglandin synthesis. By closing the patent ductus arteriosus, the need for surgical intervention is eliminated. Half-life varies inversely with postnatal age, but in general the half-life in infants is more than 10 times longer than in adults. In lower-birth-weight premature infants, half-life may range from 20 to 51 hours. Metabolism and excretion have not been studied in premature infants. In adults, it is metabolized in the liver and excreted in the urine and feces.

INDICATIONS AND USES

Closure of a clinically significant patent ductus arteriosus in premature infants weighing between 500 and 1,500 Gm who are no more than 32 weeks' gestational age when usual medical management (e.g., fluid restriction, diuretics, respiratory support) is not effective. Consequences beyond 8 weeks after treatment have not been evaluated.

CONTRAINDICATIONS

Preterm infants with proven or suspected infection that is untreated. ■ Preterm infants with congenital heart disease in whom patency of the PDA is necessary for satisfactory pulmonary or systemic blood flow (e.g., pulmonary atresia, severe tetralogy of Fallot, severe coarctation of the aorta). ■ Preterm infants who are bleeding, especially those with active intracranial hemorrhage or gastrointestinal bleeding. ■ Preterm infants with thrombocytopenia. ■ Preterm infants with coagulation defects. ■ Preterm infants with or who are suspected of having necrotizing enterocolitis. ■ Preterm infants with significant impairment of renal function.

PRECAUTIONS

For IV use only; see Monitor. ■ Reserve for infants with clear evidence of a clinically significant PDA. ■ For use only in a highly supervised setting such as an intensive care nursery. ■ No long-term evaluations available. Effects of ibuprofen on neurodevelopmental outcome and growth and on disease processes associated with prematurity (e.g., retinopathy of prematurity, chronic lung disease) have not been assessed. ■ May alter the usual signs of infection. Use with extreme caution in the presence of an existing controlled infection and in infants at risk for infection. ■ Can inhibit platelet aggregation. ■ Can prolong bleeding time in adults; use caution in infants with underlying hemostatic defects; see Contraindications. ■ Can displace bilirubin from albumin-binding sites; use with caution in infants with elevated total bilirubin.

Monitor:

Confirm absolute patency of vein. Avoid extravasation; will irritate tissue. Administration via an umbilical arterial line has not been studied. ■ Obtain baseline and monitor vital signs, oxygenation, acid-base status, fluid and electrolyte balance, and kidney function (SCr, BUN, urine output). ■ Can cause a reduction in urine output, increased BUN and SCr, and a decreased CrCl; may progress to oliguria or renal failure. Monitor all infants closely, especially those with some degree of renal impairment. ■ May inhibit platelet aggregation; monitor for signs of bleeding. ■ Monitor for signs of infection. ■ See Drug/Lab Interactions.

Maternal/Child:

Safety and effectiveness have been established only for use in premature infants.

DRUG/LAB INTERACTIONS

Ibuprofen may reduce the effects of **diuretics**; diuretics can increase the risk of nephrotoxicity of **NSAIDs** in dehydrated patients. Monitor renal function in patients receiving concomitant diuretics. ■ Ibuprofen may decrease the clearance of **amikacin**.

SIDE EFFECTS

The most commonly reported side effects include adrenal insufficiency, anemia, apnea, atelectasis, decreased urine output, edema, GI disorders (including nonnecrotizing enterocolitis), hematuria, hypernatremia, hypocalcemia, hypoglycemia, increased BUN and SCr, intraventricular hemorrhage and other bleeding, renal failure, renal insufficiency, respiratory failure, respiratory infection, sepsis, skin lesion or irritation, and urinary tract infection. Other side effects of unknown association include abdominal distension, cardiac failure, cholestasis, convulsions, feeding problems, gastritis, gastroesophageal reflux, hypotension, ileus, infections, inguinal hernia, injection site reactions, jaundice, lab abnormalities (e.g., hyperglycemia, neutropenia, thrombocytopenia), and tachycardia.

Post-Marketing:

GI perforation, necrotizing enterocolitis, and pulmonary hypertension.

Overdose:

Breathing difficulties, coma, drowsiness, hypotension, irregular heartbeat, kidney failure, seizures, and vomiting have occurred in individuals (not necessarily in premature infants) following overdose of oral ibuprofen.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Based on severity, side effects may be treated symptomatically or drug will be completely discontinued in favor of surgical intervention. In case of overdose, there is no specific antidote. Treat symptomatically and follow for several days after apparent recovery; GI ulceration and hemorrhage may occur. Resuscitate as necessary.

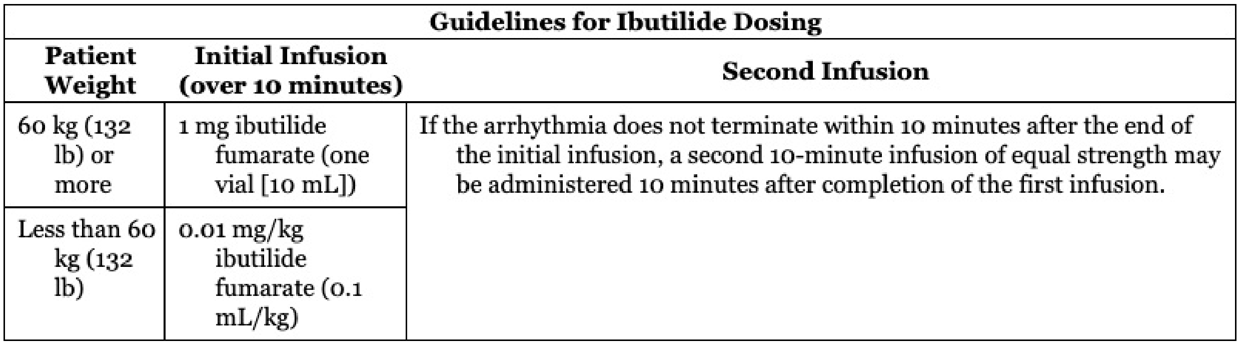
IBUTILIDE FUMARATE BBW

(ih-**BYOU**-tih-lyd **FU**-mar-ayt)
Corvert
Antiarrhythmic
pH 4.6

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.



Guidelines for Ibutilide Dosing		
Patient Weight	**Initial Infusion (over 10 minutes)**	**Second Infusion**
60 kg (132 lb) or more	1 mg ibutilide fumarate (one vial [10 mL])	If the arrhythmia does not terminate within 10 minutes after the end of the initial infusion, a second 10-minute infusion of equal strength may be administered 10 minutes after completion of the first infusion.
Less than 60 kg (132 lb)	0.01 mg/kg ibutilide fumarate (0.1 mL/kg)	

Discontinue infusion promptly when the presenting arrhythmia is terminated (desired effect). Must also be discontinued immediately if sustained or nonsustained ventricular tachycardia or marked prolongation of QT or QTc occurs (adverse effects). Postconversion treatment with appropriate antiarrhythmics (e.g., digoxin, verapamil, or propranolol) is usually required.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy. ■ No adjustments required in patients with impaired hepatic or renal function; see Monitor. Lower doses may be indicated in post–cardiac surgery patients. In recent studies one or two infusions of 0.5 mg in patients weighing 60 kg or more or 0.005 mg/kg/dose for patients under 60 kg was effective in terminating atrial fibrillation and/or flutter.

DILUTION

May be given undiluted or may be diluted in 50 mL of NS or D5W and given as an infusion. 1 mg (10 mL of a 0.1-mg/mL solution) of ibutilide in 50 mL diluent yields 0.017 mg/mL.

Storage:

Store at CRT in carton until use. Stable after dilution for 24 hours at room temperature, 48 hours if refrigerated.

COMPATIBILITY

Manufacturer lists as **compatible** with NS and D5W packaged in glass, polyvinyl chloride, or polyolefin infusion containers. Additional information not available; consult pharmacist.

RATE OF ADMINISTRATION

A single dose by injection or infusion over 10 minutes.

ACTIONS

A Class III antiarrhythmic agent that produces mild slowing of the sinus rate and atrioventricular conduction. Delays repolarization by activation of a slow inward current (sodium) rather than blocking outward potassium currents. Prolonged atrial and ventricular action potential duration and refractoriness result. Produces dose-related prolongation of the QT interval (may result from dose of ibutilide or rate of injection). Conversion of atrial flutter/fibrillation usually occurs within 30 minutes but may take up to 90 minutes after the start of the infusion. Most patients remain in normal sinus rhythm (NSR) for 24 hours. At recommended doses, ibutilide has no clinically significant effects on cardiac output, mean pulmonary arterial pressure, or pulmonary capillary wedge pressure. Rapidly distributed and metabolized. Elimination half-life is 6 hours (range 2 to 12 hours). Primarily excreted in urine (7% as unchanged drug). Excreted in small amounts in feces.

INDICATIONS AND USES

Rapid conversion of recent-onset atrial fibrillation or atrial flutter to sinus rhythm. Patients with more recent onset of arrhythmia have a higher rate of conversion. Effectiveness was less in those with a longer-duration arrhythmia.

CONTRAINDICATIONS

Known hypersensitivity to ibutilide or any of its components. ■ Not recommended in patients who have had a previous polymorphic ventricular tachycardia (e.g., torsades de pointes). ■ See Drug/Lab Interactions.

PRECAUTIONS

For IV infusion only. ■ Usually administered by or under the direction of the physician specialist. ■ Skilled personnel and proper equipment (e.g., cardiac monitors, intracardiac pacing facilities, cardioverter/defibrillator, emergency drugs) must be immediately available. ■ May cause life-threatening arrhythmias (e.g., torsades de pointes) with or without documented QT prolongation. ■ Correct hypokalemia and hypomagnesemia before use; may exaggerate a prolonged QT and cause arrhythmias. ■ Adequate anticoagulation (usually at least 2 weeks) is required for any patient with atrial fibrillation of more than 2 to 3 days' duration. ■ Select patients carefully; benefits (potential for maintaining sinus rhythm) must outweigh risks. Patients with chronic atrial fibrillation are more likely to revert back to atrial fibrillation after conversion to sinus rhythm. Patients with a QTc interval greater than 440 msec or a serum potassium less than 4.0 mEq/L are at very high risk to develop life-threatening arrhythmias. ■ Patients with a history of CHF may be more susceptible to sustained polymorphic VT. ■ Slightly more effective in atrial flutter than atrial fibrillation. ■ See Drug/Lab Interactions.

Monitor:

Obtain weight, baseline vital signs, and ECG before administration. Continuous ECG monitoring during and after infusion indicated to observe for arrhythmias. Watch for QT or QTc prolongation; may cause arrhythmia (torsades de pointes) with or without QT prolongation. ■ Monitor BP and HR. Bradycardia, a varying HR, and/or hypokalemia may increase risk of arrhythmia. ■ Arrhythmia occurs most frequently within 40 minutes of completion of infusion but may occur for up to 3 hours after infusion. Monitor ECG for a minimum of 4 hours or until QTc has returned to baseline. Monitor longer if there are any episodes of arrhythmias or if the patient has impaired liver function.

Patient Education:

Report promptly any feeling of faintness, difficulty breathing, or pain or stinging along injection site.

Maternal/Child:

Category C: benefits must outweigh risks. Caused birth defects and was embryocidal in rats. ■ Temporarily discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

No age-related differences observed. Median age in clinical trials was 65 years. ■ Lower-end initial doses may be indicated; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Should not be given concurrently with **Class Ia antiarrhythmics** (e.g., disopyramide, procainamide, quinidine) **or other Class III antiarrhythmics** (e.g., amiodarone, sotalol). Withhold any of these agents for at least 5 half-lives before ibutilide infusion and for 4 hours after. ■ Incidence of arrhythmia may be increased with **other drugs that prolong the QT interval** (e.g., phenothiazines [e.g., promethazine], tricyclic antidepressants [e.g., amitriptyline], tetracyclic antidepressants [e.g., maprotiline]). ■ Monitor **serum digoxin levels** to avoid digoxin toxicity. ■ Use with **digoxin, beta-blockers, or calcium channel blockers** does not alter safety or effectiveness of ibutilide. However, **sotalol** is a beta-blocker, and its use with ibutilide is restricted because it has Class III antiarrhythmic activity; see first sentence above.

SIDE EFFECTS

Sustained polymorphic VT (1.7%) and nonsustained polymorphic VT (2.7%) can deteriorate into ventricular fibrillation and be fatal. May cause many other arrhythmias (e.g., first-, second-, or third-degree AV block [1.5%], bradycardia [1.2%], bundle branch block [1.9%], nonsustained monomorphic VT [4.9%], prolonged QT segment [1.2%], PVCs [5.1%], tachycardia [2.7%]), CHF (0.5%), headache (3.6%), hypertension (1.2%), hypotension (2%), nausea (1.9%), palpitation (1%).

Overdose:

Side effects exaggerated with overdose in humans. Acute overdose in animals resulted in CNS depression, rapid gasping breathing, convulsions.

ANTIDOTE

If proarrhythmias occur, discontinue ibutilide; correct electrolyte abnormalities (e.g., potassium and magnesium). Overdrive cardiac pacing, electrical cardioversion, or defibrillation may be required. Infusions of magnesium sulfate may be helpful. Avoid treatment with antiarrhythmic agents. VT that deteriorates to VF will require immediate defibrillation.

IDARUBICIN HYDROCHLORIDE BBW

(eye-dah-**ROOB**-ih-sin hy-droh-**KLOR**-eyed)
Idamycin PFS, Idarubicin PFS, IDR
Antineoplastic (anthracycline antibiotic)
pH 5 to 7

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Adult acute myeloid leukemia (AML) induction therapy:

Induction:

Idarubicin 12 mg/M^2/day for 3 days. Used in combination with cytarabine (Ara-C). Cytarabine 100 mg/M^2/day may be given as a continuous infusion on Days 1 to 7 (daily for 7 days), or alternately the cytarabine may be given as an IV injection of 25 mg/M^2 followed immediately by a continuous infusion of cytarabine 200 mg/M^2/day on Days 1 to 5 (daily for 5 days). See Precautions/Monitor. If unequivocal evidence of leukemia remains after the first course, a second course may be given; see Dose Adjustments. The benefit of an aggressive consolidation and maintenance program in prolonging the duration of remissions and survival has not been proven. See prescribing information for regimens used in clinical trials.

DOSE ADJUSTMENTS

Delay second course until full recovery if severe mucositis has occurred and reduce dose by 25%. ■ Consider dose reductions in impaired liver and kidney function based on bilirubin and/or creatinine levels above the normal range. Do not administer if bilirubin is above 5 mg/dL. In one Phase III clinical trial, patients with bilirubin levels between 2.6 and 5 mg/dL received a 50% reduction in dose.

DILUTION

Specific techniques required (see **Precautions**).

Idamycin PFS is a liquid formulation; each 5 mg of powdered idamycin must be reconstituted with 5 mL of nonbacteriostatic NS for injection (1 mg/mL). Use extreme caution inserting the needle; vial contents are under negative pressure. Avoid any possibility of inhalation from aerosol or any skin contamination.

Filters:

No data available from manufacturer.

Storage:

PFS product must be refrigerated. Reconstituted idamycin is stable for 7 days under refrigeration (2° to 8° C [36° to 46° F]) or 3 days (72 hours) at room temperature (15° to 30° C [59° to 86° F]). Discard unused solution appropriately.

COMPATIBILITY

Manufacturer states, "Should not be mixed with other drugs unless specific **compatibility** data are available," and lists as **incompatible** with heparin. Prolonged contact with solutions of an alkaline pH (e.g., sodium lactate, sodium bicarbonate) will result in degradation of idarubicin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose of properly diluted medication over 10 to 15 minutes through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS.

ACTIONS

A highly toxic, synthetic, antibiotic, antineoplastic agent. An analog of daunorubicin. Rapidly distributed; has an increased rate of cellular uptake compared to other anthracyclines. It inhibits synthesis of DNA and interacts with the enzyme topoisomerase II. Results in a greater number of remissions and longer survival than previous protocols (daunorubicin and cytarabine). It is severely immunosuppressive. Extensive extrahepatic metabolism. Half-life averages 20 to 22 hours. Slowly excreted in bile and urine.

INDICATIONS AND USES

Treatment of acute myeloid leukemia (AML) in adults in combination with other approved antileukemic drugs.

Unlabeled uses:

Treatment of acute lymphoblastic leukemia in pediatric patients; see Maternal/Child.

CONTRAINDICATIONS

Not absolute; pre-existing bone marrow suppression, impaired cardiac function, preexisting infection; see Precautions/Monitor. ■ Do not administer if bilirubin above 5 mg/dL.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist, with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only. Do not give IM or SC. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, previous treatment with other anthracyclines (e.g., daunorubicin), other cardiotoxic agents (e.g., bleomycin), or radiation therapy encompassing the heart. ■ Myocardial toxicity may cause potentially fatal acute congestive heart failure, acute life-threatening arrhythmias, or other cardiomyopathies. Cardiac toxicity is more common in patients who have received prior anthracyclines (e.g., doxorubicin) or who have pre-existing cardiac disease. Risk of myocardial toxicity may be higher after concomitant or previous radiation to the mediastinal-pericardial area; or in patients with anemia, bone marrow depression, infections, leukemic pericarditis and/or myocarditis, active or dormant cardiovascular disease, previous therapy with other anthracyclines or anthracenediones; or with concomitant use of drugs with the ability to suppress cardiac contractility or cardiotoxic drugs (e.g., cyclophosphamide, paclitaxel, and trastuzumab). See Drug/Lab Interactions. ■ May cause severe myelosuppression. ■ Use with caution in patients with hepatic or renal dysfunction. Metabolism and excretion of idarubicin may be impaired; see Dose Adjustments.

Monitor:

Determine absolute patency of vein. A stinging or burning sensation indicates extravasation, but extravasation may occur without stinging or burning; severe cellulitis and tissue necrosis can occur with extravasation. Discontinue injection; use another vein. ■ Monitoring of WBCs, RBCs, platelet count, liver function, kidney function, ECG, chest x-ray, echocardiography, and systolic ejection fraction indicated before and during therapy. ■ Severe myelosuppression occurs with effective therapeutic doses. Observe closely for all signs of infection or bleeding. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor uric acid levels; maintain hydration; uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may be indicated. ■ See Precautions.

Patient Education:

Effective birth control recommended. ■ Report IV site burning or stinging promptly. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. May produce teratogenic effects on the fetus. Effective contraceptive measures indicated during childbearing years. ■ Discontinue breast-feeding before taking idarubicin. ■ Safety and efficacy for use in pediatric patients not established but has been used; consult literature.

Elderly:

Cardiotoxicity or myelotoxicity may be more severe. Patients over 60 years of age who were undergoing induction experienced CHF, serious arrhythmias, chest pain, myocardial infarction, and asymptomatic declines in left ventricular ejection fraction more frequently than younger patients. ■ Monitor renal, hepatic, and hematologic functions closely.

DRUG/LAB INTERACTIONS

Bone marrow toxicity is additive with **other chemotherapeutic agents.** ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin, mitoxantrone), **radiation encompassing the heart**, and/or **cardiotoxic drugs** (e.g., cyclophosphamide, paclitaxel, and trastuzumab). Due to the increased risk of cardiotoxicity, avoid concomitant use of idarubicin until the cardiotoxic agent has been discontinued for at least 5 half-lives, and specifically avoid idarubicin for up to 7 months after stopping trastuzumab. ■ Leukopenic and/or thrombocytopenic effects may be increased with **drugs that cause blood dyscrasias** (e.g., anticonvulsants [e.g., carbamazepine, phenytoin], NSAIDs [e.g., ibuprofen, naproxen]). Adjust dose based on differential and platelet count. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ See Precautions/Monitor.

SIDE EFFECTS

Acute congestive heart failure, alopecia (reversible), arrhythmias, bone marrow suppression (marked with average doses), cramping, decrease in systolic ejection fraction, depressed QRS voltage, diarrhea, erythema and tissue necrosis (if extravasation occurs), fever, headache, hemorrhage (severe), hepatic function changes, infection, mucositis, myocarditis, nausea, pericarditis, renal function changes, seizures, skin rash, urticaria (local), vomiting.

ANTIDOTE

Most side effects will be tolerated or treated symptomatically. Keep physician informed. Close monitoring of bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal side effects. There is no specific antidote, but adequate supportive care including platelet transfusions, antibiotics, and symptomatic treatment of mucositis is required. For extravasation, elevate the extremity and apply intermittent ice packs over the area immediately and 4 times a day for ½ hour. Continue for 3 days. Consider aspiration of as much infiltrated drug as possible, flooding of the site with NS, and injection of hydrocortisone sodium succinate (Solu-Cortef) throughout extravasated tissue. Use a 27- or 25-gauge needle. Site should be observed promptly by a reconstructive surgeon. If ulceration begins or there is severe persistent pain at the site, early wide excision of the involved area will be considered. Hemodialysis or peritoneal dialysis probably not effective in overdose.

IDARUCIZUMAB

(**EYE**-da-roo-**KIZ**-ue-mab)
Praxbind
Antidote

Monoclonal antibody
pH 5.3 to 5.7

USUAL DOSE

5 Gm provided as two separate vials, each containing 2.5 Gm/50 mL. There are limited data to support administration of an additional 5-Gm dose of idarucizumab; see Precautions.

DOSE ADJUSTMENTS

No dose adjustment is required in renally impaired patients. ■ Formal studies in patients with hepatic impairment have not been conducted.

DILUTION

A colorless to slightly yellow, clear to slightly opalescent solution available as a 2.5 Gm/50 mL injection in a single-use vial. Administer undiluted by withdrawing and injecting the contents of 2 vials with a syringe or by hanging and infusing the contents of 2 vials.

Filter:

Specific information not available.

Storage:

Store unopened vials in the refrigerator at 2° to 8° C (36° to 46° F). Do not freeze. Do not shake. Before use, the unopened vial may be kept at RT 25° C (77° F) for up to 48 hours if stored in the original package to protect from light, or up to 6 hours when exposed to light. Once solution has been removed from the vial, administration should begin promptly or within 1 hour.

COMPATIBILITY

Manufacturer states, "Do not mix with other medicinal products. A pre-existing IV line may be used for administration. The line must be flushed with NS prior to infusion. No other infusion should be administered in parallel via the same IV access."

RATE OF ADMINISTRATION

Administer by bolus injection by injecting both vials consecutively one after another via syringe. Alternatively, may administer as two rapid consecutive infusions by hanging and infusing each vial one after another. Flush IV line with NS before administration of idarucizumab.

ACTIONS

A recombinant humanized monoclonal antibody fragment (Fab); it is derived from an IgG1 isotype molecule whose target is the direct thrombin inhibitor dabigatran. Idarucizumab is a specific reversal agent for dabigatran. It binds to dabigatran and its acylglucuronide metabolites with a higher affinity than the binding affinity of dabigatran to thrombin, thereby neutralizing their anticoagulant effect. In studies, the plasma concentrations of unbound dabigatran were reduced to below the lower limit of quantification immediately after the administration of 5 Gm idarucizumab. Subjects' diluted thrombin time (dTT), ecarin clotting time (ECT), activated partial thromboplastin time (aPTT), thrombin time (TT), and activated clotting time (ACT) parameters returned to baseline levels. Idarucizumab is rapidly eliminated with an initial half-life of 47 minutes and a terminal half-life of 10.3 hours. Some drug is recovered in the urine. The remaining part of the dose is assumed to be eliminated via protein catabolism, mainly in the kidney. Idarucizumab is thought to be metabolized via pathways that involve the biodegradation of the antibody to smaller peptides or amino acids, which are then reabsorbed and incorporated in the general protein synthesis.

INDICATIONS AND USES

Reversal of the anticoagulant effects of dabigatran (Pradaxa) when reversal is needed for emergency surgery/urgent procedures or in life-threatening or uncontrolled bleeding.

CONTRAINDICATIONS

Manufacturer states, "None."

PRECAUTIONS

For IV use only. ■ Idarucizumab treatment should be used in conjunction with standard supportive measures. ■ Reversing dabigatran therapy exposes patients to the thrombotic risk of their underlying disease. To reduce this risk, resumption of anticoagulant therapy should be considered as soon as medically appropriate. Dabigatran treatment can be initiated 24 hours after administration of idarucizumab. No changes in the pharmacokinetics or pharmacodynamics of dabigatran were noted upon re-initiation 24 hours after administration of idarucizumab. ■ Elevated coagulation parameters (e.g., activated partial thromboplastin time [aPPT], ecarin clotting time [ECT]) have been observed between 12 and 24 hours after administration of a 5-Gm dose of idarucizumab in a limited number of patients. Administration of an additional 5-Gm dose of idarucizumab may be considered if the reappearance of clinically relevant bleeding together with elevated coagulation parameters is observed after administration of the initial dose. Similarly, patients who require a second emergency surgery/urgent procedure and have elevated coagulation parameters may receive an additional 5-Gm dose of idarucizumab. The safety and effectiveness of repeat treatment with idarucizumab have not been established. ■ Adverse events possibly indicative of hypersensitivity reactions have been reported. The risk of using idarucizumab in a patient with known hypersensitivity to idarucizumab (e.g., anaphylactoid reaction) or to any of its excipients needs to be weighed cautiously against the potential benefit of such an emergency treatment. If an anaphylactic reaction or other serious reaction occurs, immediately discontinue administration of idarucizumab. ■ The recommended dose of idarucizumab contains 4 Gm of sorbitol as an excipient. Patients with the condition of hereditary fructose intolerance (HFI) have experienced serious adverse reactions (e.g., acute liver failure, hypoglycemia, hypophosphatemia, increase in uric acid, metabolic acidosis) after receiving parenteral administration of sorbitol. When prescribing idarucizumab to patients with HFI, consider the combined daily metabolic load of sorbitol/fructose from all sources, including idarucizumab and other drugs containing sorbitol. The minimum amount of sorbitol at which serious adverse reactions may occur in these patients is not known. ■ Idarucizumab is a specific reversal agent for dabigatran, with no impact on the effect of other anticoagulant or antithrombotic therapies. ■ As with all proteins, there is a potential for immunogenicity with idarucizumab. Pre-existing antibodies with cross-reactivity to idarucizumab were detected in some subjects. No impact on the pharmacokinetics or the reversal effect of idarucizumab or on hypersensitivity reactions was observed in these subjects.

Monitor:

Monitor coagulation parameters (e.g., aPPT and ECT [if available]). ■ Monitor for S/S of clinically relevant bleeding and thromboembolic events. ■ Monitor for S/S of hypersensitivity reactions (e.g., bronchospasm, fever, pruritus, rash).

Patient Education:

Increased thromboembolic risk with reversal of dabigatran. Resume anticoagulant therapy as directed when deemed stable. ■ Seek immediate medical attention for any S/S of bleeding. ■ Seek immediate medical attention for S/S of a hypersensitivity reaction (e.g., rash, wheezing). Reactions may occur during or after administration of idarucizumab. ■ Inform patients with HFI that idarucizumab contains sorbitol. Adverse reactions related to the parenteral administration of sorbitol may occur during or after administration and should be promptly reported.

Maternal/Child:

Data unavailable. Administer during pregnancy only if clearly needed. ■ Safety and effectiveness during labor and delivery have not been studied. ■ Use caution during breast-feeding; risk to infant unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or effectiveness have been observed between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ In vitro data suggest that the inhibition of dabigatran by idarucizumab is not affected by coagulation factor concentrates (3-factor or 4-factor prothrombin complex concentrates [PCCs], activated PCC, or recombinant factor VIIa).

SIDE EFFECTS

The most frequently reported adverse reactions were constipation, headache, and nausea. Hypersensitivity reactions (e.g., bronchospasm, fever, hyperventilation, pruritus, and rash) and thromboembolic events have been reported. Most patients experiencing a thrombotic event were not on antithrombotic therapy at the time of the event.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue administration at the first sign of a serious hypersensitivity reaction and treat as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

IDURSULFASE BBW

(eye-dur-**SUL**-face)
Elaprase
Enzyme replenisher
pH 6

USUAL DOSE

Pretreatment:

Evaluate airway patency; see Monitor.

Idursulfase:

0.5 mg/kg of body weight as an infusion once each week.

Premedication:

If a severe infusion reaction occurs, pretreatment with antihistamines (e.g., diphenhydramine) and/or corticosteroids may be indicated for subsequent infusions before or during the infusion.

PEDIATRIC DOSE

Pediatric patients 5 years of age or older:

See Usual Dose. Pediatric patients younger than 5 years of age were not included in clinical trials.

DOSE ADJUSTMENTS

None indicated.

DILUTION

Each vial contains 6 mg (3 mL [2 mg/mL]) of idursulfase. Determine the total volume of idursulfase to be administered (mL required) and the number of vials required with the following formula:

Weight in kg × 0.5 mg/kg of idursulfase ÷ 2 mg/mL = Total mL of idursulfase required

Total # mL idursulfase required ÷ 3 mL/vial = Total # of vials required

For example, a patient weighing 40 kg would receive a 20-mg dose (40 kg × 0.5 mg/kg = 20-mg. 20-mg ÷ 2 mg/mL = 10 mL). 10 mL divided by 3 mL (# of mL/vial) equals 3.33 vials. If more than one vial is required, round up to the next whole vial number; therefore 4 vials are required in this example. Handle vials carefully; ***avoid shaking or agitation.***

Solution in vials should be colorless and clear to slightly opalescent. Next, slowly withdraw the calculated dose (volume) of drug from the required vials and add to 100 mL of NS. Gently rotate the infusion bag to ensure proper mixing. ***Avoid shaking or agitation.***

Filters:

Fully diluted solution should be filtered through an in-line, low–protein binding, 0.2-micron filter for administration.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F) and protect from light. Do not use after the expiration date on the vial. ***Do not freeze or shake.*** Immediate use of vials after removal from refrigeration is recommended. The diluted solution should be used immediately or refrigerated for up to 24 hours. Should be at RT only during the actual infusion time. Complete infusion within 8 hours. For single use only in vials or in solution; discard unused drug.

COMPATIBILITY

Manufacturer states, “Must not be infused with other products in the infusion tubing.”

RATE OF ADMINISTRATION

Fully diluted solution should be administered with an infusion set equipped with an in-line, low–protein binding, 0.2-micron filter. Infusion reactions may occur even when patients have been premedicated. Administration as a controlled IV infusion using an infusion pump is appropriate.

Begin the infusion with a rate of 8 mL/hr for the first 15 minutes. Should an infusion reaction occur, further decrease this rate or discontinue until symptoms subside. Premedication may be indicated. If the infusion is well tolerated, the rate may be increased in 8 mL/hr increments at 15-minute intervals. Do not exceed a rate of 100 mL/hr. The desired length of infusion is 3 hours. Infusion time may be gradually reduced to 1 hour if no hypersensitivity reactions occur. Extended infusion times may be required if hypersensitivity reactions occur but should not exceed 8 hours (see Storage).

ACTIONS

A recombinant form of iduronate-2-sulfatase (a human lysosomal enzyme). Produced by genetic engineering. Mucopolysaccharide storage disorders are caused by a deficiency of specific lysosomal enzymes required for the catabolism of glycosaminoglycans (GAG). Deficiency of iduronate-2-sulfatase activity results in the accumulation of GAG throughout the body. This accumulation leads to widespread cellular, tissue, and organ dysfunction. Idursulfase provides an exogenous enzyme for uptake into cellular lysosomes and increases the catabolism of GAG. Mean half-life was 44 to 160 minutes. Bioactivity can be evaluated with urinary GAG concentrations. Urinary GAG concentrations decrease in patients receiving idursulfase; however, normal urinary GAG concentrations have not been achieved.

INDICATIONS AND USES

Treatment of patients with Hunter syndrome (mucopolysaccharidosis type II [MPS II]). Has been shown to improve walking capacity in patients 5 years of age and older.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. Life-threatening anaphylactic reactions have occurred in some patients during and up to 24 hours after idursulfase infusions. Anaphylaxis presenting as respiratory distress, hypoxia, hypotension, angioedema of the throat or tongue, and/or urticaria has occurred during and after idursulfase infusions regardless of duration of the course of treatment and may occur after recovery from an initial anaphylactic reaction that occurred during the infusion. ■ Consider patient’s clinical status before administration of idursulfase; patients with an underlying respiratory illness may be at increased risk of experiencing acute respiratory failure or an infusion reaction. Consider delaying the infusion. ■ Patients susceptible to fluid overload, or patients with acute underlying respiratory illness or compromised cardiac and/or respiratory function for whom fluid restriction is indicated, may be at risk for serious exacerbation of their cardiac or respiratory status during infusion. ■ Patients with MPS II may have pre-existing upper airway obstruction, are prone to sleep apnea, and may be at increased risk for infusion reactions; monitor closely. ■ With proper premedication and adjustment in the rate of administration, most patients with previous infusion reactions are able to continue therapy. ■ Many patients develop anti-idursulfase IgG antibodies and may have an increased incidence of infusion/hypersensitivity reactions and a reduction of urinary GAG excretion. The effect on clinical effectiveness is unknown.

Monitor:

Monitor V/S frequently. ■ Evaluate airway patency before initiating treatment. ■ Observe patient continuously for symptoms of infusion-related or hypersensitivity reactions during and after idursulfase administration, and be prepared to manage anaphylaxis. Initial infusion/hypersensitivity reactions can occur at any time during treatment and may occur in patients who have not had reactions with previous injections. Prolonged patient observation is indicated in patients who experience an initial severe or refractory infusion/hypersensitivity reaction; repeat reactions have been reported to occur up to 24 hours after treatment. Cutaneous reactions (erythema, pruritus, rash, urticaria), fever, headache, and hypertension are most common. Severe symptoms may include angioneurotic edema, hypotension, hypoxia, and respiratory distress. See Precautions and Antidote. ■ Monitor patients with compromised respiratory function and/or cardiac function or acute respiratory disease closely; may be at risk for serious acute exacerbation of their respiratory or cardiac compromise due to infusion reactions. ■ Numerous other baseline tests and specific monitoring of airway, cardiac, circulatory, and renal function may be indicated based on the degree of progression of each patient's MPS II disease. ■ Patients with MPS II are usually shorter than their peers and have a large head, distinct facial features, and an enlarged abdomen. The syndrome affects mainly males and may lead to hearing loss, thickening of the heart valves with a decline in cardiac function, obstructive airway disease, sleep apnea, enlargement of the liver and spleen, and central nervous system involvement that may lead to progressive neurologic decline and death by 10 to 15 years of age. Without CNS involvement, some patients live to 50 or 60 years of age.

Patient Education:

Promptly report early symptoms of a hypersensitivity or infusion reaction (e.g., chills or rigors, fever, flushing, headache, itching, rash, shortness of breath). ■ Shire has established a registry and encourages all patients to participate to further evaluate the effects of therapy with possible long-term follow-up.

Maternal/Child:

Use during pregnancy only if clearly needed. Effects on the fetus are unknown. ■ Effects during breast-feeding are unknown; use caution. See registry information in Patient Education. ■ No data are available to demonstrate improvement in disease-related symptoms or long-term clinical outcome in patients 16 months to 5 years of age; however, spleen volume has been reduced similarly to that of adults and pediatric patients 5 years of age and older. ■ Safety and effectiveness in pediatric patients younger than 16 months of age not established.

Elderly:

Patients older than 31 years of age were not included in studies; response in older patients unknown. Consider limited life expectancy of patients with MPS II disease.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

Hypersensitivity reactions occur frequently and may be life threatening. Cutaneous reactions (erythema, flushing, pruritus, rash, urticaria), fever, headache, and hypertension are most common. Hypersensitivity reactions, including anaphylaxis, angioedema, apnea, bronchospasm, dyspnea, hypotension, hypoxic episodes, and respiratory distress, are the most serious adverse events. Abscess, anxiety, chest wall musculoskeletal pain, cough, diarrhea, dizziness, dyspepsia, infusion site edema, irritability, limb pain, malaise, nausea and vomiting, visual disturbances, and wheezing have been reported. Arthralgia, cardiac arrhythmia, cyanosis, infection, and pulmonary embolism have also been reported.

Post-Marketing:

Anaphylactic reactions have occurred up to several years after initiating treatment. Some patients had repeated anaphylactic events over a 2- to 4-month time period. Cardiorespiratory arrest, cardiac failure, pneumonia, respiratory distress, and respiratory failure resulting in death have been reported.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. If a severe hypersensitivity or anaphylactic reaction occurs, discontinue idursulfase immediately and treat as indicated (e.g., epinephrine, corticosteroids, inhaled beta-adrenergic agonists [e.g., albuterol]). If a mild to moderate infusion or hypersensitivity reaction occurs, reduce rate or discontinue idursulfase until symptoms subside. Additional antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen) may be indicated. Treatment and/or premedication with corticosteroids (e.g., dexamethasone) may be indicated based on the severity of infusion reactions. With additional premedication and/or a reduction in rate of infusion, patients may be able to continue treatment. Resuscitate as necessary.

IFOSFAMIDE BBW

(eye-**FOS**-fah-myd)
Ifex
Antineoplastic (alkylating agent/nitrogen mustard)
pH 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting, baseline studies, and adequate hydration required; see Precautions and Monitor.

1.2 Gm/M^2/day for 5 consecutive days. Repeat every 3 weeks as hematologic recovery permits. To prevent hemorrhagic cystitis, ifosfamide should be given with extensive hydration (e.g., at least 2 liters of oral or IV fluid/day), and mesna should be administered with every dose; see Compatibility.

DOSE ADJUSTMENTS

Reduced dose may be required in renal or hepatic impairment. Adequate data not available. ■ Dosing should be cautious in the elderly. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy. See Elderly. ■ Severe myelosuppression is frequent, especially when ifosfamide is given with other chemotherapeutic agents. Dose adjustments of all agents may be required. Adjustment of dose interval may be required. Unless clinically essential, ifosfamide should be held for WBCs less than 2,000/mm^3 and/or platelets less than 50,000/mm^3. See Monitor and Drug/Lab Interactions.

DILUTION

Specific techniques required; see Precautions.

Each 1 Gm must be diluted with 20 mL SWFI or bacteriostatic water for injection (parabens or benzyl alcohol preserved only). 1 Gm in 20 mL or 3 Gm in 60 mL equals 50 mg/mL; shake solution to dissolve. May be further diluted with D5W, NS, LR, or SWFI to a final concentration of 0.6 to 20 mg/mL. Further dilution with D2½W, ½NS, and D5NS is also acceptable for larger volumes. 1 Gm in 50 mL equals 20 mg/mL; 1 Gm in 200 mL equals 5 mg/mL.

Filters:

Studies measured potency of ifosfamide in combination with mesna through a 5-micron filter. No significant drug loss for ifosfamide; mesna was not measured.

Storage:

Store at CRT 20° to 25° C (68° to 77° F). Protect from temperatures above 30° C (86° F). Reconstituted and further diluted solution should be refrigerated and used within 24 hours. Solutions containing benzyl alcohol can reduce stability.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over a minimum of 30 minutes as an infusion. Extend administration time based on amount of diluent and patient condition.

ACTIONS

An alkylating agent. Chemically related to the nitrogen mustards and a synthetic analog of cyclophosphamide. A prodrug that requires activation by hepatic cytochrome P_{450} isoenzymes to exert its cytotoxic activity. Exact mechanism of action not determined, but its cytotoxic action is primarily through DNA cross-links caused by alkylation by isophosphoramide mustard at guanine N7 positions. The formation of inter- and intra-strand cross-links in the DNA results in cell death. Distribution takes place with minimal tissue binding. Plasma protein binding is negligible. Extensively bound by red blood cells. Extensively metabolized in the liver (considerable individual variation). Elimination half-life for a usual dose is about 7 hours. Half-life is extended with larger doses. Ifosfamide and its metabolites are excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Used in combination with other specific antineoplastic agents for third-line chemotherapy of germ cell testicular cancer. Should be used in combination with mesna for prophylaxis of hemorrhagic cystitis.

Unlabeled uses:

Bladder, cervical, and ovarian cancers; Ewing's sarcoma; Hodgkin and non-Hodgkin lymphoma; osteosarcoma; soft tissue sarcomas.

CONTRAINDICATIONS

Hypersensitivity to ifosfamide; urinary outflow obstruction.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist. ■ Exclude or correct any urinary tract obstructions; see Contraindications. ■ Myelosuppression can be severe and lead to fatal infections. Deaths have been reported. Risk of myelosuppression is dose-dependent and is increased in patients with reduced renal function and when ifosfamide is administered as a single high dose compared to fractionated doses. Severe myelosuppression is often observed when ifosfamide is used in combination with other chemotherapeutic/hematotoxic agents and/or radiation therapy. ■ Administer cautiously, if at all, to patients with an infection (including an active urinary tract infection), severe immunosuppression, or compromised bone marrow reserve as indicated by leukopenia, granulocytopenia, extensive bone marrow metastases, prior radiation therapy, or prior treatment with other cytotoxic agents. ■ CNS toxicities can be severe and result in encephalopathy and death. ■ Nephrotoxic and urotoxic. Acute tubular necrosis, acute renal failure, and chronic renal failure have been reported, and deaths have occurred. Benefits must outweigh risks if ifosfamide is used in patients with pre-existing renal impairment or reduced nephron reserve. Glomerular and tubular disorders of renal function are common and may become apparent during therapy or months and years after stopping treatment. They may resolve, remain stable, or progress even after completion of treatment. Hemorrhagic cystitis can be severe and may require blood transfusions. Urotoxic effects can be reduced by the prophylactic use of mesna. Risk of hemorrhagic cystitis is dose-dependent and increases with the administration of single high doses compared to fractionated administration. Past or concomitant radiation of the bladder or busulfan therapy may also increase risk. ■ Use caution in patients with risk factors for cardiotoxicity or pre-existing cardiac disease. Cardiotoxicity (e.g., supraventricular or ventricular arrhythmias, decreased QRS voltage and ST-segment or T-wave changes, toxic cardiomyopathy leading to heart failure with congestion and hypotension, pericardial effusion, fibrinous pericarditis, epicardial fibrosis), sometimes with fatal outcomes, has been reported. Risk is dose dependent and is increased with prior or concomitant treatment with other cardiotoxic agents or radiation of the cardiac region and, possibly, renal impairment. ■ Pulmonary toxicity (e.g., interstitial pneumonitis, pulmonary fibrosis, and other forms of pulmonary toxicity) has been reported, sometimes with fatal outcomes. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Cross-sensitivity between oxazaphosphorine cytotoxic agents (e.g., cyclophosphamide) has been reported. ■ May interfere with normal wound healing. ■ Risk of secondary malignancies is increased. ■ Veno-occlusive liver disease has been reported. ■ Studies in patients with hepatic or renal impairment have not been conducted. Use with caution.

Monitor:

Monitor CBC with differential and platelet count before each daily dose and at intervals after each treatment cycle. Unless clinically essential, WBC count should be above 2,000/mm^3 and platelet count above 50,000/mm^3. ■ Nadir of the leukocyte count tends to be reached during the second week after administration. ■ Evaluate glomerular and tubular kidney function before, during, and after treatment. ■ Monitor urinary sediment regularly for erythrocytes and other signs of urotoxicity/nephrotoxicity. ■ Urinalysis before each dose recommended. Withhold drug if RBCs in urine exceed 10 per high-powered field. Reinstitute after complete resolution with vigorous oral or parenteral hydration. Mesna given concurrently should help prevent hemorrhagic cystitis. ■ Monitor serum and urine chemistries, including phosphorus and potassium, regularly; administer replacement as indicated. ■ Monitor for S/S of renal dysfunction (e.g., decreased glomerular filtration rate, increased SCr, aminoaciduria, cylindruria, enzymuria, glycosuria, phosphaturia, proteinuria, and tubular acidosis). ■ Adequate hydration required; encourage fluid intake (minimum of 2 L/day) and frequent voiding to prevent cystitis. ■ Monitor for S/S of hypersensitivity (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Monitor for S/S of pulmonary toxicity and treat as indicated. ■ Pneumonias, as well as other bacterial, fungal, viral, and parasitic infections, have been reported, and latent infections can be reactivated. Observe constantly for signs of infection (e.g., fever, sore throat, tiredness) or unusual bleeding or bruising. Antimicrobial prophylaxis may be indicated in certain cases of neutropenia. Antibiotics and/or antimycotics must be given if neutropenic fever occurs. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for CNS toxicity. Blurred vision, coma, confusion, extrapyramidal symptoms, hallucinations, psychotic behavior, seizures, somnolence, and urinary incontinence have been reported. Peripheral neuropathy has also been reported. Neurotoxicity may appear within a few hours to a few days after the first administration and usually resolves within 48 to 72 hours of discontinuing ifosfamide, although symptoms may persist. Recurrence after several uneventful treatment courses has occurred. Discontinue treatment if encephalopathy occurs. ■ Prophylactic administration of antiemetics recommended. ■ See Drug/Lab Interactions.

Patient Education:

Effective birth control recommended. Females should avoid pregnancy during therapy, and males should not father a child during therapy and for up to 6 months after the end of therapy. ■ Interferes with oogenesis and spermatogenesis. May cause amenorrhea in females and oligospermia or azoospermia in males. Sterility has been reported. See

Maternal/Child. ■ Review medical history and medications with provider. ■ Frequent laboratory monitoring required. ■ CNS toxicity may impair the ability to operate an automobile or other heavy machinery. ■ Adequate hydration (at least 2 L/day) and frequent voiding are required to help prevent bladder toxicity. ■ Side effects are numerous and may be fatal; review all potential side effects with your health care professional before treatment. ■ Promptly report any side effects, including S/S of infection, hypersensitivity reactions, GI toxicity, CNS toxicity, pulmonary toxicity, stomatitis, blood in urine, bleeding, bruising, or visual/auditory disorders. ■ See Appendix D, p. 1311.

Maternal/Child:

Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Fanconi syndrome, renal rickets, and growth retardation have been reported in pediatric patients. Prepubescent females may become sterile or are at risk for developing premature menopause. Prepubescent males may not develop secondary sexual characteristics normally and may have oligospermia or azoospermia.

Elderly:

Consider age-related organ impairment. Dose selection should be cautious; see Dose Adjustments. Monitor renal, hepatic, and hematologic functions closely.

DRUG/LAB INTERACTIONS

See Dose Adjustments. ■ A substrate for both CYP3A4 and CYP2B6. **CYP3A4 inducers** (e.g., carbamazepine, phenytoin, phenobarbital, rifampin, and St. John's wort) may increase the metabolism of ifosfamide to its active alkylating metabolites and increase the formation of the neurotoxic/nephrotoxic metabolite chloroacetaldehyde. Monitor closely for signs of toxicity; consider dose adjustment. **CYP3A4 inhibitors** (e.g., aprepitant, fluconazole, grapefruit and grapefruit juice, itraconazole, ketoconazole, sorafenib) may decrease the metabolism of ifosfamide to its active alkylating metabolites, perhaps decreasing the effectiveness of treatment. ■ May have additive effects with **other drugs that act on the CNS** (e.g., antihistamines, antiemetics, narcotics, or sedatives). Use with caution or discontinue if encephalopathy occurs. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Hematuria, hemorrhagic cystitis, and bone marrow suppression are dose-limiting side effects. The most common side effects included alopecia, anemia, CNS toxicity (see Monitor), hematuria, infection, leukopenia, nausea, and vomiting. Other commonly reported side effects were anorexia, constipation, and diarrhea. Cardiotoxicity (e.g., arrhythmias, CHF, pulmonary edema), dermatitis, fever of unknown origin, hypersensitivity reactions, hypertension, hypotension, liver dysfunction, malaise, neutropenia and neutropenic fever, peripheral neuropathy, phlebitis, pulmonary symptoms, rash, renal dysfunction (e.g., acute renal failure; anuria; increased BUN, SCr; oliguria), stomatitis, or thrombocytopenia, may occur.

Overdose:

Manifestations of dose-dependent toxicities such as CNS toxicity, mucositis, myelosuppression, nephrotoxicity.

Post-Marketing:

Anaphylaxis; angioedema; benign and malignant neoplasms; hematotoxicity (e.g., agranulocytosis, bone marrow failure, DIC, febrile bone marrow aplasia, hemolytic anemia, hemolytic uremic syndrome, methemoglobinemia, neonatal anemia); infections, including reactivation of latent infections (e.g., herpes zoster, *Pneumocystis jiroveci,* progressive multifocal leukoencephalopathy [PML], *Strongyloides,* viral hepatitis, and other viral and fungal infections); pneumonia; sepsis and septic shock (including fatal outcomes); psychiatric disorders; syndrome of inappropriate antidiuretic hormone secretion (SIADH); tumor lysis syndrome; and numerous other serious side effects have been reported.

ANTIDOTE

Minor side effects will be treated symptomatically if necessary. Discontinue ifosfamide and notify physician immediately if hematuria, hemorrhagic cystitis, WBC below 2,000 mm^3, or platelets below 50,000/mm^3 occur. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow suppression. Maintain supportive therapy for CNS symptoms until complete resolution; occasionally, recovery has been incomplete. Discontinue treatment if encephalopathy occurs. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Cystitis prophylaxis with mesna may prevent or limit urotoxic effects. Ifosfamide and its metabolites are dialyzable.

IMIGLUCERASE ■ VELAGLUCERASE ALFA

(em-ee-**GLUE**-sir-ace) ■ (vel-a-**GLOO**-ser-ase **AL**-fa)
Cerezyme ■ VPRIV
Enzyme replenisher (glucocerebrosidase)
Imiglucerase pH 6.1

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

Consider pretreatment with antihistamines (e.g., diphenhydramine) and/or corticosteroids (e.g., dexamethasone) in patients who exhibit symptoms of hypersensitivity associated with prior infusions.

Imiglucerase:

Adults and pediatric patients over 2 years of age:

Individualized to each patient based on the severity of illness and patient response. Initial doses range from 2.5 units/kg 3 times a week to 60 units/kg every 2 weeks.

Velaglucerase alfa:

Adult and pediatric patients 4 years of age and older naÏve to enzyme replacement therapy:

60 units/kg every other week. Patients currently being treated with a stable dose of imiglucerase may be switched to velaglucerase alfa at that same dose 2 weeks after the last imiglucerase dose.

DOSE ADJUSTMENTS

Both preparations:

Dose may increase or decrease based on achievement and maintenance of each patient's therapeutic goals. Optimal goal is to establish the lowest dose that is effective in maintaining control of the disease and preventing recurrence of symptoms for each patient. ■ Consider potential comorbid conditions and dose the elderly cautiously.

Imiglucerase:

To utilize each bottle fully and reduce waste, a single dose may be increased or decreased slightly as long as the total monthly dose remains unaltered.

DILUTION

Imiglucerase:

Available in 200-unit and 400-unit vials.

Velaglucerase:

Available in 400-unit vials.

Weight in kg × dose/kg desired ÷ (200 or 400 units/vial) = # of vials required

A 60-kg man requiring 60 units/kg would require 3,600 units. Number of vials required would be 18 vials at 200 units/vial or 9 vials at 400 units/vial. After patient is weighed and appropriate dose is calculated, remove sufficient vials from refrigerator.

Imiglucerase:

Adjust number of vials up or down within monthly dose requirement to fully utilize each vial. Each 200-unit vial must be reconstituted with 5.1 mL of SWFI. Each 400-unit vial must be reconstituted with 10.2 mL of SWFI. Both equal 40 units/mL. Gently swirl to mix the solution. ***Do not shake.*** Let stand for several minutes to allow product to dissolve and bubbles to dissipate. Withdraw exactly 5 mL from the 200-unit vial or 10 mL from the 400-unit vial. A total dose must be further diluted with NS to a volume of 100 to 200 mL. Do not use if discolored or opaque or if particulate matter is present.

After dilution, slight flocculation (thin translucent fibers) may occur.

Velaglucerase alfa:

Reconstitute each 400-unit vial with 4.3 mL SWFI. Equals 100 units/mL. Mix gently. ***Do not shake.*** Should be clear to slightly opalescent. Do not use if discolored or opaque or if particulate matter is present. Withdraw the calculated volume of drug from vials. Using a separate syringe, withdraw air from a bag of 100 mL of NS, then inject the total calculated dose into the NS solution. Mix gently. ***Do not shake.***

Filters:

Both preparations:

Administration through a low–protein binding, 0.2-micron in-line filter is recommended.

Storage:

Imiglucerase:

Refrigerate before use. Do not use after expiration date on bottle. Return of unsuitable vials (reconstituted, before reconstitution, or expired) may be authorized; contact manufacturer. Contains no preservative; do not store opened vials for future use. Should be promptly diluted after reconstitution but has been shown to be stable after reconstitution for up to 12 hours at RT or under refrigeration. Diluted solutions stable for up to 24 hours under refrigeration.

Velaglucerase alfa:

Refrigerate at 2° to 8° C (36° to 46° F) in carton before use. Do not use after expiration date on vial. Protect from light; do not freeze. Immediate use is preferred, but reconstituted and fully diluted solutions are stable for up to 24 hours if refrigerated and protected from light. Do not freeze. Complete infusion within 24 hours of reconstitution. For single use only; discard unused solution.

COMPATIBILITY

Imiglucerase:

Compatibility information not available from manufacturer; consult a pharmacist.

Velaglucerase alfa:

Manufacturer states, “Do not infuse with other products in the same infusion tubing.” **Compatibility** studies have not been done.

RATE OF ADMINISTRATION

Both preparations:

Use of an in-line, low–protein binding, 0.2-micron filter is recommended. Use of an infusion pump is helpful. Flush the IV line with NS at the end of the infusion to ensure the total dose is received.

Imiglucerase:

A single dose equally distributed over 1 to 2 hours.

Velaglucerase alfa:

A single dose equally distributed over 60 minutes.

ACTIONS

Imiglucerase is an analog of the human enzyme beta-glucocerebrosidase produced by recombinant DNA technology. **Velaglucerase alfa** is a hydrolytic lysosomal glucocerebroside-specific enzyme and is produced by gene activation technology in a human fibroblast cell line. Gaucher disease is characterized by a functional deficiency in beta-glucocerebrosidase enzymatic activity and the resultant accumulation of lipid glucocerebroside in tissue macrophages (Gaucher cells). These cells are found in the liver, spleen, bone marrow, and occasionally in the lung, kidney, and intestine. These agents act like glucocerebrosidase, catalyzing the hydrolysis of glucocerebroside to glucose and ceramide. Effective in controlling and actually reversing disease symptoms. Increase in appetite and energy level and improvement in hemoglobin are often the first observable effects and may occur in 2 to 4 months. Cachexia and wasting in pediatric patients are reduced. Within 6 months splenomegaly and hepatomegaly are significantly reduced, and hemoglobin, hematocrit, erythrocyte, and platelet counts improved. Replenishment of bone marrow and improving mineralization of bone may take several years.

INDICATIONS AND USES

Imiglucerase:

Long-term enzyme replacement therapy for pediatric and adult patients with confirmed diagnosis of Type 1 Gaucher disease, which results in one or more of the following conditions: anemia, thrombocytopenia, bone disease, hepatomegaly, or splenomegaly.

Velaglucerase alfa:

Long-term enzyme replacement therapy for pediatric and adult patients with Type 1 Gaucher disease.

CONTRAINDICATIONS

Imiglucerase:

None known. Reevaluate if there is significant clinical evidence of hypersensitivity to imiglucerase.

Velaglucerase alfa:

Manufacturer states, “None.”

PRECAUTIONS

Both preparations:

Hypersensitivity and infusion reactions have been reported. Administer further enzyme replacement therapy treatment with caution in patients who have exhibited symptoms of hypersensitivity to other enzyme replacement therapy; see Antidote. ■ Effective only via IV route. ■ Should be used under the direction of a physician knowledgeable in the management of Gaucher disease. Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency.

Imiglucerase:

Approximately 15% of patients have developed IgG antibodies. Most patients who develop antibodies to imiglucerase do so within 12 months of treatment. Patients with antibodies to imiglucerase are at increased risk for developing hypersensitivity reactions. Monitor periodically for IgG antibody formation during the first year of therapy. Patients who develop hypersensitivity reactions to imiglucerase may be premedicated (see Usual Dose and Antidote) or consideration may be given to treatment with velaglucerase alfa (VPRIV). ■ Pulmonary hypertension and pneumonia have been reported. They are known complications of Gaucher disease and have been observed in these patients whether or not they are receiving imiglucerase. Evaluate patients with respiratory symptoms in the absence of fever for the presence of pulmonary hypertension.

Velaglucerase alfa:

Hypersensitivity reactions, including anaphylaxis, have occurred. Symptoms were generally mild (e.g., asthenia, chest discomfort, dizziness, dyspnea, fatigue, fever, headache, hypertension, hypotension, nausea, pruritus, and vomiting) and usually occurred during the first 6 months of treatment and occurred less frequently with time. Patients who develop hypersensitivity reactions to velaglucerase may be premedicated (see Usual Dose and/or Antidote). Development of IgG antibodies has been rare but is possible.

Monitor:

Evaluate CBC with platelets, acid phosphatase (AP), liver enzymes, plasma glucocerebroside, liver and/or spleen size, and bone changes before and during therapy. Frequency determined by patient response; more frequent when determining response to initial dose and when dose is being adjusted. Blood tests will be done more frequently because anemia is the first symptom to improve. ■ Monitor weight before each dose (used to calculate dose) and monitor vital signs. ■ Observe for S/S of a hypersensitivity reaction; see Antidote. ■ MRI or CT may be used to evaluate liver and spleen. ■ Standard x-rays provide adequate evaluation of bone changes. ■ Evaluate patient closely for signs of improvement (e.g., increased energy, reduced bleeding tendency, reduction in size of liver and/or spleen, reduced joint swelling, reduced bone pain). ■ Continue to monitor for antibodies in patients who have developed an immune response to imiglucerase and are transferred to velaglucerase alfa. ■ See Precautions.

Patient Education:

Treatment required for life. ■ Promptly report S/S of a hypersensitivity or infusion reaction (e.g., chills, dizziness, fatigue, fever, headache, itching, nausea, rash, shortness of breath, wheezing).

Maternal/Child:

Both preparations:

Safety for use during breast-feeding not established. Not known if imiglucerase or velaglucerase are secreted in breast milk.

Imiglucerase:

Use in pregnancy only if potential benefit justifies the risk. ■ Has been used in pediatric patients under 2 years of age, but safety and effectiveness have not been established.

Velaglucerase alfa:

Category B: use in pregnancy only if clearly needed. Type 1 Gaucher disease manifestations may lead to adverse pregnancy outcomes. Women with Type 1 Gaucher disease have an increased risk of spontaneous abortion, especially if disease symptoms are not treated and controlled before conception and during pregnancy. ■ Disease manifestations may lead to adverse pregnancy outcomes, including hepatosplenomegaly, which can interfere with the normal growth of a pregnancy, and thrombocytopenia, which can lead to increased bleeding and possible hemorrhage. ■ Safety and effectiveness for use in pediatric patients younger than 4 years of age not established.

Elderly:

Imiglucerase: Specific information not available in product information.

Velaglucerase alfa:

Differences in responses and side effects between elderly and younger patients not identified; see Dose Adjustments.

DRUG/LAB INTERACTIONS

None indicated. Specific information not available.

SIDE EFFECTS

Imiglucerase:

Headache, hypersensitivity reactions, pruritus, and rash were most commonly reported. In addition, abdominal discomfort; backache; burning, discomfort, and pruritus at injection site; chills; diarrhea; dizziness; fatigue; fever; hypotension (mild); nausea; peripheral edema (transient); swelling or sterile abscess at venipuncture site; tachycardia; and vomiting were reported.

Pediatric patients 2 to 12 years:

Coughing, dyspnea, fever, flushing, nausea, and vomiting were most commonly reported in this age-group.

Velaglucerase alfa:

Abdominal pain, back pain, dizziness, fatigue/asthenia, fever, headache, hypersensitivity reactions, joint pain, nausea, and prolonged activated PTT were the most commonly reported adverse reactions and occurred more frequently in patients naïve to enzyme replacement therapy. Other reported side effects include bone pain, flushing, hypertension, hypotension, rash, tachycardia, urticaria, and vomiting.

Pediatric patients:

Adverse reactions similar to adults; however, fever, prolonged aPTT, and rash were seen more commonly in pediatric patients.

Both preparations:

A protein immune reaction may develop. Side effects may improve with continued therapy because antibody levels decrease. Hypersensitivity reactions (e.g., anaphylaxis, angioedema, chest discomfort, cyanosis, dyspnea, flushing, hypotension, pruritus, rash, respiratory symptoms, urticaria) have occurred.

ANTIDOTE

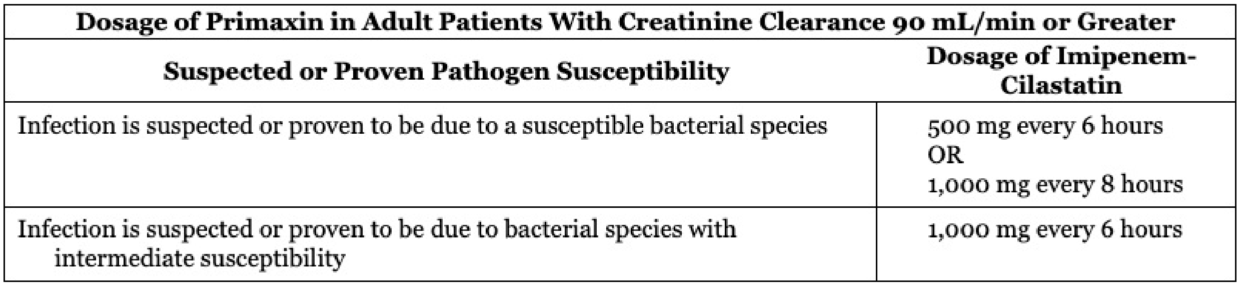
Keep physician informed of side effects; may be treated symptomatically if indicated. Based on the severity of the reaction, temporarily interrupt or discontinue infusion for clinical evidence of hypersensitivity reaction. Patients have successfully continued therapy after mild hypersensitivity or infusion reactions with pretreatment with antipyretics, antihistamines (e.g., diphenhydramine), and/or corticosteroids (e.g., dexamethasone) and/or a reduction in rate of administration. Treat anaphylaxis as necessary.

IMIPENEM-CILASTATIN

(em-ee-**PEN**-em sigh-lah-**STAT**-in)
Primaxin
Antibacterial (carbapenem)
pH 6.5 to 8.5

USUAL DOSE

Range is from 500 mg to 1 Gm every 6 to 8 hours. The maximum total daily dosage should not exceed 4 Gm/day. Dosage is based on susceptibility of pathogens and CrCl. The dosage recommendations in the following chart represent the quantity of imipenem to be administered. An equivalent amount of cilastatin is also present in the solution.



Dosage of Primaxin in Adult Patients With Creatinine Clearance 90 mL/min or Greater	
Suspected or Proven Pathogen Susceptibility	**Dosage of Imipenem-Cilastatin**
Infection is suspected or proven to be due to a susceptible bacterial species	500 mg every 6 hours OR 1,000 mg every 8 hours
Infection is suspected or proven to be due to bacterial species with intermediate susceptibility	1,000 mg every 6 hours

PEDIATRIC DOSE

Not recommended for use in pediatric patients with CNS infections because of the risk of seizures, or in pediatric patients weighing less than 30 kg with impaired renal function (no data available). Do not exceed 4 Gm/24 hr.

Infants 3 months of age or less, weighing 1,500 Gm or more: For non-CNS infections:

Less than 1 week of age: 25 mg/kg every 12 hours.
1 to 4 weeks of age: 25 mg/kg every 8 hours.
4 weeks to 3 months of age: 25 mg/kg every 6 hours.

Infants and other pediatric patients over 3 months of age: For non-CNS infections:

15 to 25 mg/kg/dose every 6 hours. See statements in Usual Dose.

Cystic fibrosis and normal renal function:

Higher doses up to 100 mg/kg/day have been used. Do not exceed 4 Gm/24 hr.

DOSE ADJUSTMENTS

Dose adjustments are required in adult patients with a CrCl less than 90 mL/min as shown in the following chart.

Dosage of Imipenem-Cilastatin for Adult Patients in Various Renal Function Groups Based on Estimated Creatinine Clearance (CrCl)				
	Creatinine Clearance (mL/min)			
	≥90 mL/min	≥60 to <90 mL/min	≥30 to <60 mL/min	≥15 to <30 mL/min
Infection is suspected or proven to be due to a susceptible bacterial species	500 mg every 6 hours	400 mg every 6 hours	300 mg every 6 hours	200 mg every 6 hours
	OR			
	1,000 mg every 8 hours	500 mg every 6 hours	500 mg every 8 hours	500 mg every 12 hours
Infection is suspected or proven to be due to a bacterial species with intermediate susceptibility	1,000 mg every 6 hours	750 mg every 8 hours	500 mg every 6 hours	500 mg every 12 hours

■ Patients with a CrCl of 15 to less than 30 mL/min may be at increased risk for seizures. ■ Patients with a CrCl less than 15 mL/min should not receive imipenem-cilastatin unless hemodialysis is instituted within 48 hours. ■ For patients with a CrCl less than 15 mL/min who are undergoing dialysis, administer the dose listed for patients with a CrCl of 15 to less than 30 mL/min. Cleared by hemodialysis; administer after hemodialysis. ■ Reduced doses may be required in elderly patients based on decreased renal function. ■ See Precautions/Monitor and Drug/Lab Interactions.

DILUTION

Reconstitute each vial with 10 mL of **compatible** infusion solutions (e.g., D5W, NS, D5NS, D5/½NS, D5/¼NS). Color of reconstituted solution ranges from colorless to yellow. Shake well and transfer the resulting suspension to 100 mL of the same infusion solution. Rinse vial with an additional 10 mL of infusion solution to ensure complete transfer of vial contents to the infusion solution. Agitate until clear.

Neonatal dilution:

Use preservative-free solutions for reconstitution of neonatal doses.

Filters:

Manufacturer's data limited; indicates that use of a filter system when withdrawing the suspension from the vial would probably result in filter clogging and decrease the available antibiotic. An in-house study documented **compatibility** of the final diluted solution with a 0.22-micron in-line filter.

Storage:

Store dry powder below 25° C (77° F). Diluted solutions are stable at room temperature for 4 hours after preparation or 24 hours if refrigerated. Do not freeze.

COMPATIBILITY

Manufacturer states, "Do not mix with or physically add to other antibiotics." See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent IV:

Each 500 mg or fraction thereof over 20 to 30 minutes. Doses greater than 500 mg should be infused over 40 to 60 minutes. Slow infusion rate if patient develops nausea. May be given through Y-tube or three-way stopcock of infusion set.

ACTIONS

A potent broad-spectrum antibacterial agent. Imipenem is a carbapenem antibiotic; cilastatin inhibits the kidney enzyme responsible for the metabolism of imipenem. Both components are present in equal amounts. Bactericidal to many gram-negative, gram-positive, and anaerobic organisms. Bactericidal activity results from the inhibition of bacterial wall synthesis. Effective against many otherwise resistant organisms. Has a high degree of stability in the presence of beta-lactamases produced by gram-negative and gram-positive bacteria. Rapidly and widely distributed into many body fluids and tissues. Metabolized in the kidneys. Half-life is approximately 1 hour. Excreted in the urine. May cross the placental barrier.

INDICATIONS AND USES

Treatment of the following serious infections caused by designated susceptible bacteria: lower respiratory tract, urinary tract (complicated and uncomplicated), skin and skin structure, bone and joint, gynecologic, and intra-abdominal infections; bacterial septicemia; and endocarditis.

Limitation of use:

Not indicated in patients with meningitis; safety and efficacy have not been established. ■ Not recommended in pediatric patients with CNS infections because of the risk of seizures. ■ Not recommended in pediatric patients under 30 kg with impaired renal function; data not available.

Unlabeled uses:

Treatment of cystic fibrosis exacerbations, febrile neutropenia, and melioidosis (a rare infection in humans and animals).

CONTRAINDICATIONS

Known sensitivity to any component of this product. ■ See Maternal/Child and Precautions.

PRECAUTIONS

Specific sensitivity studies are indicated to determine susceptibility of the causative organism to imipenem-cilastatin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, imipenem-cilastatin should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams (e.g., carbapenems, cephalosporins, penicillins). More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history. Cross-sensitivity is possible. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ CNS adverse effects, including confusional states, myoclonic activity, and seizures, have been reported. Incidence increases with higher doses, compromised renal function, or pre-existing CNS disorders. ■ For patients on hemodialysis, especially those with underlying CNS disease, benefits of use must outweigh risk of seizures. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with imipenem-cilastatin. ■ See Maternal/Child and Drug/Lab Interactions.

Monitor:

May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Electrolyte imbalance and cardiac irregularities resulting from sodium content are possible. Contains 3.2 mEq of sodium/Gm. ■ Monitor renal, hepatic, and hemopoietic systems in prolonged therapy. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking imipenem. ■ Promptly report S/S of hypersensitivity reactions. ■ See Drug/Lab Interactions.

Maternal/Child:

Data from a small number of post-marketing cases with use in pregnancy are not sufficient to identify any drug-associated risks for major birth defects, miscarriage, or adverse maternal/fetal outcomes. ■ Insufficient data on the presence of imipenem/cilastatin in human milk, and no data on the effects on the breast-fed child or on the effects on milk production.

Elderly:

Response similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out. ■ Consider age-related renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** concentrations to subtherapeutic levels, resulting in loss of seizure control. Increasing the dose of valproic acid may not be sufficient to overcome this interaction. Concomitant use of imipenem and **valproic acid/divalproex sodium** is generally not recommended. Consider alternative antibacterial therapy. If administration of imipenem is necessary, supplemental anticonvulsant therapy should be considered. ■ May be used concomitantly with **aminoglycosides and other antibiotics,** but these drugs must never be mixed in the same infusion or given concurrently. ■ Use with **ganciclovir** may cause generalized seizures. Use only if benefit outweighs risk. ■ Half-life and plasma levels slightly increased by **probenecid.** Avoid concurrent use. ■ **Cyclosporine** may enhance the neurotoxic effect of imipenem. Imipenem may increase or decrease the serum concentration of cyclosporine.

SIDE EFFECTS

Adults:

The most frequently occurring adverse reactions are diarrhea, dizziness, erythema or pain at injection site, fever, hypotension, nausea, phlebitis, pruritus, rash, seizures, somnolence, urticaria, vein induration, and vomiting.

Pediatric patients 3 months of age or older:

The most frequently reported adverse reactions include diarrhea, gastroenteritis, IV site irritation, phlebitis, rash, urine discoloration, and vomiting.

Neonates:

Convulsions, diarrhea, oliguria/anuria, oral candidiasis, rash, and tachycardia are the most frequently reported adverse reactions.

Reported serious adverse reactions include CDAD, seizures, and a full scope of hypersensitivity reactions, including anaphylaxis, pruritus, rash, and urticaria. Several other reactions have been reported in fewer than 0.2% of patients.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Resuscitate as necessary. Begin anticonvulsants if focal tremors, myoclonus, or seizures occur. If symptoms continue, decrease dose or discontinue the drug. Infusion rate reactions may respond to a decrease in rate of infusion. Mild cases of CDAD may respond to discontinuation of the drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Both imipenem and cilastatin are removed by hemodialysis. Hemodialysis may be useful in overdose.

IMIPENEM, CILASTATIN, AND RELEBACTAM

(**IM**-i-**PEN**-em, **SYE**-la-**STAT**-in, and **REL**-e-**BAK**-tam)
Recarbrio
Antibacterial (carbapenem, beta-lactamase inhibitor)
pH 6.5 to 7.6

USUAL DOSE

Pretreatment:

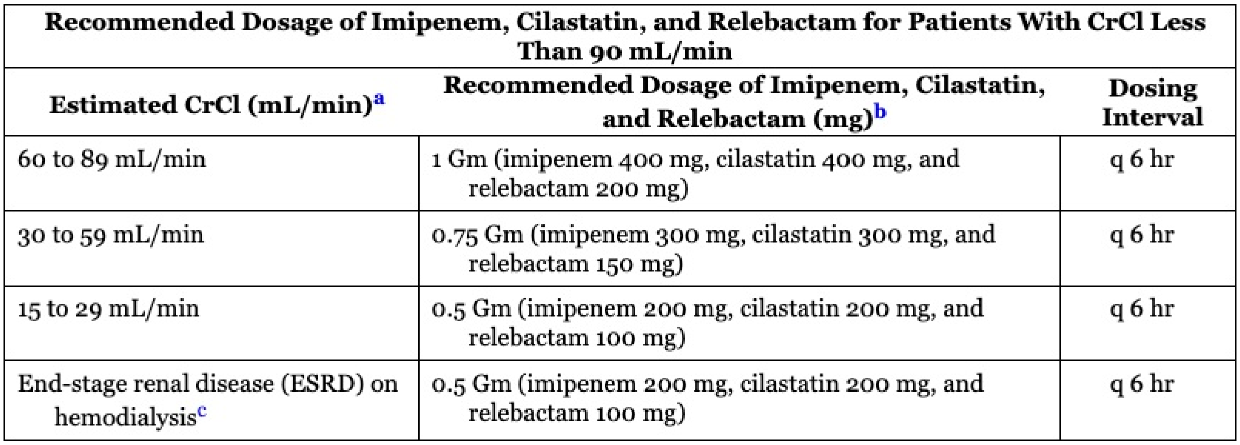
Baseline studies indicated; see Monitor.

Imipenem, cilastatin, and relebactam:

1.25 Gm (imipenem 500 mg, cilastatin 500 mg, relebactam 250 mg) every 6 hours as an IV infusion over 30 minutes. Duration of therapy is 4 to 14 days. Duration guided by the severity and location of infection and the patient's clinical response.

DOSE ADJUSTMENTS

Adjust dose in patients with CrCl less than 90 mL/min as outlined in the following chart.



Recommended Dosage of Imipenem, Cilastatin, and Relebactam for Patients With CrCl Less Than 90 mL/min

Estimated CrCl (mL/min)[a]	Recommended Dosage of Imipenem, Cilastatin, and Relebactam (mg)[b]	Dosing Interval
60 to 89 mL/min	1 Gm (imipenem 400 mg, cilastatin 400 mg, and relebactam 200 mg)	q 6 hr
30 to 59 mL/min	0.75 Gm (imipenem 300 mg, cilastatin 300 mg, and relebactam 150 mg)	q 6 hr
15 to 29 mL/min	0.5 Gm (imipenem 200 mg, cilastatin 200 mg, and relebactam 100 mg)	q 6 hr
End-stage renal disease (ESRD) on hemodialysis[c]	0.5 Gm (imipenem 200 mg, cilastatin 200 mg, and relebactam 100 mg)	q 6 hr

[a] CrCl calculated using the Cockroft-Gault formula.

[b] Administer by IV over 30 minutes.

[c] Administration should be timed to follow hemodialysis.

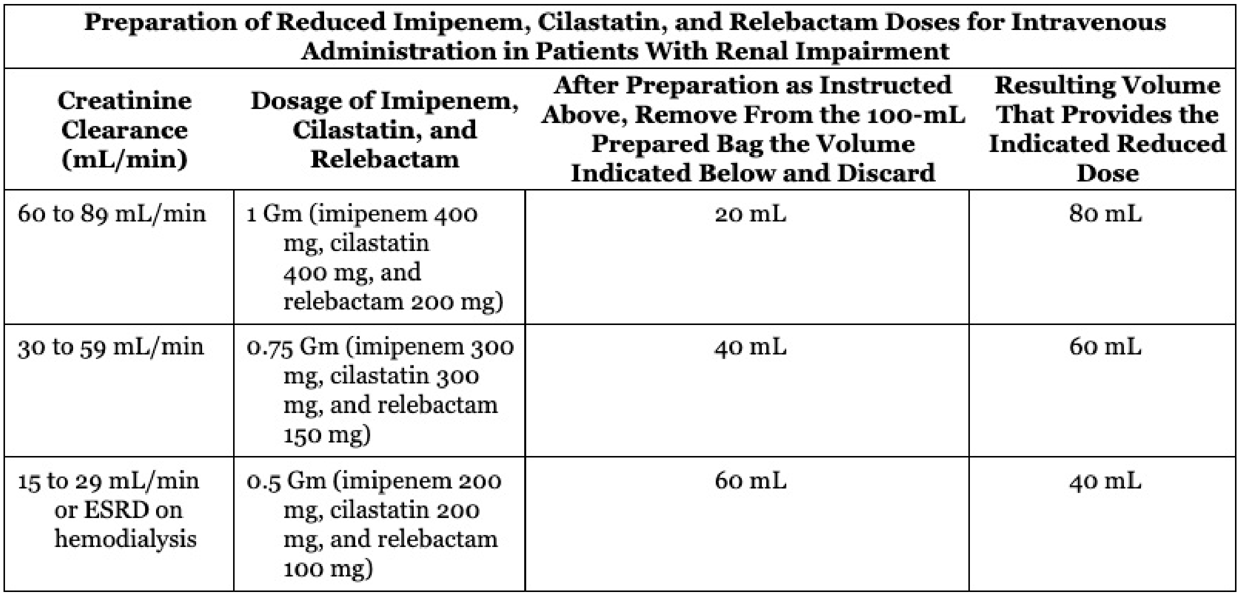
■ Patients with a CrCl less than 15 mL/min should not receive imipenem, cilastatin, and relebactam unless hemodialysis is instituted within 48 hours. ■ There is inadequate information to recommend usage of imipenem, cilastatin, and relebactam in patients undergoing peritoneal dialysis. ■ Imipenem, cilastatin, and relebactam is removed from the circulation by hemodialysis. In hemodialysis patients, administer after hemodialysis and at intervals timed from the end of the dialysis session. ■ Reduced dose may be indicated in elderly patients; consider age-related impaired renal function and concomitant disease states. ■ No clinically significant differences in pharmacokinetics of imipenem, cilastatin, and relebactam were observed based on age, gender, or race.

DILUTION

Supplied as a dry white to light yellow sterile powder for reconstitution. Each single-dose vial contains 1.25 Gm (imipenem 500 mg, cilastatin 500 mg, and relebactam 250 mg). May be reconstituted and diluted with NS, D5W, D5NS, D5/½NS, or D5/¼NS. Imipenem, cilastatin, and relebactam has low aqueous solubility. To ensure complete dissolution, adhere to the following preparation instructions:

Step 1. For diluents available in 100-mL prefilled infusion bags, proceed to Step 2. For diluents not available in 100-mL prefilled infusion bags, withdraw 100 mL of the desired diluent and transfer it to an empty infusion bag, then proceed to Step 2.
Step 2. Withdraw 20 mL (as two 10-mL aliquots) of diluent from the appropriate infusion bag and reconstitute the vial with one 10-mL aliquot of the diluent. The reconstituted suspension must be further diluted.
Step 3. After reconstitution, shake vial well and transfer resulting suspension into the remaining 80 mL of the infusion bag.
Step 4. Add the second 10-mL aliquot of infusion diluent to the vial and shake well to ensure complete transfer of vial contents; repeat transfer of the resulting suspension to the infusion solution before administering. Agitate the resulting mixture until clear. Diluted solution color ranges from colorless to yellow.

For patients with renal impairment, prepare a reduced dose of imipenem, cilastatin, and relebactam by preparing a 100-mL solution containing 1.25 Gm and then withdrawing and discarding the excess volume as described in the following chart.



Preparation of Reduced Imipenem, Cilastatin, and Relebactam Doses for Intravenous Administration in Patients With Renal Impairment

Creatinine Clearance (mL/min)	Dosage of Imipenem, Cilastatin, and Relebactam	After Preparation as Instructed Above, Remove From the 100-mL Prepared Bag the Volume Indicated Below and Discard	Resulting Volume That Provides the Indicated Reduced Dose
60 to 89 mL/min	1 Gm (imipenem 400 mg, cilastatin 400 mg, and relebactam 200 mg)	20 mL	80 mL
30 to 59 mL/min	0.75 Gm (imipenem 300 mg, cilastatin 300 mg, and relebactam 150 mg)	40 mL	60 mL
15 to 29 mL/min or ESRD on hemodialysis	0.5 Gm (imipenem 200 mg, cilastatin 200 mg, and relebactam 100 mg)	60 mL	40 mL

Filter:

Data not available.

Storage:

Store unopened vial in original carton at CRT. Infusion bag maintains satisfactory potency for at least 2 hours at RT (up to 30° C [86° F]) or for at least 24 hours under refrigeration at 2° to 8° C (36° to 46° F). ***Do not freeze.*** Discard any unused solution from the infusion bag.

COMPATIBILITY

The manufacturer states, "**Incompatible** with propofol in 5% Dextrose USP or 0.9% Sodium Chloride USP." No other **compatibility** information provided; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes.

ACTIONS

An antibacterial combination product consisting of imipenem (a carbapenem antibacterial drug), cilastatin (a renal dehydropeptidase inhibitor), and relebactam (a diazabicyclooctane beta lactamase inhibitor). The bactericidal activity of imipenem results from binding to PBP 2 and PBP1 B in Enterobacteriaceae and *Pseudomonas aeruginosa* and the subsequent inhibition of penicillin binding proteins (PBPs). Inhibition of PBPs leads to the disruption of bacterial cell wall synthesis. Cilastatin and relebactam do not have antibacterial activity. When administered alone, imipenem is metabolized in the kidneys by dehydropeptidase. Cilastatin, an inhibitor of this enzyme, effectively prevents renal metabolism of imipenem. Relebactam protects imipenem from degradation by certain serine beta lactamases. Protein binding is approximately 20% for imipenem, 40% for cilastatin, and 22% for relebactam. Relebactam is minimally metabolized. All three components are excreted by the kidneys. The half-lives for imipenem and relebactam are 1 hour and 1.2 hours, respectively.

INDICATIONS AND USES

Treatment of complicated urinary tract infections (cUTIs), including pyelonephritis, caused by susceptible gram-negative microorganisms (*Enterobacter cloacae, Escherichia coli, Klebsiella aerogenes, Klebsiella pneumoniae,* and *Pseudomonas aeruginosa*) in patients 18 years of age or older who have limited or no alternative treatment options. ■ Treatment of complicated intra-abdominal infections (cIAIs) caused by susceptible gram-negative microorganisms (*Bacteroides caccae, Bacteroides fragilis, Bacteroides ovatus, Bacteroides stercoris, Bacteroides thetaiotaomicron, Bacteroides uniformis, Bacteroides vulgatus, Citrobacter freundii, Enterobacter cloacae, Escherichia coli, Fusobacterium nucleatum, Klebsiella aerogenes, Klebsiella oxytoca, Klebsiella pneumoniae, Parabacteroides distasonis,* and *Pseudomonas aeruginosa*) in patients 18 years of age or older who have limited or no alternative treatment options.

Approval of these indications is based on limited clinical safety and efficacy data.

CONTRAINDICATIONS

History of known severe hypersensitivity (severe systemic allergic reaction, such as anaphylaxis) to any component of imipenem, cilastatin, and relebactam.

PRECAUTIONS

Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients receiving beta-lactam antibacterial drugs. Check history of previous hypersensitivity reactions to other carbapenems, penicillins, cephalosporins, other beta lactams, and other allergens. Cross-sensitivity among beta-lactam antibacterial drugs has been established. ■ Specific sensitivity studies indicated to determine susceptibility of causative organism to imipenem, cilastatin, and relebactam. ■ Cross-resistance with other classes of antibacterial drugs has not been identified; therefore isolates resistant to other carbapenems, including imipenem, and to cephalosporins may be susceptible to imipenem, cilastatin, and relebactam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, imipenem, cilastatin, and relebactam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ CNS adverse reactions, such as seizures, confusional states, and myoclonic activity, have been reported during treatment with imipenem/cilastatin (a component of imipenem, cilastatin, and relebactam), especially when recommended dosages of imipenem were exceeded. These have been reported most commonly in patients with CNS disorders (e.g., brain lesions or history of seizures) and/or compromised renal function; see Dose Adjustments. Anticonvulsant therapy should be continued in patients with known seizure disorders. ■ Concomitant use of imipenem, cilastatin, and relebactam with valproic acid or divalproex sodium may increase the risk of breakthrough seizures; see Drug/Lab Interactions. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with imipenem, cilastatin, and relebactam.

Monitor:

Obtain baseline and periodic CBC and SCr. ■ Monitor CrCl in patients with fluctuating renal function and adjust dosage accordingly; see Dose Adjustments. ■ Monitor for S/S of a hypersensitivity reaction. ■ Monitor for S/S of CNS adverse reactions. If CNS adverse reactions (including seizures) occur, patients should undergo a neurologic evaluation to determine whether imipenem, cilastatin, and relebactam should be discontinued.

Patient Education:

Review list of allergies, medications, and medical conditions with provider. ■ Promptly report any symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash) or neurologic symptoms (e.g., confusion, myoclonus, seizures). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Safety for use during pregnancy and breast-feeding have not been established; use caution. ■ Safety and efficacy for use in pediatric patients younger than 18 years of age have not been established.

Elderly:

Consider age-related renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Generalized seizures have been reported in patients who received **ganciclovir** concomitantly with imipenem/cilastatin (components of imipenem, cilastatin, and relebactam). Avoid concomitant administration unless the potential benefits outweigh the risks. ■ Concomitant use of carbapenems, including imipenem/cilastatin (components of imipenem, cilastatin, and relebactam), with **valproic acid** or **divalproex sodium** may decrease valproic acid concentrations, which may increase the risk of breakthrough seizures. Avoid concomitant use with valproic acid or divalproex sodium. Consider alternative antibacterials other than carbapenems to treat infections in patients whose seizures are well controlled with valproic acid or divalproex sodium. ■ No clinically significant differences in the pharmacokinetics of imipenem or relebactam were observed when imipenem, cilastatin, and relebactam was used concomitantly with **probenecid**. ■ In vitro studies have demonstrated no antagonism between imipenem/relebactam and **amikacin, azithromycin, aztreonam, colistin, gentamicin, levofloxacin, linezolid, tigecycline, tobramycin,** or **vancomycin**.

SIDE EFFECTS

The most common adverse reactions include diarrhea, elevations in AST and ALT, fever, headache, hypertension, nausea, phlebitis/infusion site reactions, and vomiting. Other reported reactions included anemia, CDAD, CNS adverse reactions (agitation, apathy, confusional states, delirium, disorientation, slow speech, and somnolence), and increased lipase and serum creatinine.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reaction as indicated. If CNS adverse reactions (including seizures) occur, patients should undergo a neurologic evaluation to determine whether imipenem, cilastatin, and relebactam should be discontinued. Mild cases of CDAD may respond to discontinuation of imipenem, cilastatin, and relebactam. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Imipenem, cilastatin, and relebactam is removed by hemodialysis.

IMMUNE GLOBULIN INTRAVENOUS BBW

(im-**MUNE GLAW**-byoo-lin IV)

Bivigam, Carimune NF, Flebogamma, Gammagard Liquid, Gammagard S/D, Gammaked, Gammaplex, Gamunex-C, IGIV, Octagam, Panzyga (IGIV-ifas), Privigen

Immunizing agent (passive)

pH 4 to 7.2

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

For all indications, ensure adequate hydration before administration.

Primary Immunodeficiency (PID) Diseases

Bivigam and Gammuplex:

300 to 800 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Monitor clinical response and trough levels to adjust dose as appropriate. Desired trough level of total IgG concentrations is a minimum of 500 mg/dL (target is 600 mg/dL).

Carimune NF:

400 to 800 mg/kg as a single-dose IV infusion. Administer once every 3 to 4 weeks. Use of a 3% solution is recommended for the first infusion in previously untreated agammaglobulinemic or hypogammaglobulinemic patients. Subsequent infusions may be administered at a higher concentration based on patient tolerance.

Flebogamma, Gammagard Liquid, Gammagard S/D, Gammaked, Gamunex-C, Octagam 5%, and Panzyga:

300 to 600 mg/kg as a single-dose IV infusion every 3 to 4 weeks. Individualize dose and interval based on clinical response. If a patient receiving ***Gammaked, Gamunex-C,*** or ***Octagam*** is routinely receiving a dose of less than 400 mg/kg and is at risk for measles exposure (i.e., traveling to a measles endemic area), administer a dose of at least 400 mg/kg just before the expected measles exposure. If a patient is exposed to measles, administer a dose of 400 mg/kg as soon as possible after exposure.

Privigen:

200 to 800 mg/kg (2 to 8 mL/kg) as a single-dose IV infusion every 3 to 4 weeks. Adjust dose to achieve desired serum trough levels and clinical response.

Idiopathic Thrombocytopenic Purpura (ITP)

All products must be given by IV infusion for ITP patients. Do not administer SC due to a potential risk of hematoma.

Carimune NF:

400 mg/kg/day for 2 to 5 consecutive days based on platelet count and clinical response. A 6% solution is recommended for use in ITP. May be discontinued in acute ITP of childhood if an initial platelet count response to the first 2 doses is adequate (30,000 to 50,000/mm^3). After induction, if clinically significant bleeding occurs and/or the platelet count falls below 30,000/mm^3, a maintenance dose of 400 mg/kg may be given as a single infusion. If response inadequate, increase to 800 to 1,000 mg/kg. May be given intermittently to maintain platelet count.

Flebogamma 10%:

1 Gm/kg/day for 2 consecutive days.

Gammagard S/D:

1 Gm/kg. Up to 3 doses can be given on alternate days based on clinical response and platelet count.

Gammaked and Gamunex-C:

1 Gm/kg/day (10 mL/kg/day) for 2 consecutive days for a total dose of 2 Gm/kg. May withhold the second 1 Gm/kg dose if an adequate platelet response is seen within 24 hours. Alternately, the 2 Gm/kg total dose can be administered as 400 mg/kg/day (4 mL/kg/day) for 5 consecutive days. The high-dose regimen (1 Gm/kg/day for 1 to 2 days) is not recommended for individuals with expanded fluid volumes or when fluid volume may be a concern.

Gammaplex, Octagam 10%, Privigen, and Panzyga:

Chronic ITP:

1 Gm/kg/day for 2 consecutive days for a total dose of 2 Gm/kg.

B-Cell Chronic Lymphocytic Leukemia (CLL)

Gammagard S/D:

400 mg/kg every 3 to 4 weeks.

Chronic Inflammatory Demyelinating Polyneuropathy (CIDP)

Gamunex-C and Gammaked: Loading dose:

1 Gm/kg/day (10 mL/kg/day) for 2 consecutive days or 0.5 Gm/kg/day (5 mL/kg/day) for 4 consecutive days. With either regimen the total dose is 2 Gm/kg. Follow with ***maintenance dose*** of 1 Gm/kg every 3 weeks. The maintenance dose may be given as a total dose of 1 Gm/kg (10 mL/kg) on Day 1 or divided into 2 doses of 500 mg/kg/day given over 2 consecutive days.

Privigen: Loading dose:

2 Gm/kg (20 mL/kg) in divided doses over 2 to 5 consecutive days. Administer a ***maintenance dose*** of 1 Gm/kg (10 mL/kg) in 1 to 2 infusions on consecutive days every 3 weeks.

Multifocal Motor Neuropathy (MMN)

Gammagard Liquid:

Dose range is 0.5 to 2.4 Gm/kg/month based on clinical response.

PEDIATRIC DOSE

Kawasaki Syndrome

Gammagard S/D:

A single dose of 1 Gm/kg as an IV infusion. Alternately, 400 mg/kg/day may be administered for 4 consecutive days. Begin within 7 days of onset of fever. Concomitant administration of aspirin 80 to 100 mg/kg/day in 4 divided doses is indicated.

Other Indications

See specific product manufacturer prescribing information for age restrictions for other indications.

See mg/kg or Gm/kg dose recommendations under Usual Dose. Begin with the lowest recommended dose. With most brands, clinical studies suggested that no difference in dosing is necessary and no special precautions are indicated. According to the manufacturers, infants and neonates were not included in clinical studies for primary immunodeficiency diseases or Kawasaki disease. All age-groups were represented in clinical studies for idiopathic thrombocytopenic purpura. See Maternal/Child.

DOSE ADJUSTMENTS

Adjust dose according to IgG levels and clinical response. Frequency and dose will vary from patient to patient. No controlled clinical trials are available to determine optimum trough serum IgG level.

DILUTION

Requirements for dilution of liquid and lyophilized powder preparations are brand specific and vary considerably; see manufacturer's package insert. Some may be further diluted only with D5W or with D5W and/or NS; others cannot be diluted. Some require D5W or NS to flush the infusion line.

All formulations:

Do not mix with IGIV products from other manufacturers. Do not mix with other medicinal products. Administer through a separate infusion line or flush line before and after administration. Do not use if solution is cloudy, turbid, or contains particulate matter. Do not freeze. Do not use if previously frozen. Do not use beyond expiration date. For single use only; use promptly or discard unused product. Bring to room temperature before reconstitution (if required) or administration.

Most formulations:

Do not shake. If large doses are to be administered, several vials may be pooled using aseptic technique (time limits or specific processes may apply); see specific product.
Bivigam, Flebogamma, Gamunex-C, Gammagard Liquid, Gammaked, Gammaplex, Octagam, Panzyga, and ***Privigen*** are liquid preparations and are ready to use.
Carimune NF is a lyophilized product, ***and Gammagard S/D*** is a freeze-dried product. Both require reconstitution. Absolute sterile technique is required at all steps of the reconstitution process. Filtration may be required as drawn into a syringe for administration or as administered through IV tubing. Check both brands for specific equipment and specific dilution requirements.

Bivigam:

A ready-to-use 10% sterile solution; do not dilute. Available as 5 Gm in 50 mL or 10 Gm in 100 mL. Does not contain sucrose. Warm to room temperature before use and maintain at room temperature during administration. ***Do not shake.*** Several vials may be pooled using aseptic technique into sterile infusion bags and infused. pH 4 to 4.6.

Carimune NF:

Contains sucrose; see Precautions. Available as a lyophilized powder in 3-, 6-, and 12-Gm vials. Reconstitute with NS, D5W, or SWFI. Package insert has a chart with dilution requirements for all concentrations. ***Do not shake.*** Immediate use is recommended unless reconstituted under a sterile laminar flow hood; then it may be refrigerated and administration must begin within 24 hours. Several reconstituted vials of identical concentration and diluent may be pooled in an empty sterile glass or plastic IV infusion container using aseptic technique. pH 6.4 to 6.8. A 6% solution of ***Carimune NF*** is recommended for use in ITP.

Flebogamma:

Contains sorbitol; does not contain sucrose. A ready-to-use 5% (50 mg/mL)sterile solution; available as 0.5 Gm in 10 mL, 2.5 Gm in 50 mL, 5 Gm in 100 mL, 10 Gm in 200 mL, and 20 Gm in 400 mL. Also available as a ready-to-use 10% (100 mg/mL) sterile solution of 5 Gm in 50 mL, 10 Gm in 100 mL, and 20 Gm in 200 mL concentrations. Further dilution with other solutions not recommended. Using aseptic technique, several vials may be pooled into an empty sterile solution container. See Filters. pH 5 to 6.

Gammagard Liquid:

Does not contain sucrose. A ready-to-use 10% solution available as 1 Gm in 10 mL, 2.5 Gm in 25 mL, 5 Gm in 50 mL, 10 Gm in 100 mL, and 20 Gm in 200 mL. Warm to room temperature before use. ***Do not shake.*** May be further diluted only with D5W. See Filters. pH 4.6 to 5.1.

Gammagard S/D:

Does not contain sucrose. A freeze-dried preparation. Must be warmed to room temperature before reconstitution if refrigerated. Diluent (SWFI), transfer device, administration set with integral airway, and filter provided with each single-use vial. Available in 2.5-, 5-, and 10-Gm single-dose vials with diluent. Use full amount of diluent (50, 96, 192 mL) to prepare a 5% solution (50 mg/mL), or remove one-half the amount of diluent (25, 48, 96 mL) to prepare a 10% solution (100 mg/mL). ***Do not shake.*** Must be used within 2 hours of dilution if prepared outside a laminar flow hood. Administer within 24 hours if prepared aseptically inside a sterile laminar flow hood and stored in the original glass container or pooled into ViaFlex bags under constant refrigeration. Record date and time of reconstitution/pooling. pH 6.4 to 7.2.

Gammaked:

Does not contain sucrose. A ready-to-use 10% solution. Available as 1 Gm in 10 mL, 2.5 Gm in 25 mL, 5 Gm in 50 mL, 10 Gm in 100 mL, and 20 Gm in 200 mL. Bring to room temperature before administration if refrigerated. Use an 18-gauge needle or dispensing pin to penetrate the stopper of the 10-mL vial. Use 16-gauge needles or dispensing pins for the 25 mL and larger sizes. May be further diluted with D5W if required. Do not use any other diluent. ***Do not shake.*** Content of vials may be pooled under aseptic conditions into sterile infusion bags but must be infused within 8 hours of pooling. pH is 4 to 4.5.

Gammaplex:

Does not contain sucrose but does contain fructose; see Contraindications. A ready-to-use 5% sterile solution. Available as 2.5 Gm in 50 mL, 5 Gm in 100 mL, and 10 Gm in 200 mL. ***Do not shake.*** Begin infusion within 2 hours if multiple vials are pooled under aseptic conditions. Bring to room temperature before administration if refrigerated. pH 4.8 to 5.1.

Gamunex-C:

Does not contain sucrose. A ready-to-use 10% sterile solution. Available in 1-, 2.5-, 5-, 10-, and 20-Gm single-dose vials. Bring to room temperature before administration if refrigerated. Use an 18-gauge needle to penetrate the stopper of the 1-Gm size. Use a 16-gauge needle to penetrate the stopper of the 2.5- to 20-Gm sizes. Penetration of the stopper in the center of the raised ring and perpendicular to it is recommended. May be further diluted with D5W if required. Do not use any other diluent. Filtration during administration is not required. Use within 8 hours if multiple vials are pooled under aseptic conditions. pH 4 to 4.5.

Octagam:

Does not contain sucrose but does contain maltose; see Contraindications. A ready-to-use 5% or 10% sterile solution. The 5% solution is available as 1-, 2.5-, 5-, 10-, and 25-Gm single-dose vials. The 10% solution is available as 2- 5-, 10-, and 20-Gm single-dose vials. ***Do not shake.*** Use within 8 hours if multiple vials are pooled under aseptic conditions. Bring to room temperature before administration if refrigerated. pH 5.1 to 6 (5%); pH 4.5 to 5 (10%).

Panzyga:

Does not contain sucrose. A ready-to-use 10% sterile solution. Available in 1-, 2.5-, 5-, 10-, 20-, and 30-Gm single-dose vials. Use within 8 hours if multiple vials are pooled under aseptic conditions. pH 4.5 to 5.

Privigen:

Does not contain sucrose but does contain l-proline; see Contraindications. A ready-to-use 10% sterile solution. Available in 5-, 10-, 20-, and 40-Gm single-dose vials. ***Do not shake.*** May be further diluted with D5W if required. Do not use any other diluent. Filtration during administration is not required. Content of vials may be pooled under aseptic conditions into sterile infusion bags but infusion should begin within 8 hours of pooling; contains no preservatives. pH 4.6 to 5.

Filters:

Filter or filter needle is provided by most manufacturers. ***Carimune NF and Flebogamma*** may be filtered with a larger pore filter size but is not required by manufacturers (filters greater than or equal to 15 microns will be less likely to slow infusion [0.2-micron antibacterial filters may be used with ***Carimune NF, Flebogamma, and Octagam***]). ***Carimune NF*** is nano-filtered. Filtration of ***Gamunex-C*** during administration is not required; however, use of a non–protein-binding, 0.22-micron filter is permissible. Use of an in-line filter is optional with ***Gammagard Liquid and Octagam***. ***Panzyga*** does not require filtration; however, it may be filtered with a filter size of 0.2 to 200 microns.

Storage:

Storage requirements are brand specific and vary considerably from refrigeration only to continuous or partial storage at RT not exceeding 30° C (77° F); see manufacturer’s package insert. Do not use after expiration date. Discard partially used vials. Do not use if solution is turbid or has been frozen. Some specifically state, “Do not heat or microwave.”

COMPATIBILITY

Manufacturers recommend administration through a separate IV line without admixture with other drugs and state, “Do not combine one IGIV product with an IGIV product from another manufacturer.” ***Gammagard Liquid, Gammaked, Gamunex-C, and Privigen*** are **compatible** only with D5W and are **incompatible** with NS. ***Flebogamma and Octagam*** should not be further diluted with any solution.

Most preparations may be infused sequentially into a primary IV of D5W or NS, or the tubing may be flushed with D5W or NS before and after administration.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

All formulations:

Too-rapid infusion may cause a precipitous hypotensive reaction. Decrease rate of infusion at onset of patient discomfort or any adverse reactions; see Antidote. Decrease rate in patients at risk for neuromuscular disorders. See Precautions and individual products for suggested decrease in rates for patients at risk for thrombosis or developing renal dysfunction. Administer via separate IV tubing with filter or filter needle (provided by most manufacturers if required). Do not mix with IGIV products from other manufacturers or with other drugs or IV solutions. An infusion pump will facilitate an accurate rate of administration.

Bivigam:

Does not contain sucrose. 0.5 mg/kg/min for the first 10 minutes. If no discomfort or adverse effects, may be increased every 20 minutes by 0.8 mg/kg/min up to 6 mg/kg/min. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Carimune NF:

Contains sucrose; see Precautions. An initial infusion rate of 0.5 mg/kg/min for 30 minutes. May then be increased to 1 mg/kg/min for the next 30 minutes. May be gradually increased in steps up to a maximum of 3 mg/kg/min as tolerated. The first dose in previously untreated agammaglobulinemic or hypogammaglobulinemic patients must be a 3% solution. After the first dose, subsequent infusions may be administered at a higher concentration as tolerated; see Precautions. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose; the maximum rate of infusion should not exceed 2 mg/kg/min.

Flebogamma:

Does not contain sucrose. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency (PI):

Initiate 5% solution at 0.01 mL/kg/min (0.5 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.1 mL/kg/min (5 mg/kg/min).

Primary immunodeficiency (PI) and idiopathic thrombocytopenic purpura (ITP):

Initiate 10% solution at 0.01 mL/kg/min (1 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 0.08 mL/kg/min (8 mg/kg/min).

Gammagard Liquid:

Does not contain sucrose. In patients at risk for developing renal dysfunction or thrombotic episodes, the maximum infusion rate should be less than 3.3 mg/kg/min (less than 2 mL/kg/hr).

Primary immunodeficiency (PI):

0.5 mL/kg/hr (0.8 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased every 30 minutes to a maximum rate of 5 mL/kg/hr (8 mg/kg/min).

Multifocal motor neuropathy (MMN):

0.5 mL/kg/hr. (0.8 mg/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased every 30 minutes to a maximum rate of 5.4 mL/kg/hr (9 mg/kg/min).

Gammagard S/D:

Dose not contain sucrose. 5% solution 0.5 mL/kg/hr. May be gradually increased to a maximum rate of 4 mL/kg/hr if no discomfort or adverse effects. If 5% solution well tolerated at 4 mL/kg/hr, a 10% solution can be used. Begin with 0.5 mL/kg/hr. If no adverse effects, gradually increase up to a maximum of 8 mL/kg/hr. In patients at risk for developing renal dysfunction, the concentration and infusion rate should be less than 3.3 mg/kg/min (less than 2 mL/kg/hr of 10% or less than 4 mL/kg/hr of 5%).

Gammaked:

Does not contain sucrose. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency (PI) and idiopathic thrombocytopenic purpura (ITP):

1 mg/kg/min (0.01 mL/kg/min). If the infusion is well tolerated, the rate may be gradually increased to a maximum of 8 mg/kg/min (0.08 mL/kg/min).

Chronic inflammatory demyelinating polyneuropathy (CDIP):

2 mg/kg/min (0.02 mL/kg/min). If the infusion is well tolerated, the rate may be gradually increased to a maximum of 8 mg/kg/min (0.08 mL/kg/min).

Gammaplex:

Does not contain sucrose. 0.5 mg/kg/min (0.01 mL/kg/min) for the first 15 minutes. If no discomfort or adverse effects, may be gradually increased every 15 minutes to 4 mg/kg/min (0.08 mL/kg/min). In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Gamunex-C:

Does not contain sucrose. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency (PI) and idiopathic thrombocytopenic purpura (ITP):

1 mg/kg/min (0.01 mL/kg/min) for the first 30 minutes. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 8 mg/kg/min (0.08 mL/kg/min).

Chronic inflammatory demyelinating polyneuropathy (CIDP):

2 mg/kg/min (0.02 mL/kg/min). If no discomfort or adverse effects, may be gradually increased to a maximum rate of 8 mg/kg/min (0.08 mL/kg/min).

Octagam:

Does not contain sucrose; does contain maltose. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency (PI):

Initiate 5% solution at 0.5 mg/kg/min for the first 30 minutes. If no discomfort or adverse effects, may increase gradually in 30-minute increments to a maximum rate of 3.33 mg/kg/min.

Idiopathic thrombocytopenic purpura (ITP):

Initiate 10% solution at 1 mg/kg/min for the first 30 minutes. If no discomfort or adverse effects, may increase gradually in 30-minute increments to a maximum rate of 12 mg/kg/min.

Panzyga:

Does not contain sucrose. In patients at risk for thrombosis or for developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency (PI) and idiopathic thrombocytopenic purpura (ITP):

An initial infusion rate of 1 mg/kg/min (0.01 mL/kg/min) is recommended. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 8 mg/kg/min (0.08 mL/kg/min). In patients with ***primary immunodeficiency*** who have received 3 to 6 infusions, the rate may be increased to 12 or 14 mg/kg/min (0.12 or 0.14 mL/kg/min) as tolerated.

Privigen:

Does not contain sucrose. IV line may be flushed with D5W or NS. In patients at risk for thrombosis or developing renal dysfunction, administer at the minimum dose and rate of infusion that is practicable.

Primary immunodeficiency:

0.5 mg/kg/min (0.005 mL/kg/min) initially. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 8 mg/kg/min (0.08 mL/kg/min).

Chronic immune thrombocytopenic purpura:

0.5 mg/kg/min (0.005 mL/kg/min) initially. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 4 mg/kg/min (0.04 mL/kg/min).

Chronic inflammatory demyelinating polyneuropathy:

0.5 mg/kg/min (0.005 mL/mg/min) initially. If no discomfort or adverse effects, may be gradually increased to a maximum rate of 8 mg/kg/min (0.08 mL/kg/min).

ACTIONS

A preparation of concentrated human immunoglobulin G (IgG) antibodies. Obtained, purified, and standardized from human plasma. Specific methods during the manufacturing process (e.g., cold ethanol fractionation, detergents, solvents, nanofiltration) inactivate blood-borne viruses (e.g., hepatitis, HIV). Used as replacement therapy in primary and secondary immunodeficiencies. Active against bacterial, viral, parasitic, and mycoplasma antigens. Capable of both opsonization and neutralization of microbes and toxins.Also contains antibodies capable of interacting with and altering the activity of the immune system as well as antibodies capable of reacting with cells such as erythrocytes. (The role of these antibodies and the mechanisms of action of IgG have not been fully clarified.) Provides immediate antibody levels following infusion. The immediate peak in serum IgG is followed by a rapid decay due to equilibration between the plasma and extravascular fluid compartments. Half-life is variable (approximately 3 to 6 weeks) but may be decreased by fever or infection (increased catabolism or consumption). Crosses the placenta.

INDICATIONS AND USES

Selected products are approved for different uses; see Usual Dose. All provide rapid-onset, short-term passive immunization. Labeled uses include: ***Primary immunodeficiency diseases:*** Replacement therapy in adults, adolescents, and other pediatric patients unable to produce adequate amounts of IgG antibodies, especially in the following situations: need for immediate increase in intravascular immunoglobulin levels, small muscle mass or bleeding tendencies that contraindicate IM injection, and selected disease states (e.g., congenital agammaglobulinemia, common variable immunodeficiency [CVID], combined immunodeficiency, X-linked agammaglobulinemia, Wiskott-Aldrich syndrome). ■ ***Treatment of acute and chronic idiopathic thrombocytopenic purpura (also called immune thrombocytopenic purpura or primary immune thrombocytopenia):*** Temporary increase in platelet counts in patients with idiopathic thrombocytopenic purpura and with thrombocytopenia associated with bone marrow transplant. ■ ***Treatment of chronic inflammatory demyelinating polyneuropathy (CIDP):*** Improvement of neuromuscular disability and impairment and maintenance therapy to prevent relapse. ■ ***Adjunct in chronic lymphocytic leukemia:*** Prevention of bacterial infections in patients with hypogammaglobulinemia or recurrent bacterial infection associated with B-cell CLL. ■ ***Multifocal motor neuropathy (MMN):*** To improve muscle strength and disability in adult patients. ■ ***Kawasaki syndrome:*** Prevention of coronary artery aneurysms associated with Kawasaki syndrome. ■ Safety and effectiveness of ***Gammagard S/D, Gammaplex, Octagam 10%, and Panzyga*** for use in pediatric patients with chronic ITP have ***not*** been established; see Maternal/Child for additional limitations with other products. ■ Several formulations are approved for SC use in specific diagnoses; consult prescribing information.

Unlabeled uses:

There are numerous unlabeled uses; consult literature.

CONTRAINDICATIONS

Individuals known to have anaphylactic or severe hypersensitivity responses to the administration of human immune globulin. ■ IgA-deficient patients with pre-existing anti-IgA antibodies and a history of hypersensitivity. ■ ***Gammaplex*** is contraindicated in patients with hereditary intolerance to fructose; also contraindicated in infants and neonates for whom sucrose or fructose tolerance has ***not*** been established. ■ ***Octagam*** is contraindicated in patients with acute hypersensitivity to corn (contains maltose, which is derived from corn). ■ ***Privigen*** is contraindicated in patients with hyperprolinemia because it contains l-proline as a stabilizer.

PRECAUTIONS

Check label; must state, “For IV use.” ■ Some formulations may be given SC; however, all products must be given by IV infusion for ITP patients. Do not administer SC due to a potential risk for hematoma. ■ Hypersensitivity reactions have occurred; administer in a facility with adequate equipment and supplies to monitor the patient and respond to any medical emergency. ■ Use extreme caution in individuals with a history of prior systemic hypersensitivity reactions. Incidence of anaphylaxis may be increased, especially with repeated injections. IgA-deficient patients, especially those with antibodies against IgA, are at greater risk for developing severe hypersensitivity reactions. ■ Some packaging of these products may contain latex; use caution in sensitive individuals. ■ IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. Use extreme caution in patients with any degree of renal insufficiency; in patients age 65 years and older; in patients with diabetes mellitus, paraproteinemia, sepsis, or volume depletion; and/or in patients receiving known nephrotoxic drugs. If used, should be administered at the minimum dose and rate of infusion practicable. ***Products containing sucrose as a stabilizer (e.g., Carimune NF) have demonstrated an increased risk for renal dysfunction.*** Consider benefit versus risk before use. ■ Increases in SCr and/or BUN may progress to oliguria and anuria requiring dialysis; however, some patients improve spontaneously with discontinuation of IGIV. ■ May cause aseptic meningitis syndrome (AMS), especially with high doses (greater than 1 Gm/kg) and/or rapid infusion. May begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. Cerebrospinal fluid (CSF) studies are often positive with pleocytosis, predominantly from the granulocyte series and elevated protein levels. ■ Hyperproteinemia, with resultant changes in serum viscosity, and electrolyte imbalances (e.g., hyponatremia) may occur. Distinguish true hyponatremia from pseudohyponatremia to determine correct treatment. Decreasing serum-free water in patients with pseudohyponatremia may lead to volume depletion with a further increase in serum viscosity, which may predispose to thromboembolic events. ■ IGIV products have been associated with thrombotic events. Risk factors may include advanced age, prolonged immobilization, hypercoagulable conditions, history of venous or arterial thrombosis, use of estrogens, indwelling vascular catheter, hyperviscosity, and cardiovascular risk factors (e.g., cerebrovascular disease, coronary artery disease, diabetes, hypertension). Thrombosis may occur in the absence of known risk factors. If used, should be administered at the minimum dose and rate of infusion practicable. Ensure adequate hydration before administration. ■ Baseline assessment of blood viscosity should be made in patients at risk for hyperviscosity, including those with cryoglobins, fasting chylomicronemia, markedly high triglycerides, or monoclonal gammopathies. ■ May rarely cause hemolysis, which can result in hemolytic anemia due to enhanced RBC sequestration. High doses (greater than 2 Gm/kg) and non-O blood group may be risk factors for hemolysis. Cases of severe hemolysis-related renal dysfunction/failure or DIC have occurred following infusion; see Monitor. ■ Consider risk/benefit before use of high-dose regimens (greater than 1 Gm/kg) in chronic ITP patients at increased risk for acute kidney injury, hemolysis, thrombosis, or volume overload. ■ Hypertension, including hypertensive urgency, has been observed during and/or shortly after infusion. Patients with a history of hypertension may be at greater risk. Elevated BP may resolve within hours of infusion without therapy or may require adjustment in oral antihypertensive medicines. ■ Noncardiogenic pulmonary edema (transfusion-related acute lung injury [TRALI]) has been reported; see Monitor. ■ Derived from human blood. Despite purification processes, may carry risk of transmitting infectious agents (e.g., viruses [e.g., HIV, hepatitis] or Creutzfeldt-Jakob disease [CJD] agent). ■ Patients with gammaglobulinemia or extreme hypogammaglobulinemia who have never before received immunoglobulin substitution treatment or patients whose time from the last treatment is greater than 8 weeks may be at risk for developing inflammatory reactions (e.g., chills, fever, nausea, vomiting) on rapid infusion. Initiate slowly and increase rate as tolerated.

Monitor:

Use of larger veins recommended to reduce infusion-site discomfort, especially with 10% solutions. ■ Correct volume depletion before administration in all patients, especially patients with pre-existing renal insufficiency. ■ Recording of lot number on vials is recommended. ■ Monitor vital signs and observe patient continuously during infusion. A precipitous drop in BP or anaphylaxis can occur at any time. Emergency equipment and supplies must be at bedside. ■ Monitor renal function (e.g., BUN, SCr) and urine output in patients at increased risk for renal failure. Obtain baseline studies, monitor at intervals, and discontinue IGIV if renal function deteriorates. See Precautions. ■ Monitor for hyperproteinemia with resultant changes in serum viscosity and electrolyte imbalances. ■ Monitor for S/S of thrombosis and assess blood viscosity in patients at risk for hyperviscosity. ■ Monitor for S/S of hemolysis (e.g., lysis of red blood cells, liberation of hemoglobin), significant drop in hemoglobin or hematocrit, and hemolytic anemia. ■ Monitor for S/S of TRALI (e.g., fever, hypoxemia, normal left ventricular function, pulmonary edema, severe respiratory distress). Usually occurs within 1 to 6 hours after completion of the infusion. Manage with oxygen and adequate ventilatory support. If TRALI is suspected, both the product and the patient serum should be tested for the presence of antineutrophil antibodies. ■ Monitor for volume overload.

Patient Education:

Report chills, cyanosis, diaphoresis, dyspnea, faintness or light-headedness, fatigue, fever, headache, hives, itching or rash, neck pain or difficulty moving neck, tachycardia, wheezing. ■ Report chest pain or tightness, pain and/or swelling of an arm or a leg with warmth over the affected area, difficulty passing urine, decreased urine output, fluid retention, edema, shortness of breath, or sudden weight gain. ■ Remote risk of viral or CJD infection; consider risk versus benefit of therapy. See Drug/Lab Interactions.

Maternal/Child:

Category C: use with caution in pregnancy; no adverse effects documented, but adequate studies are not available. ■ Safety for use in breast-feeding not established. ■ Response in pediatric patients usually exceeds response in adults. ■ Safety and effectiveness of ***Gammagard S/D*** for use in pediatric patients with chronic ITP have not been established. ■ Safety and effectiveness of ***Gammagard S/D*** for use in Kawasaki disease have been established. ■ Use of ***Privigen*** to treat primary immunodeficiency in pediatric patients under 3 years of age or to treat chronic immune thrombocytopenic purpura in pediatric patients under 15 years of age not established. ■ Safety and effectiveness of ***Privigen*** have not been established in pediatric patients with CIPD who are under 18 years of age. ■ Safety and effectiveness of ***Bivigam*** for use in pediatric patients under 6 years of age not established. ■ Safety and effectiveness of ***Flebogamma 5% and 10%, Gammaplex, and Panzyga*** for use in pediatric patients under 2 years of age have not been established. ■ Safety and effectiveness of ***Octagam 10%*** for use in pediatric patients have not been established. ■ Safety and effectiveness of ***Gammagard Liquid*** for treatment of PI in pediatric patients under 2 years of age have not been established. ■ Safety and effectiveness of ***Panzyga*** for use in pediatric patients with chronic ITP have not been established. ■ Safety and effectiveness for use in pediatric patients with MMN have not been established. ■ Safety and effectiveness of ***Gammaked*** and ***Gamunex-C*** for use in pediatric patients with CIDP have not been established.

Elderly:

Use with extreme caution. Incidence of renal insufficiency, thrombosis, and other side effects increased due to age, potential for decreased organ function, and pre-existing medical conditions. Do not exceed recommended dose and infuse at the minimum infusion rate practicable; see Precautions.

DRUG/LAB INTERACTIONS

Do not administer **live virus vaccines** from 2 weeks before to at least 3 months after immune globulin IV. Passive transfer of antibodies may transiently interfere with the response to live virus vaccines, such as measles, mumps, rubella, and varicella; see prescribing information if there is a risk of measles exposure or if accidental exposure has occurred. ■ Provides immediate antibody levels that last for about 3 weeks. In selected patients, may have an immune-modulating effect that may alter their response to **corticosteroids or antineoplastic agents.** ■ Concurrent use with **nephrotoxic drugs** (e.g., aminoglycosides, amphotericin B, cidofovir, rifampin) may increase risk of renal insufficiency. ■ Products that contain **maltose (Octagam)** may interfere with blood and urine glucose tests. ■ Various antibody titers may be raised temporarily, resulting in **false-positive serologic testing.** ■ May cause a positive **direct or indirect antiglobulin (Coombs') test.**

SIDE EFFECTS

Arthralgia, asthenia, back pain, chills, diarrhea, dizziness, fatigue, fever, flushing, headache, hyperhidrosis, hypertension, infusion site pain/reactions, lethargy, nausea and vomiting, pharyngitis, rash, sinusitis, upper abdominal pain, and urticaria were reported most commonly. Full range of hypersensitivity symptoms, including anaphylaxis, is possible. Angioedema, erythema, fever, and urticaria are most frequently observed. Anxiety, chest tightness, cough, decreased diastolic BP, difficulty breathing, elevated ALT and AST (temporary), hemolytic anemia (reversible), increased BUN and SCr (may occur as soon as 1 to 2 days following infusion), leg cramps, light-headedness, malaise, migraine, myalgia, pharyngolaryngeal pain, and tachycardia have been reported. Severe reactions (e.g., circulatory collapse, fever, loss of consciousness, nausea and vomiting, sudden onset of dyspnea) have occurred and are more common in patients with antibody deficiencies. Noncardiogenic pulmonary edema (transfusion-related acute lung injury [TRALI]) has been reported. Acute renal failure, acute tubular necrosis, osmotic nephrosis, and proximal tubular nephropathy have been reported; may result in death. Is made from human plasma; process attempts to eliminate risk of hepatitis or HIV infection. A precipitous hypotensive reaction can occur and is most frequently associated with too-rapid rate of injection. Aseptic meningitis syndrome and hemolysis occur infrequently. See Precautions.

Post-Marketing:

Abdominal pain, apnea, ARDS, back pain, bronchospasm, bullous dermatitis, cardiac arrest, coma, cyanosis, dyspnea, epidermolysis, erythema multiforme, hepatic dysfunction, hypotension, hypoxemia, leukopenia, loss of consciousness, pancytopenia, positive direct antiglobulin (Coombs') test, pulmonary edema, seizures, Stevens-Johnson syndrome, thromboembolism, and tremor have been reported with IGIV products.

ANTIDOTE

Reduce rate for patient discomfort, for any sign of adverse reaction, and in patients at risk for renal insufficiency or thrombosis. If symptoms subside promptly, the infusion may be resumed at a lower rate. Decreasing the volume of subsequent infusions may also prevent or decrease the incidence of adverse reactions. Loop diuretics (e.g., furosemide [Lasix]) may be helpful in the management of fluid overload. Patients who continue to experience adverse reactions after rate and/or volume have been reduced may be premedicated with hydrocortisone 1 to 2 mg/kg 30 minutes before the immune globulin infusion. Pretreatment with acetaminophen and diphenhydramine or trying a different brand of immune globulin may also be useful. Discontinue the drug immediately for any signs of a hypersensitivity reaction, thrombotic event, or renal insufficiency. Notify the physician. May be treated symptomatically and infusion resumed at slower rate if symptoms subside. Treat anaphylaxis immediately. Epinephrine, diphenhydramine, oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Manage TRALI with oxygen and ventilatory support. Resuscitate as necessary.

INAMRINONE LACTATE

(in-**AM**-rih-nohn **LAK**-tayt)
Inotropic agent
pH 3.2 to 4

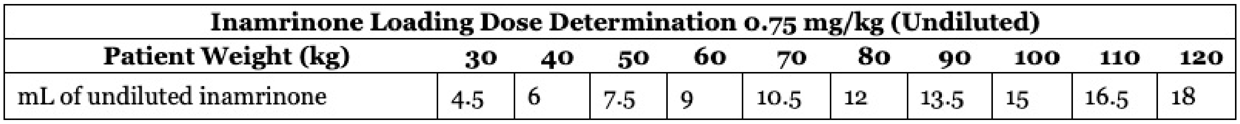
USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Inamrinone:

0.75 mg/kg of body weight as the initial loading dose (52.5 mg [10.5 mL] for a 70-kg person).



Inamrinone Loading Dose Determination 0.75 mg/kg (Undiluted)

Patient Weight (kg)	30	40	50	60	70	80	90	100	110	120
mL of undiluted inamrinone	4.5	6	7.5	9	10.5	12	13.5	15	16.5	18

Follow with a maintenance infusion of 5 to 10 mcg/kg/min. AHA guidelines recommend a maintenance infusion of 5 to 15 mcg/kg/min, titrated to clinical effect. The initial dose (0.75 mg/kg) may be repeated once in 30 minutes if indicated. Manufacturer recommends that the total dose, including the loading doses, not exceed 10 mg/kg/24 hr. Doses up to 18 mg/kg/24 hr have been used in a limited number of patients for shortened durations of therapy.

PEDIATRIC DOSE

0.75 mg/kg as the initial loading dose. May be repeated in 30 minutes if necessary. Another source suggests a dose of 3 to 4.5 mg/kg given in divided doses to the desired effect. AHA guidelines recommend 0.75 to 1 mg/kg as the initial loading dose and state that the loading dose may be repeated twice to a maximum dose of 3 mg/kg. See Usual Dose for weights over 30 kg. Maintain ***infants and pediatric patients*** with an infusion of 5 mcg (0.005 mg) to 10 mcg (0.01 mg)/kg/min and ***neonates*** with an infusion of 3 mcg (0.003 mg) to 5 mcg (0.005 mg)/kg/min. See Maternal/Child.

DOSE ADJUSTMENTS

May be required in impaired renal or hepatic function or if thrombocytopenia occurs. One source recommends a dose reduction of 25% to 50% in ***adults*** with a CrCl less than 10 mL/min. In ***pediatric patients*** the recommendation is a dose reduction of 50% with a CrCl from 10 to 29 mL/min and a dose reduction of 75% with a CrCl less than 10 mL/min.

DILUTION

Available in 100 mg/20 mL ampules or vials. May be given undiluted, or diluted with NS or ½NS to a final concentration of 1 to 3 mg/mL. Addition of 60 mL (300 mg) to 60 mL of solution will provide a final concentration of 2.5 mg/mL. May be given through Y-tube or three-way stopcock of IV infusion set. Use diluted solution within 24 hours.

Filters:

No data available from manufacturer.

Storage:

Store ampules or vials at CRT. Protect from light and freezing. Use diluted solution within 24 hours.

COMPATIBILITY

Manufacturer lists as **incompatible** with dextrose solutions (direct dilution only). States, "Forms an immediate precipitate with furosemide."

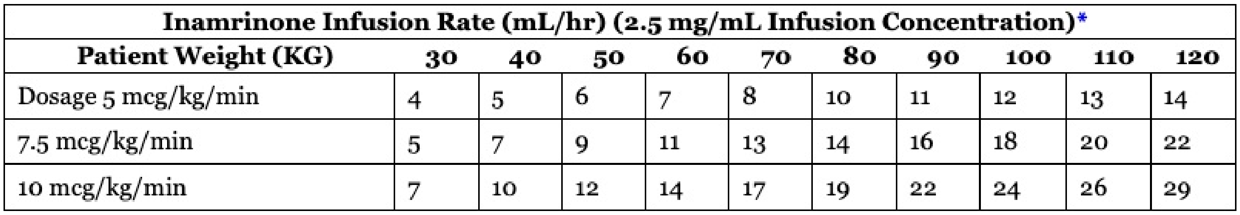
RATE OF ADMINISTRATION

Loading dose:

A single dose over 2 to 3 minutes. AHA guidelines recommend a single dose over 10 to 15 minutes in adults and over 5 minutes in pediatric patients.

Infusion:

Using a microdrip (60 gtt/mL) or an infusion pump, deliver inamrinone in recommended doses. See the following dosage chart defining selected dose in mcg/kg/min in mL/hr.



Inamrinone Infusion Rate (mL/hr) (2.5 mg/mL Infusion Concentration)*

Patient Weight (KG)	30	40	50	60	70	80	90	100	110	120
Dosage 5 mcg/kg/min	4	5	6	7	8	10	11	12	13	14
7.5 mcg/kg/min	5	7	9	11	13	14	16	18	20	22
10 mcg/kg/min	7	10	12	14	17	19	22	24	26	29

*A 70-kg patient receiving 7.5 mcg/kg/min would have a flow rate of 13 mL/hr with a 2.5 mg/mL concentration. Adjust as indicated by physician's orders and progress in patient's condition. Reduce rate or stop infusion for excessive drop in BP.

ACTIONS

A class of cardiac inotropic agent that differs in chemical structure and mode of action from digitalis glycosides and catecholamines. It has positive inotropic action with vasodilator activity. Reduces afterload and preload by direct relaxant effect on vascular smooth muscle. Cardiac output is increased without measurable increase in myocardial oxygen consumption or changes in arteriovenous oxygen difference. Pulmonary capillary wedge pressure, total peripheral resistance, diastolic BP, and mean arterial pressure are decreased. HR generally remains the same. With a bolus dose, peak effect occurs within 10 minutes. Continuous administration is required to maintain serum levels. Mean half-life is 3.6 hours. In patients with CHF, mean half-life is 5.8 hours (range 3 to 15). Metabolized by the liver. Excreted primarily in urine and to a small extent in feces.

INDICATIONS AND USES

Short-term management of congestive heart failure in patients who have not responded adequately to digoxin, diuretics, or vasodilators.

Unlabeled uses:

Short-term management of congestive heart failure, pulmonary hypertension, and postoperative low cardiac output in neonates and infants up to 2 years.

CONTRAINDICATIONS

Hypersensitivity to inamrinone or bisulfites, severe aortic or pulmonic valvular disease when surgical relief of the obstruction is required.

PRECAUTIONS

Experience in controlled trials does not extend beyond 48 hours. Long-term use of cyclic-AMP–dependent inotropes has been associated with increased risk of hospitalization and death. Patients with NYHA class IV symptoms appear to be at particular risk. ■ May increase ventricular response in atrial flutter/fibrillation. Pretreat with digoxin (recommended). ■ May be given to digitalized patients without causing signs of digoxin toxicity. ■ Use caution in impaired renal or liver function; serum levels may increase considerably. ■ Not recommended for use in the acute phase of myocardial infarction due to lack of clinical trials to date. ■ May aggravate outflow tract obstruction in hypertrophic subaortic stenosis. ■ Contains sulfites, use with caution in patients with allergies. ■ Tachyphylaxis has been reported, usually within 72 hours of starting therapy.

Monitor:

Obtain platelet count before and during therapy to monitor onset of thrombocytopenia. ■ Observe patient continuously; monitoring of ECG, cardiac index, pulmonary capillary wedge pressure, central venous pressure, and plasma concentration are recommended (steady state plasma concentrations of approximately 3 mcg/mL suggested). ■ Monitor BP, HR, urine output, and body weight. Observe for orthopnea, dyspnea, and fatigue. ■ Additional fluids and electrolytes may be required to facilitate appropriate response in patients who have been vigorously diuresed and may have insufficient cardiac filling pressure. Use caution. ■ Monitor electrolytes; hypokalemia secondary to improved cardiac output with improved diuresis may cause arrhythmias. ■ Monitoring of renal and liver function tests suggested. For marked increase in hepatic enzymes or S/S of hepatotoxicity, discontinue inamrinone. If increases in hepatic enzymes are less marked and no clinical symptoms of hepatotoxicity are present, continue inamrinone, decrease dose, or discontinue. Weigh risk versus benefit of continued therapy. ■ Monitor IV site; avoid extravasation.

Maternal/Child:

Category C: use during pregnancy only if benefits outweigh risks. ■ Safety during breast-feeding not established. ■ Safety for use in pediatric patients not established but has been used effectively. ■ Pediatric patients have a shorter elimination half-life.

Elderly:

No problems documented; consider possible renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May cause excessive hypotension with **disopyramide** (Norpace).

SIDE EFFECTS

Abdominal pain, anorexia, arrhythmias, burning at site of injection, chest pain, fever, hepatotoxicity, hypotension, nausea and vomiting, thrombocytopenia. Hypersensitivity reactions manifested by ascites, myositis with interstitial shadowing on chest x-ray and elevated sedimentation rate, pericarditis, pleuritis, vasculitis with nodular pulmonary densities, hypoxemia, and jaundice have been reported.

ANTIDOTE

Notify the physician of any side effect. Based on degree of severity and condition of the patient, may be treated symptomatically, and dose may remain the same, be decreased, or the inamrinone may be discontinued. Reduce rate or discontinue the drug at the first sign of marked hypotension and notify the physician. May be resolved by these measures alone or vasopressors (e.g., dopamine) may be required. Treat arrhythmias with the appropriate drug. Resuscitate as necessary.

INDOMETHACIN SODIUM

(in-doh-**METH**-ah-sin **SO**-dee-um)
Indocin IV
Prostaglandin inhibitor (patent ductus arteriosus adjunct)
pH 6 to 7.5

USUAL DOSE

Pretreatment:

Confirmation of diagnosis indicated; see Precautions.

Neonates:

Three IV doses, specific to age at first dose, given at 12- to 24-hour intervals constitute a course of therapy.

Less than 48 hours of age:

First dose (0.2 mg/kg of body weight), second dose (0.1 mg/kg), third dose (0.1 mg/kg).

2 to 7 days of age:

0.2 mg/kg for each of 3 doses.

Over 7 days of age:

First dose (0.2 mg/kg), then 0.25 mg/kg for the next 2 doses.

If ductus arteriosus reopens, a second course of 1 to 3 doses as described for each neonate age may be repeated one time given at 12- to 24-hour intervals. If neonate remains unresponsive to indomethacin therapy after 2 courses, surgery may be required for closure of the ductus arteriosus.

DOSE ADJUSTMENTS

If urine output is less than 0.6 mL/kg/hr at any time a dose is to be given, withhold dose until lab studies confirm normal renal function.

DILUTION

Each 1 mg must be diluted with at least 1 mL NS or SWFI without preservatives (0.1 mg/0.1 mL); may be diluted with 2 mL diluent (0.05 mg/0.1 mL). The preservative benzyl alcohol is toxic in neonates. A fresh solution should be prepared just before each administration. Discard any unused portion.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials in carton at CRT. Protect from light. Use reconstituted solution immediately.

COMPATIBILITY

Manufacturer states, “Prepare only with preservative-free NS or SWFI”; further dilution with IV solutions is not recommended and may precipitate with solutions with a pH below 6.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose, properly diluted, by IV injection over 20 to 30 minutes.

ACTIONS

A potent inhibitor of prostaglandin synthesis. Through an unconfirmed method of action (thought to be inhibition of prostaglandin synthesis), it causes closure of a patent ductus arteriosus 75% to 80% of the time, eliminating the need for surgical intervention.

Plasma half-life varies inversely with postnatal age and weight and ranges from 12 to 20 hours. Metabolized in the liver and eventually excreted in urine and bile.

INDICATIONS AND USES

Closure of a hemodynamically significant patent ductus arteriosus in premature infants weighing between 500 and 1,750 Gm if usual medical management (e.g., fluid restriction, diuretics, digoxin, respiratory support) has not been effective after 48 hours.

CONTRAINDICATIONS

Bleeding, especially active intracranial hemorrhage or GI bleeding; coagulation defects; necrotizing enterocolitis; infants with congenital heart disease (e.g., pulmonary atresia, severe coarctation of the aorta, severe tetralogy of Fallot) who require patency of the ductus arteriosus for satisfactory pulmonary or systemic blood flow; proven or suspected untreated infection; significant renal impairment; thrombocytopenia.

PRECAUTIONS

Clinical evidence of a hemodynamically significant patent ductus arteriosus (respiratory distress, a continuous murmur, a hyperactive precordium, cardiomegaly and pulmonary plethora on chest x-ray) should be present before use is considered. ■ For use only in a highly supervised setting such as an intensive care nursery. ■ May increase potential for GI or intraventricular bleeding. ■ Use caution in presence of existing controlled infection; may mask signs and symptoms of exacerbation. ■ May suppress water excretion to a greater extent than sodium excretion. Hyponatremia may result. ■ For IV use only. ■ Surgery indicated if condition is not responsive to two courses of therapy.

Monitor:

Vital signs, oxygenation, acid-base status, fluid and electrolyte balance, and kidney function (SCr, BUN, urine output) must be monitored and maintained. ■ Can cause marked reduction in urine output (over 50%), increase BUN and SCr, and reduce glomerular filtration rate and CrCl. These symptoms usually disappear when therapy is completed but may cause acute renal failure, especially in infants with impaired renal function from other causes. ■ May inhibit platelet aggregation; monitor for signs of bleeding. ■ Discontinue drug if signs of impaired liver function appear. ■ Confirm absolute patency of vein. Avoid extravasation; will irritate tissue. ■ See Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

May reduce elimination and increase serum concentrations of **drugs that are renally excreted** (e.g., aminoglycosides, digoxin). Monitor drug levels and adjust doses as needed to avoid toxicity. ■ Observe neonate closely for signs of **digoxin toxicity;** frequent monitoring of ECG and digoxin serum levels is indicated. ■ Use with **furosemide** may help to maintain renal function. ■ Concomitant use with **anticoagulants** may increase risk of bleeding; monitoring of PT suggested. ■ Coadministration with **ACE inhibitors** (e.g., enalapril) may result in deterioration of renal function, including renal failure.

SIDE EFFECTS

Abdominal distension; acidosis; alkalosis; apnea; bleeding into the GI tract (gross or microscopic); bradycardia; DIC; elevated BUN or creatinine; exacerbation of preexisting pulmonary infection; fluid retention; gastric perforation; hyperkalemia; hypoglycemia; hyponatremia; intracranial bleeding; necrotizing enterocolitis; oliguria; oozing from needle puncture sites; pulmonary hemorrhage; pulmonary hypertension; reduced urine sodium, chloride, potassium, urine osmolality, free water clearance, or glomerular filtration rate; renal failure; retrolental fibroplasia; thrombocytopenia; transient ileus; uremia; vomiting.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Based on severity, side effects may be treated symptomatically or drug will be completely discontinued in favor of surgical intervention. Resuscitate as necessary.

INFLIXIMAB BBW ■ INFLIXIMAB-dyyb[a] ■ INFLIXIMAB-abda[a] BBW ■ INFLIXIMAB-axxq[a] BBW ■ INFLIXIMAB-qbtx[a] BBW

(in-**FLIX**-ih-mab)

Remicade, Inflectra[a], Renflexis[a], Ixifi[a], Avsola[a]
Monoclonal antibody
Inflammatory bowel disease agent
Antirheumatic agent
TNF-blocking agent
pH 7.2 (Avsola, Inflectra, and Remicade) ■ pH 6.2 (Renflexis) ■ pH 6 (Ixifi)

USUAL DOSE

Infliximab-dyyb (Inflectra)[a], infliximab-abda (Renflexis)[a], infliximab-qbtx (Ixifi)[a], and infliximab-axxq (Avsola)[a] are biosimilar drugs to infliximab (Remicade). Unless specifically stated otherwise, the use of the name infliximab or infliximab product(s) applies to all formulations.

Pretreatment:

Patients should be tested for latent tuberculosis before infliximab use and periodically during therapy. Treatment for latent infection should be initiated before infliximab therapy. Patients should be tested for hepatitis B virus before infliximab use. See Precautions and Monitor.

Premedication:

Administer at the physician's discretion. May include antihistamines (e.g., diphenhydramine), H_2 blockers (e.g., famotidine), acetaminophen, and/or corticosteroids (e.g., hydrocortisone).

Crohn's disease and fistulizing Crohn's disease:

Begin with an initial dose of 5 mg/kg as an IV infusion. Repeat at 2 and 6 weeks and every 8 weeks thereafter. For patients who respond and then lose their response, consideration may be given to treatment with 10 mg/kg. If there is no response by Week 14, response with continued dosing is unlikely; consider discontinuing infliximab. See Precautions.

Rheumatoid arthritis:

3 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter. Given in combination with methotrexate. See methotrexate monograph. If response to infliximab is incomplete, dose may be adjusted up to 10 mg/kg or interval decreased to every 4 weeks. Risk of infection may be increased at higher doses.

Ankylosing spondylitis:

5 mg/kg as an IV infusion. Repeat at 2 and 6 weeks, then every 6 weeks thereafter.

Psoriatic arthritis:

5 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter. May be used with or without methotrexate.

Ulcerative colitis:

5 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter.

Plaque psoriasis:

5 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks, then every 8 weeks thereafter.

PEDIATRIC DOSE

Pretreatment:

See comments in Usual Dose and Maternal/Child.

Crohn's disease:

5 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks. Follow with a maintenance regimen of 5 mg/kg every 8 weeks.

Ulcerative colitis:

5 mg/kg as an IV infusion. Repeat dose at 2 and 6 weeks. Follow with a maintenance regimen of 5 mg/kg every 8 weeks.

DOSE ADJUSTMENTS

Do not exceed a dose of 5 mg/kg in patients with moderate to severe CHF (NYHA Class

III/IV); see Contraindications.

DILUTION

Each vial contains 100 mg of infliximab. When reconstituted as directed below, each milliliter of solution contains 10 mg of infliximab. Calculate the dose and the number of vials required and the total volume of reconstituted infliximab solution required. Reconstitute each 100-mg vial with 10 mL of SWFI, using a syringe equipped with a 21-gauge or smaller needle. Direct the stream of SWFI to side of vial. Swirl gently; do not shake. Allow reconstituted solution to stand for 5 minutes. Solutions of ***Remicade, Avsola, Inflectra,*** and ***Renflexis*** should be colorless to light yellow and opalescent. ***Ixifi*** should be colorless to light brown and opalescent. All products may develop a few translucent particles as infliximab is a protein. Do not use if opaque particles, discoloration, or other foreign particles are present. The total dose of reconstituted solution must be further diluted with NS to a final volume of 250 mL. (May withdraw a volume of NS equal to the calculated volume of reconstituted infliximab from a 250-mL bottle or bag of NS and slowly add reconstituted solution.) Do not dilute the reconstituted infliximab solution with any other diluent. Mix gently. Infusion concentration should range between 0.4 mg/mL and 4 mg/mL.

Filters:

Must be administered through an infusion set with an in-line, sterile, nonpyrogenic, low–protein binding filter (pore size equal to or less than 1.2 microns). Flush and prime tubing/filter system with NS before administration of infusion.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Protect Avsola from light. Discard any unused portion. Do not use beyond expiration date on vial. The infusion should begin within 3 hours of reconstitution and dilution. ***Remicade, Avsola, and Ixifi:*** Unopened vials may also be stored at temperatures up to a maximum of 30° C (86° F) for a single period of up to 6 months but not exceeding the original expiration date. The new expiration date must be written on the carton. Upon removal from refrigerated storage, **Remicade, Avsola, and Ixifi** cannot be returned to refrigerated storage.

COMPATIBILITY

Manufacturer recommends not infusing concomitantly in the same IV line with other agents until specific **compatibility** data are available.

RATE OF ADMINISTRATION

Begin the infusion within 3 hours of reconstitution and dilution. Flush and prime tubing/filter system with NS before administration. A single dose should be given over a period of not less than 2 hours. Upon completion of infusion, IV line should be flushed thoroughly NS to ensure all active drug is delivered to the patient. Patients experiencing a mild to moderate infusion-related reaction may be able to continue therapy at a reduced rate; see Antidote.

ACTIONS

A chimeric IgG1k monoclonal antibody that binds specifically to human tumor necrosis factor alpha (TNFα). Is composed of human constant and murine variable regions. Produced by a recombinant cell line cultured by continuous perfusion and purified by a series of steps that include measures to inactivate and remove viruses. Neutralizes the biologic activity of TNFα by binding with high affinity to the soluble and transmembrane forms of TNFα and inhibiting binding of TNFα with its receptors. Infliximab does not neutralize TNFβ. Biologic activities attributed to TNFα include induction of pro-inflammatory cytokines such as IL-1 and IL-6, enhancement of leukocyte migration by increasing endothelial layer permeability and expression of adhesion molecules by endothelial cells and leukocytes, activation of neutrophil and eosinophil functional activity, and induction of acute phase reactants and other liver proteins, as well as tissue-degrading enzymes produced by synoviocytes and/or chondrocytes. Elevated concentrations of TNFα have been found in involved tissues and fluids of patients with Crohn’s disease, rheumatoid arthritis, ankylosing spondylitis, ulcerative colitis, psoriatic arthritis, and plaque psoriasis. These elevated concentrations correlate with elevated disease activity. Treatment with infliximab blocks the biological activities attributed to TNFα. Infliximab is distributed predominantly within the vascular space. Has a prolonged terminal half-life of 7.7 to 9.5 days.

INDICATIONS AND USES

Adult and pediatric patients 6 years of age and older:

Reduce the S/S and induce and maintain clinical remission in patients with moderately to severely active Crohn’s disease who have had an inadequate response to conventional therapy. ■ Reduce the S/S and induce and maintain clinical remission and mucosal healing, and eliminate corticosteroid use in patients with moderately to severely active ulcerative colitis who have had an inadequate response to conventional therapy; see Maternal/Child.

Adult patients:

Reduce the number of draining enterocutaneous and rectovaginal fistula(s) and maintain fistula closure in fistulizing Crohn’s disease. ■ Given in combination with methotrexate to improve physical function, inhibit progression of structural damage, and reduce S/S in patients with moderately to severely active rheumatoid arthritis. ■ Reduce S/S in active ankylosing spondylitis. ■ Reduce the S/S of active arthritis, inhibit progression of structural damage, and improve physical function in patients with psoriatic arthritis. ■ Used for treatment of patients with chronic severe (i.e., extensive and/or disabling) plaque psoriasis who are candidates for systemic treatment and when other systemic treatments are less appropriate.

CONTRAINDICATIONS

Known hypersensitivity to infliximab, murine proteins, or other components of the product. ■ Administration of doses exceeding 5 mg/kg in patients with moderate to severe (NYHA Class III/IV) CHF.

PRECAUTIONS

Administer in a facility that is equipped to monitor the patient and respond to any medical emergency. ■ TNFα mediates inflammation and modulates cellular immune response. Anti-TNF therapies, including infliximab, may affect normal immune responses. ■ Patients treated with infliximab are at increased risk for developing serious infections that may lead to hospitalization or death. Many of the serious infections have occurred in patients undergoing concomitant immunosuppressive therapy (e.g., methotrexate, corticosteroids) that, in addition to their underlying disease, may predispose them to infections; see Drug/Lab Interactions. Discontinue infliximab if patient experiences a serious infection or sepsis. Reported infections with TNF-blockers include active tuberculosis, including reactivation of latent tuberculosis; invasive fungal infections (e.g., histoplasmosis, coccidioidomycosis, cryptococcus, candidiasis, aspergillosis, blastomycosis, and pneumocystosis); and bacterial, viral, parasitic, and other infections due to opportunistic pathogens, including Legionella, Listeria, and *Salmonella*. ■ Patients with TB have frequently presented with disseminated or extrapulmonary disease. ■ Cases of tuberculosis reactivation or new tuberculosis infections have been observed in patients receiving infliximab, including patients who have previously received treatment for latent or active tuberculosis. Cases of active tuberculosis have also occurred in patients being treated with infliximab during treatment for latent tuberculosis. ■ Antituberculosis treatment of patients with a reactive TB skin test reduces the risk of TB reactivation in patients receiving infliximab. ■ Patients with histoplasmosis or other invasive fungal infections may present with disseminated rather than localized disease. Antigen and antibody testing for histoplasmosis may be negative. ■ Treatment with infliximab should not be initiated in patients with an active infection, including clinically important localized infections. Consider the risks and benefits of infliximab treatment before initiating therapy in patients with chronic or recurrent infection, patients who have been exposed to TB, patients with a history of an opportunistic infection, patients who have resided in or traveled to areas of endemic tuberculosis or endemic mycoses (e.g., histoplasmosis, coccidioidomycosis, or blastomycosis), or patients with underlying conditions that may predispose them to infection. ■ Has been associated with the reactivation of hepatitis B virus (HBV) in patients who are chronic hepatitis B carriers (i.e., surface antigen–positive). Fatalities have been reported. ■ Infliximab therapy has been associated with adverse outcomes in patients with heart failure and should be used in these patients only after consideration of other treatment options. Studies suggest a higher mortality in patients who receive 10 mg/kg, and higher rates of cardiovascular adverse events at doses of 5 mg/kg and 10 mg/kg. Do not use doses greater than 5 mg/kg in patients with moderate to severe CHF; see Contraindications. Discontinue for new-onset CHF or for worsening CHF. Use with caution in patients with mild CHF (NYHA Class I/II); monitor closely. ■ Hypersensitivity reactions characterized by urticaria, dyspnea, and/or hypotension have occurred in association with infliximab infusion. Most occur during or within 2 hours of the infusion. Discontinue infusion if severe reactions occur. Medications for management of hypersensitivity reaction (e.g., acetaminophen, diphenhydramine, corticosteroids [e.g., hydrocortisone] and/or epinephrine) should be readily available. ■ Serum sickness–like reactions (dysphagia, fever, hand and facial edema, headache, myalgias, polyarthralgias, rash, sore throat) have been reported and have occurred as early as after the second dose and when infliximab was interrupted and then re-initiated after an extended period. These reactions are associated with a marked increase in antibodies to infliximab, a loss of detectable serum concentrations of infliximab, and a possible loss of drug efficacy. ■ Readministration of infliximab after a period of no treatment resulted in a higher incidence of infusion reactions relative to regular maintenance treatment in clinical trials. Evaluate risk versus benefit of readministration after a period of no treatment, especially if considering a re-induction regimen given at 0, 2, and 6 weeks. For cases in which maintenance therapy for psoriasis has been interrupted, infliximab should be re-initiated with a single dose followed by maintenance therapy. ■ Serious cerebrovascular accidents, myocardial ischemia/infarction (some fatal), hypotension, hypertension, and arrhythmias have been reported during and within 24 hours of initiation of infliximab infusion. Transient vision loss has been reported during or within 2 hours of initiation of infliximab infusion. ■ Infliximab therapy may result in formation of autoimmune antibodies and, rarely, in the development of a lupus-like syndrome. Discontinue therapy if this occurs. In clinical studies, symptoms resolved with discontinuation of therapy. ■ Lymphoma and other malignancies, some fatal, have been reported in children, adolescent, and young adult patients treated with TNF blockers, including infliximab. Most of the affected patients were receiving concomitant immunosuppressants. ■ Cases of hepatosplenic T-cell lymphoma have been reported. The majority of reported cases have occurred in adolescents and young adult males being treated with infliximab for Crohn’s disease or ulcerative colitis. This type of lymphoma has a very aggressive disease course and is usually fatal. Almost all affected patients received concomitant treatment with a TNF-blocker and azathioprine or 6-mercaptopurine (Purinethol) at or before diagnosis. When treating patients with inflammatory bowel disease, particularly adolescents and young adults, the decision whether to use infliximab alone or in combination with other immunosuppressants should consider the possibility that there is a higher risk of developing hepatosplenic T-cell lymphoma (HSTCL) with combination therapy versus an observed increased risk of immunogenicity and hypersensitivity reactions with infliximab monotherapy. ■ Use caution in patients with moderate to severe COPD; may have an increased risk of malignancy, especially of the lungs and head or neck. ■ The potential role of TNF-blocking therapy in the development of lymphoma, leukemia, melanoma, Merkel cell carcinoma, and other malignancies is not known. Patients with Crohn’s disease, ulcerative colitis, rheumatoid arthritis, or plaque psoriasis, particularly with highly active disease and/or exposure to immunosuppressant therapies, may be at higher risk (up to several-fold) than the general population for the development of lymphoma, leukemia, and other malignancies, even in the absence of TNF-blocking therapy. Use caution when considering infliximab therapy in patients with a history of malignancy or when continuing treatment in patients who develop a malignancy while receiving infliximab. ■ In clinical trials, nonmelanoma skin cancers were more common in psoriasis patients with previous phototherapy. ■ Women treated with infliximab for rheumatoid arthritis may have an increased risk of invasive cervical cancer. ■ Rare cases with CNS manifestations of systemic vasculitis, seizures, and new-onset or exacerbation of clinical symptoms and/or radiographic evidence of CNS demyelinating disorders (e.g., multiple sclerosis, optic neuritis) and peripheral demyelinating disorders (e.g., Guillain-Barré syndrome) have been reported. Use with caution in patients with any of these existing neurologic disorders. Consider discontinuing therapy if any of these disorders develop. ■ Severe hepatic reactions, including liver failure, jaundice, hepatitis, cholestasis, and autoimmune hepatitis, have been reported. Reactions have occurred anywhere from 2 weeks to more than a year after initiation of treatment and have resulted in death or the need for a liver transplant. ■ Leukopenia, neutropenia, thrombocytopenia, and pancytopenia, some with fatal outcome, have been reported. ■ Use caution when switching between biological disease-modifying antirheumatic drugs (e.g., **abatacept**, **anakinra**), **or other TNF-blocking agents** (e.g., adalimumab, etanercept, golimumab); overlapping biological activity may further increase the risk of infection; see Drug/Lab Interactions. ■ Administration of live virus vaccines or therapeutic infectious agents (e.g., BCG bladder instillation for treatment of cancer) concurrently with infliximab is not recommended. Could result in clinical infections, including disseminated infections. ■ See Drug/Lab Interactions and Maternal/Child.

Monitor:

Evaluate patients for tuberculosis risk factors and test for latent infection before initiating infliximab and periodically during therapy. Initiate treatment of latent TB before therapy with infliximab. Antituberculosis therapy should also be considered before initiating infliximab in patients with a history of latent or active tuberculosis for whom an adequate course of treatment cannot be confirmed and in patients with a negative test for latent tuberculosis but risk factors for tuberculosis infection. Consultation with a physician with expertise in the treatment of TB is recommended to aid in deciding whether initiating antituberculosis therapy is appropriate for a given patient. ■ During and after treatment, monitor for the development of tuberculosis in patients who tested negative for latent tuberculosis infection before initiating therapy. Tests for latent tuberculosis infection may also be falsely negative while on therapy with infliximab. Tuberculosis should be strongly considered in patients who develop a new infection during infliximab therapy, especially in patients who have previously or recently traveled to countries with a high prevalence of TB or who have had close contact with a person with active TB. ■ Before initiating TNF-blocker therapy, including infliximab, patients should be tested for HBV infection. Consultation with a physician with expertise in the treatment of hepatitis B is recommended if a patient tests positive for hepatitis B surface antigen. ■ In patients who are carriers of HBV and require treatment with TNF-blockers, closely monitor for clinical and laboratory signs of active HBV infection throughout treatment and for several months after completion of treatment. If HBV reactivation occurs, discontinue infliximab; see Antidote. ■ Monitor for S/S of infection during and after treatment; discontinue if a serious infection occurs and initiate appropriate antimicrobial treatment. Empiric antifungal therapy may be appropriate pending results of a diagnostic workup in patients at risk for invasive fungal infections (e.g., patients who reside or travel in regions where mycoses are endemic); see Precautions. ■ Monitor cardiac status closely for new-onset or worsening CHF; see Precautions. ■ Patients may develop antibodies to infliximab. In clinical trials, patients who were antibody-positive were more likely to have higher rates of clearance and reduced efficacy and to experience an infusion reaction than were patients who were antibody-negative. The incidence of antibody development was lower among patients receiving immunosuppressant therapies (e.g., 6-mercaptopurine, azathioprine, corticosteroids). ■ Monitor for S/S of hepatotoxicity (e.g., jaundice and/or marked liver enzyme elevations [equal to or greater than 5 times the upper limit of normal]). ■ Monitor CBC with differential and platelet count periodically. ■ Monitor for S/S of hypersensitivity or infusion reaction (e.g., anaphylaxis, chills, dyspnea, fever, flu-like symptoms, GI symptoms, headache, hypotension, rash). ■ Monitor for S/S of malignancies such as HSTCL (e.g., abdominal pain, hepatomegaly, night sweats, persistent fever, weight loss) and lymphoma. ■ Periodic skin examination is recommended for all patients, particularly those with risk factors for skin cancer. ■ Screen women for cervical cancer periodically.

Patient Education:

Read manufacturer's medication guide before each treatment with infliximab. ■ Tell health care professionals of heart conditions, previous or current infections, and recent or past exposure to TB or mycoses (e.g., histoplasmosis, coccidioidomycosis, blastomycosis). ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Promptly report abdominal pain, fever, S/S of new or worsening heart failure (e.g., shortness of breath, swelling feet, sudden weight gain), infection, numbness, tingling, or visual disturbances. ■ Report S/S of hypersensitivity reactions (e.g., itching, rash, swelling in the throat). Usually occur during or immediately following the infusion but may occur from 3 to 12 days later. ■ Report changes of growths on your skin during or after infliximab treatment. ■ Report symptoms of a cytopenia such as bruising, bleeding, or persistent fever. ■ Report recently receiving or being scheduled to receive a live virus vaccine or treatment with a weakened bacteria (such as BCG for bladder cancer) to your physician.

Maternal/Child:

Remicade:

Category B: use during pregnancy only if clearly needed. ■ Has potential for harm to the nursing infant; discontinue breast-feeding.

Avsola, Inflectra, Ixifi, and Renflexis:

Available data from published literature on the use of infliximab products during pregnancy have not reported a clear association of infliximab products with adverse pregnancy outcomes. ■ Available information is insufficient to inform the amount of infliximab products present in human milk and the effects on the breast-fed infant. There are no data on the effects of infliximab products on milk production. Consider risk versus benefit.

All products:

At least a 6-month waiting period following birth is recommended before the administration of any live vaccine to infants exposed in utero to infliximab. Infliximab crosses the placental barrier and has been detected in these infants up to 6 months after the last dose of infliximab to the mother, and these infants may be at increased risk for infection. ■ Safety and effectiveness for use in pediatric patients with ulcerative colitis and/or Crohn’s disease who are under 6 years of age not established. ■ Effectiveness of infliximab in inducing and maintaining mucosal healing could not be established in pediatric patients. ■ Safety and effectiveness for use in pediatric patients with juvenile rheumatoid arthritis was evaluated in a multicenter trial. The study failed to establish effectiveness; see prescribing information for details. ■ Before initiating infliximab therapy in pediatric patients with Crohn’s disease or ulcerative colitis, all vaccinations should be brought up-to-date. ■ Long-term (greater than 1 year) safety and effectiveness in pediatric patients with Crohn’s disease not established.

Elderly:

Specific differences in safety and effectiveness not noted; the incidence of serious side effects may be increased. An increase in the incidence of serious infections has been noted in patients 65 years and older, and because there is a higher incidence of infections in the elderly population in general, caution should be used in treating the elderly. See Precautions.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ Concurrent administration with **anakinra**, an antirheumatic interleukin-1 antagonist, **or abatacept**, an antirheumatic selective T-cell costimulation blocker, may be associated with an increased risk of serious infections. The added benefit of combination therapy has not been documented. Anakinra is also associated with an increased risk of neutropenia. Concurrent administration of TNF α-blocking agents (e.g., infliximab) with anakinra or abatacept is not recommended. ■ May cause increased immunosuppression and increased risk of infection with **tocilizumab**; concurrent use should be avoided. ■ Concurrent use of infliximab with **other biological products** (adalimumab, etanercept, golimumab, rituximab) used to treat the same conditions as infliximab is not recommended; may increase risk of infection. ■ The majority of patients with Crohn’s disease, rheumatoid arthritis, or psoriatic arthritis received one or more of the following concomitant medications without evidence of any type of negative drug interaction: aminosalicylates, antibiotics, antivirals, corticosteroids, 6-mercaptopurine (Purinethol), azathioprine, folic acid, methotrexate, narcotics, NSAIDs, and sulfasalazine. ■ Patients receiving **immunosuppressants** (e.g., 6-mercaptopurine, azathioprine, corticosteroids) tended to experience fewer infusion reactions as compared to patients on no immunosuppressants. ■ Concomitant **methotrexate** use may decrease incidence of anti-infliximab antibody production and increase infliximab concentrations. ■ **Live virus vaccines and therapeutic infectious agents** (e.g., BCG for bladder instillation for treatment of cancer) should not be given concurrently with infliximab. Could result in clinical infection, including disseminated infection. In addition, it is also recommended that live vaccines not be given to infants after in utero exposure to infliximab for at least 6 months following birth; see Precautions and Maternal/Child. ■ Cytochrome P_{450} enzymes may be suppressed by increased levels of cytokines during inflammation. Infliximab antagonizes cytokine activity, and the formation of the CYP450 enzymes may be normalized. When initiating or discontinuing infliximab in patients treated with **CYP450 substrates with a narrow therapeutic index,** monitoring of the effect (e.g., warfarin) or drug concentrations (e.g., cyclosporine or theophylline) is recommended. Dose adjustment may be necessary.

SIDE EFFECTS

Adult:

The most commonly reported side effects include abdominal pain, headache, infection (e.g., pharyngitis, sinusitis, upper respiratory tract, and urinary tract), and infusion-related reactions. The most common reasons for discontinuation of therapy were infusion-related reactions (e.g., dyspnea, fever, flushing, headache, rash) occurring during or within 2 hours of infusion or infections (bacterial, fungal, parasitic, and viral), including TB and invasive opportunistic infections (e.g., histoplasmosis, listeriosis, and pneumocystosis). See Precautions. Other less common side effects include arthralgia, autoantibodies/lupus-like syndrome, bronchitis, cough, diarrhea, dyspepsia, hepatitis B virus reactivation, hepatotoxicity (autoimmune hepatitis, increased liver function tests, jaundice, liver failure), hypertension, malignancies including lymphoma, moniliasis, nausea, new-onset or worsening CHF, pain, pruritus, and rash. Hematologic reactions, neurologic reactions, and deaths have been reported. See Precautions.

Pediatric patients with Crohn’s disease:

Anemia, bacterial infection, bone fracture, flushing, leukopenia, neutropenia, respiratory tract allergic reactions, and viral infections were reported more commonly in pediatric patients than in adult patients receiving similar treatment regimens. Serious side effects were infections (some fatal), including opportunistic infections and tuberculosis, infusion reactions, and hypersensitivity reactions.

Pediatric patients with ulcerative colitis:

Adverse reactions were similar to those seen in adult patients.

Post-Marketing:

Agranulocytosis (including infants exposed in utero to infliximab), cholestasis, erythema multiforme, hepatitis, idiopathic and/or thrombotic thrombocytopenic purpura, infusion-related reactions (cases of anaphylactic reactions, including anaphylactic shock, laryngeal/pharyngeal edema and severe bronchospasm; seizures; transient vision loss; cerebrovascular accidents; myocardial ischemia/infarction; and arrhythmia), interstitial lung disease (including pulmonary fibrosis/interstitial pneumonitis and rapidly progressive disease), jaundice, liver failure, malignancies (including leukemia, melanoma, Merkel cell carcinoma, and cervical cancer), myocardial ischemia/infarction, neuropathies, neutropenia, pericardial effusion, peripheral demyelinating disorders (e.g., Guillain-Barré syndrome, chronic inflammatory demyelinating polyneuropathy, and multifocal motor neuropathy), psoriasis (including new-onset and pustular, primarily palmar/plantar), Stevens-Johnson syndrome, systemic and cutaneous vasculitis, toxic epidermal necrolysis, transverse myelitis, and vaccine breakthrough infections (including bovine tuberculosis [disseminated BCG infection] following vaccination in an infant exposed in utero to infliximab) have been reported; fatalities have occurred.

Pediatric patients:

Hypersensitivity reactions, infections (including opportunistic infections and tuberculosis), infusion reactions, malignancies (including hepatosplenic T-cell lymphomas), lupus-like syndromes and the development of autoantibodies, and transient hepatic enzyme abnormalities.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue infliximab if patient experiences a serious infection, significant changes in vital signs, new or worsening S/S of heart failure, hepatotoxicity, a serious hypersensitivity reaction, a lupus-like syndrome (fever, pleuritic pain, pleural effusion), a neurologic disorder, or significant hematologic abnormalities. Treat hypersensitivity and/or infusion reactions with acetaminophen, antihistamines (diphenhydramine), corticosteroids, dopamine, and epinephrine as indicated. Slow or suspend infusion for a mild or moderate infusion-related reaction. Upon resolution of the reaction, re-initiation at a lower infusion rate and/or therapeutic administration of antihistamines, acetaminophen, and/or corticosteroids may be attempted with caution. If patient does not tolerate the infusion after these interventions, infliximab should be discontinued; see Usual Dose. Lupus-like syndrome usually subsides within 10 days of discontinuing infliximab. Discontinue infliximab in patients who develop HBV reactivation, and initiate antiviral therapy with appropriate supportive treatment. Safety of resuming therapy after HBV is controlled is not known; use caution if resumption of therapy is considered, and monitor closely.

INOTUZUMAB OZOGAMICIN BBW

(in-oh-**TOOZ**-ue-mab **OH**-zoe-ga-**MYE**-sin)
Besponsa
Antineoplastic
Monoclonal antibody
CD22-directed antibody-drug conjugate
pH 8

USUAL DOSE

Pretreatment for patients with circulating lymphoblasts:

Cytoreduction with a combination of hydroxyurea, steroids, and/or vincristine to a peripheral blast count of 10,000/mm^3 or less is recommended before the first dose.

Pretreatment for all patients:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication for all patients:

Premedication with a corticosteroid, an antipyretic, and an antihistamine is recommended before each dose.

Dosing Regimen for Cycle 1 and Subsequent Cycles Depending on Response to Treatment			
	Day 1	**Day 8**[a]	**Day 15**[a]
Dosing Regimen for Cycle 1			
All patients			
Dose[b]	0.8 mg/M^2	0.5 mg/M^2	0.5 mg/M^2
Cycle length	21 days[c]		
Dosing Regimen for Subsequent Cycles Depending on Response to Treatment			
Patients who have achieved a CR[d] **or CRi**[e]			
Dose[b]	0.5 mg/M^2	0.5 mg/M^2	0.5 mg/M^2
Cycle length	28 days[f]		
Patients who have not achieved a CR[d] **or CRi**[e]			
Dose[b]	0.8 mg/M^2	0.5 mg/M^2	0.5 mg/M^2
Cycle length	28 days[f]		

CR, Complete remission; *CRi,* complete remission with incomplete hematologic recovery**.**

[a] ±2 days (maintain minimum of 6 days between doses).

[b] Dose is based on patient's body surface area (M^2).

[c] For patients who achieve a CR or CRi, and/or to allow for recovery from toxicity, cycle length may be extended up to 28 days (i.e., 7-day treatment-free interval starting on Day 21).

[d] CR is defined as fewer than 5% blasts in the bone marrow and the absence of peripheral blood leukemic blasts, full recovery of peripheral blood counts (platelets 100,000/mm^3 or greater and absolute neutrophil counts [ANC] 1,000/mm^3 or greater), and resolution of any extramedullary disease.

[e] CRi is defined as fewer than 5% blasts in the bone marrow and the absence of peripheral blood leukemic blasts, incomplete recovery of peripheral blood counts (platelets less than 100,000/mm^3 and/or ANC less than 1,000/mm^3), and resolution of any extramedullary disease.

[f] 7-day treatment-free interval starting on Day 21.

Patients who do not achieve a CR or CRi within 3 cycles should discontinue treatment.

Patients proceeding to hematopoietic stem cell transplant (HSCT):

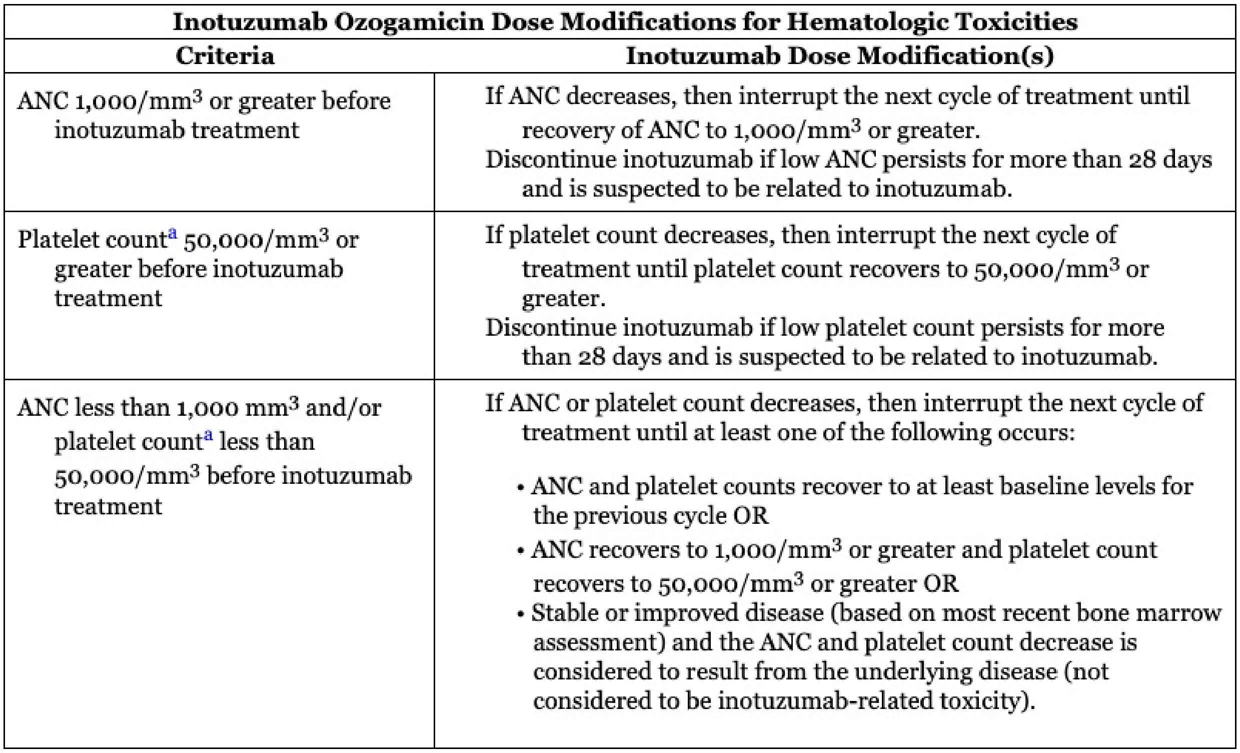
Recommended duration of treatment with inotuzumab is 2 cycles. A third cycle may be considered for patients who do not achieve CR or CRi and minimal residual disease (MRD) negativity after 2 cycles.

Patients not proceeding to HSCT:

Additional cycles of treatment (up to a maximum of 6 cycles) may be administered.

DOSE ADJUSTMENTS

No dose adjustments required based on age, race, sex, renal impairment, or in patients with a total bilirubin 1.5 times the ULN or less and AST/ALT 2.5 times the ULN or less. There is limited safety information for patients with moderate or severe hepatic impairment before dosing is initiated. ■ Modify dose based on toxicities as outlined in the following charts. Doses within a treatment cycle (i.e., Days 8 and/or 15) do not need to be interrupted due to neutropenia or thrombocytopenia, but dosing interruptions within a cycle are recommended for nonhematologic toxicities. If the dose is reduced due to inotuzumab-related toxicity, the dose must not be re-escalated.



Inotuzumab Ozogamicin Dose Modifications for Hematologic Toxicities

Criteria	Inotuzumab Dose Modification(s)
ANC 1,000/mm^3 or greater before inotuzumab treatment	If ANC decreases, then interrupt the next cycle of treatment until recovery of ANC to 1,000/mm^3 or greater. Discontinue inotuzumab if low ANC persists for more than 28 days and is suspected to be related to inotuzumab.
Platelet count[a] 50,000/mm^3 or greater before inotuzumab treatment	If platelet count decreases, then interrupt the next cycle of treatment until platelet count recovers to 50,000/mm^3 or greater. Discontinue inotuzumab if low platelet count persists for more than 28 days and is suspected to be related to inotuzumab.
ANC less than 1,000 mm^3 and/or platelet count[a] less than 50,000/mm^3 before inotuzumab treatment	If ANC or platelet count decreases, then interrupt the next cycle of treatment until at least one of the following occurs: • ANC and platelet counts recover to at least baseline levels for the previous cycle OR • ANC recovers to 1,000/mm^3 or greater and platelet count recovers to 50,000/mm^3 or greater OR • Stable or improved disease (based on most recent bone marrow assessment) and the ANC and platelet count decrease is considered to result from the underlying disease (not considered to be inotuzumab-related toxicity).

[a] Platelet count used for dosing should be independent of blood transfusion.

Inotuzumab Ozogamicin Dose Modifications for Nonhematologic Toxicities	
Nonhematologic Toxicity	**Inotuzumab Dose Modification(s)**
Veno-occlusive disease (VOD) or other severe liver toxicity	Permanently discontinue treatment.
Total bilirubin greater than 1.5 × ULN and AST/ALT greater than 2.5 × ULN	Interrupt dosing until recovery of total bilirubin to 1.5 × ULN or less and AST/ALT to 2.5 × ULN or less before each dose unless due to Gilbert's syndrome or hemolysis. Permanently discontinue treatment if total bilirubin does not recover to 1.5 × ULN or less or AST/ALT does not recover to 2.5 × ULN or less.
Infusion-related reaction	Interrupt the infusion and institute appropriate medical management. Depending on the severity of the infusion-related reaction, consider discontinuation of the infusion or administration of steroids and antihistamines. For severe or life-threatening infusion reactions, permanently discontinue treatment.
Nonhematologic toxicity Grade 2[a] or greater	Interrupt treatment until recovery to Grade 1 or pretreatment grade levels before each dose.

[a]Severity grade according to National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE).

Inotuzumab Ozogamicin Dose Modifications Depending on Duration of Dosing Interruption Due to Nonhematologic Toxicities	
Duration of Dose Interruption Due to Toxicity	**Inotuzumab Dose Modification(s)**
Fewer than 7 days (within a cycle)	Interrupt the next dose (maintain a minimum of 6 days between doses).
7 days or more	Omit the next dose within the cycle.
14 days or more	Once adequate recovery is achieved, decrease the total dose by 25% for the subsequent cycle. If further dose modification is required, then reduce the number of doses to 2 per cycle for subsequent cycles. If a 25% decrease in the total dose followed by a decrease to 2 doses per cycle is not tolerated, then permanently discontinue treatment.
More than 28 days	Consider permanent discontinuation of treatment.

DILUTION

Specific techniques required; see Precautions. Available as 0.9 mg of a lyophilized powder in a single-dose vial for reconstitution and further dilution. Calculate the dose (mg) and number of vials required. Reconstitute each vial with 4 mL of SWFI to obtain a concentration of 0.25 mg/mL. Gently swirl to dissolve. ***Do not shake.*** Solution should be clear to opalescent, colorless to slightly yellow. ***This product is light-sensitive and must be protected from light in all concentrations***. Calculate the required volume of reconstituted solution needed to obtain the correct dose according to the patient's BSA. Remove that calculated volume from an infusion bag of 50 mL NS. Withdraw the calculated volume of reconstituted solution and add it to the infusion container of NS. Total volume will be 50 mL. Gently invert the infusion container to mix the diluted solution. ***Do not shake; protect from light***.

Filters:

Not required. May use polyethersulfone (PES)-, polyvinylidene fluoride (PVDF)-, or hydrophilic polysulfone (HPS)-based filters. Do not use filters made of nylon or mixed cellulose ester (MCE).

Storage:

Store in original carton in refrigerator at 2° to 8° C (36° to 46° F) until time of use. ***Protect original, reconstituted and diluted solutions from light at all times, and do not freeze***. Use reconstituted solution immediately or refrigerate for up to 4 hours. Use diluted solution immediately or store at RT for up to 4 hours or refrigerate for up to 3 hours. If refrigerated, allow diluted solution to equilibrate at RT for 1 hour before administration. Maximum time from reconstitution through the end of administration should be 8 hours or less, with 4 hours or less between reconstitution and dilution. Contains no preservatives; unused portions must be discarded.

COMPATIBILITY

Manufacturer states, “Do not mix or administer as an infusion with other medicinal products.” Do not use filters made of nylon or mixed cellulose ester (MCE). An infusion container made of polyvinyl chloride (PVC) (di-2-ethylhexyl phthalate [DEHP]-containing or non–DEHP-containing), polyolefin (polypropylene and/or polyethylene), or ethylene vinyl acetate (EVA) is recommended.

RATE OF ADMINISTRATION

Infusion lines made of PVC (DEHP-containing or non–DEHP-containing), polyolefin (polypropylene and/or polyethylene), or polybutadiene are recommended.

Administer a single dose equally distributed over 1 hour (50 mL/hr).

ACTIONS

An antineoplastic agent. Inotuzumab ozogamicin is a CD22-directed antibody-drug conjugate (ADC). Inotuzumab recognizes human CD22. The small molecule (*N*-acetyl gamma calicheamicin) is a cytotoxic agent that is covalently attached to the antibody via a linker. Nonclinical data suggest that the anticancer activity of inotuzumab results from binding of the ADC to CD22-expressing tumor cells, followed by internalization of the ADC-CD22 complex and the intracellular release of *N*-acetyl gamma calicheamicin dimethyl hydrazide via hydrolytic cleavage of the linker. Activation of *N*-acetyl gamma calicheamicin dimethyl hydrazide induces double-strand DNA breaks, inducing cell-cycle arrest and apoptotic cell death. 97% bound to human plasma proteins. Metabolized via nonenzymatic reduction. Terminal half-life is approximately 12.3 days.

INDICATIONS AND USES

Treatment of adults with relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL).

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Administered by or under the supervision of a physician experienced in the treatment of acute leukemia and in facilities equipped to monitor the patient and respond to any medical emergency. ■ Hepatotoxicity, including life-threatening and sometimes fatal hepatic veno-occlusive disease (VOD), has been reported during or after treatment or following HSCT after completion of treatment. The risk of VOD (also known as sinusoidal obstruction syndrome) is greater in patients who underwent HSCT after inotuzumab treatment; use of HSCT-conditioning regimens containing two alkylating agents (e.g., busulfan in combination with other alkylating agents) and a total bilirubin level greater than or equal to the ULN before HSCT are significantly associated with an increased risk of VOD. Other risk factors for VOD in patients treated with inotuzumab include ongoing or prior liver disease, prior HSCT, prior VOD, increased age, later salvage lines, and a greater number of inotuzumab treatment cycles. ■ A higher post-HSCT nonrelapse mortality rate has been observed in patients treated with inotuzumab. Most common causes of post-HSCT nonrelapse mortality included VOD and infections. ■ Complications associated with myelosuppression (including infections and bleeding/hemorrhagic events) have been observed. Serious infections, some of which were life threatening, have been reported. Grade 3 or 4 hemorrhagic events, including a fatality, have also been reported. ■ Infusion-related reactions (all Grade 2) were reported. Generally occurred in Cycle 1 shortly after the end of the infusion and resolved spontaneously or with medical management. ■ QT-interval prolongation has been observed. Use caution in patients who have a history of or predisposition to QTc prolongation, are taking medicinal products known to prolong QT interval, or have electrolyte disturbances. ■ Safety and effectiveness in patients with end-stage renal disease with or without hemodialysis is unknown. ■ A protein product; has the potential for immunogenicity. ■ See Dose Adjustments.

Monitor:

Obtain baseline CBC, including differential and platelet counts; repeat before each dose. ■ Obtain baseline liver function studies (alkaline phosphatase, ALT, AST, total bilirubin); repeat before and after each dose. Monitor more frequently in patients who develop abnormal liver tests or have clinical S/S of hepatotoxicity or VOD (e.g., ascites, hepatomegaly, rapid weight gain). Elevations of liver tests may require dosing interruption, dose reduction, or permanent discontinuation of inotuzumab; see Dose Adjustments. ■ For patients who proceed to HSCT, monitor liver tests closely for the first month post-HSCT, then less frequently thereafter according to standard medical practice. ■ Monitor closely for toxicities post-HSCT, including S/S of infection and VOD. ■ Obtain baseline ECG and electrolytes before treatment and monitor periodically as clinically indicated. ■ Monitor for S/S of infusion-related reactions (bronchospasm, chills, dyspnea, fever, hypotension, rash). Monitor vital signs during the infusion and for at least 1 hour after the end of the infusion or until S/S of a possible infusion-related reaction completely resolve. ■ Monitor for S/S of infection, bleeding, hemorrhage, or other effects of myelosuppression; fatalities have been reported; see Dose Adjustments. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Antiemetics may be administered to increase patient comfort. ■ See Precautions and Antidote.

Patient Education:

Avoid pregnancy. Use of effective contraception required in women of reproductive potential and in men with female partners of reproductive potential during inotuzumab treatment and for at least 8 months (women) to 5 months (men) after the last dose; see Maternal/Child. ■ May impair fertility in both men and women. ■ Promptly report infusion-related symptoms (chills, dyspnea, fever, rash), signs of bleeding, infection, or any other unusual or unexpected symptoms or side effects. ■ Promptly report ascites, rapid weight gain, or right upper quadrant pain and tenderness; may indicate liver toxicity. ■ Report S/S of possible QTc prolongation (e.g., dizziness, light-headedness, syncope). ■ See Appendix D.

Maternal/Child:

Avoid pregnancy. Based on its mechanism of action and findings from animal studies, inotuzumab can cause fetal harm. ■ Do not breast-feed during treatment and for at least 2 months after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No differences in responses identified between older and younger patients.

DRUG/LAB INTERACTIONS

Concomitant use with **drugs known to prolong the QT interval or induce torsades de pointes** are numerous and may increase the risk of a clinically significant QTc interval prolongation. Discontinue or use alternative concomitant drugs that do not prolong the QT/QTc interval while using inotuzumab. If concomitant use required, obtain ECG and electrolytes before the start of treatment and after initiation of any drug known to prolong QTc, and periodically monitor as clinically indicated during treatment. Examples of ***some*** drugs that prolong the QT include **anesthetic agents, Class IA antiarrhythmic agents** (e.g., procainamide or quinidine), **Class III antiarrhythmic agents** (e.g., amiodarone [Nexterone], dofetilide [Tikosyn], sotalol [Betapace])**, anticonvulsants, calcium channel blockers, diuretics, fluoroquinolones** (e.g., levofloxacin [Levaquin]), certain **macrolide antibiotics** (e.g., erythromycin [Erythrocin]), **phenothiazines** (e.g., chlorpromazine [Thorazine]), **psychotropics, 5-HT3 antagonists** (e.g., ondansetron [Zofran]), **serotonin reuptake inhibitors,** and **tricyclic antidepressants** (e.g., amitriptyline [Elavil], imipramine [Tofranil]).

SIDE EFFECTS

Abdominal pain, anemia, fatigue, febrile neutropenia, fever, headache, hemorrhage, hyperbilirubinemia, increased gamma-glutamyl transferase and transaminases, infection, leukopenia, nausea, neutropenia, and thrombocytopenia are most common. Ascites; chills; constipation; diarrhea; increased alkaline phosphatase, amylase, and lipase; lymphopenia (including decreased B-lymphocyte count); pancytopenia (including bone marrow failure, febrile bone marrow aplasia, and pancytopenia); stomatitis; tumor lysis syndrome; and vomiting have also been reported. The most serious side effects include hepatotoxicity (including VOD), increased risk of posttransplant nonrelapse mortality, infusion/hypersensitivity reactions, myelosuppression, and QT-interval prolongation.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically. See Usual Dose; infusion-related reactions may be attenuated by premedication with acetaminophen, diphenhydramine, and steroids. Discontinue infusion if S/S of anaphylaxis, clinically significant hypotension, or severe respiratory symptoms occur. Monitor until S/S completely resolve. Manage severe bleeding, hemorrhage, or persistent thrombocytopenia using dose delay or permanent discontinuation of inotuzumab; see Dose Adjustments for management of hematologic and nonhematologic toxicities. Provide supportive care as indicated. Monitor VS and blood counts carefully. Platelet or RBC transfusions and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated. Treat infusion/hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Resuscitate as necessary.

INSULIN HUMAN INJECTION (REGULAR)

(**IN**-sue-lin)
Humulin R, Novolin ge Toronto 🍁 ■ Myxredlin
Hormone
Antidiabetic agent
pH 7 to 7.8

USUAL DOSE

Only regular human insulin is given by IV method.

Dose varies greatly. Individualize dose based on route of administration, patient’s metabolic needs, blood glucose monitoring results, and glycemic control goal. It is imperative that dosing is individualized and adjusted based on blood glucose determinations because of the marked loss of insulin from adsorption to glass and plastic infusion containers and tubing; see Precautions. Several protocols have been published. Review institution-specific protocol if available.

Diabetic ketoacidosis or hyperosmolar hyperglycemic state (unlabeled):

Administer a bolus dose of 0.1 unit/kg (optional) followed by a continuous infusion of

0.1 to 0.14 unit/kg/hr. If serum glucose does not fall by at least 10% in the first hour, administer an IV bolus of 0.14 unit/kg and continue the infusion. In addition, if serum glucose does not fall by 50 to 75 mg/dL in the first hour, increase the insulin infusion rate hourly until a steady glucose decline is achieved. Once the serum glucose reaches 300 mg/dL (diabetes mellitus with hyperosmolar coma) or 200 mg/dL (diabetic ketoacidosis), decrease the infusion rate to 0.02 to 0.05 unit/kg/hr or switch to a subcutaneous insulin regimen.

Hyperkalemia (unlabeled):

Insulin may be used in patients with or without diabetes mellitus to treat hyperkalemia. Must be administered with a dextrose solution in nondiabetic patients. 0.1 unit/kg (not to exceed 10 units) as an IV bolus followed by dextrose 25 Gm IV (50 mL of D5W) over 5 minutes is an example of one regimen in use.

PEDIATRIC DOSE

Diabetic ketoacidosis (unlabeled):

Administer 0.05 to 0.1 unit/kg/hr as a continuous infusion until resolution of ketoacidosis. Transition to a subcutaneous insulin regimen.

Hyperosmolar hyperglycemic state (unlabeled):

Administer 0.025 to 0.05 unit/kg/hr. Titrate infusion rate to achieve a decrease in serum glucose concentration at a rate of 50 to 75 mg/dL/hr.

Hyperkalemia (unlabeled):

Administer 0.1 unit/kg of insulin with 400 mg/kg of glucose; usual ratio of combination therapy of insulin to glucose is 1 unit of insulin for every 4 g of glucose.

DOSE ADJUSTMENTS

Dose adjustments may be needed with changes in physical activity, changes in meal patterns, changes in renal or hepatic function, or during acute illness. ■ A reduced dose of insulin may be indicated when infusions are discontinued and SC administration is indicated; see comments under Usual Dose. ■ Dose requirements may be reduced in patients with renal or hepatic impairment. ■ Dose adjustment may be indicated if it is necessary to change from one insulin product to another. ■ Dose adjustment may be needed when coadministered with certain drugs; see Drug/Lab Interactions.

DILUTION

Regular insulin:

Use only if clear. Dilute with NS to a concentration from 0.1 unit/mL to 1 unit/mL. 100 units of insulin (1 mL) to 100 mL of NS will yield a solution with a final concentration of 1 unit/mL. Also available in a Galaxy premixed single dose container containing 100 units/100 mL of NS (**Myxredlin**).

Storage: Vials:

Store unopened vials in refrigerator. A vial that is in use may be stored at RT for 31 days ***(regular insulin).*** Protect from sunlight and freezing.

Infusions:

Some insulin may be initially adsorbed to the material of the infusion bag. ***Regular insulin:*** Infusion bags prepared as indicated in dilution are stable for 48 hours refrigerated and then may be used at RT for up to an additional 48 hours.

Premixed:

Store in refrigerator in original carton to protect from light until administration. May be stored at RT up to 25° C (77° F) for up to 30 days in original carton. Do not place back in refrigerator Discard after 30 days if stored at RT. Do not freeze and do not use if it has been frozen. Do not shake. Discard any unused portion.

COMPATIBILITY

Do not add supplementary medication or additives.

Other sources suggest specific **compatibilities** for ***regular insulin*** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

When given in an IV infusion, the rate should be ordered by the physician and will depend on insulin and fluid needs; see Dilution for example. If insulin is added with the IV bottle or infusion bag in a hanging position, insulin will rise to the top (stratification). To ensure adequate mixing, repeatedly invert and agitate the container. Decrease rate when blood glucose reaches 200 to 300 mg/dL. Do not use ***Myxredlin*** in a series connection.

ACTIONS

A hormone produced by the pancreas that controls the storage and metabolism of carbohydrates, proteins, and fat. Responsible for regulation of glucose metabolism. Binds to insulin receptors on muscle and fat cells and lowers blood glucose by facilitating cellular uptake of glucose and inhibiting hepatic glucose production. Also inhibits lipolysis, proteolysis, and gluconeogenesis and enhances protein synthesis and conversion of excess glucose into fat. Rapidly and widely distributed. The glucose-lowering activities of regular insulin, insulin aspart, insulin glulisine, and insulin lispro are equipotent when administered by the IV route. The average elimination half-life is dose dependent and ranges from 0.25 to 1 hour depending on dose and product.

INDICATIONS AND USES

Regular insulin:

Treatment of patients with diabetes mellitus to improve glycemic control. Usually used as part of a SC injection regimen or as a SC infusion administered via an external insulin pump. May be given IV. Proper medical supervision is required to prevent hypoglycemia and hypokalemia.

CONTRAINDICATIONS

Contraindicated during episodes of hypoglycemia and in patients hypersensitive to regular human insulin, insulin aspart, insulin glulisine, insulin lispro, or one of the excipients of any of these products.

PRECAUTIONS

Regular insulin:

Concomitant oral antidiabetic treatment may need to be adjusted. ■ Hypoglycemia and hypokalemia are potential side effects of insulin therapy. Use caution in patients in whom these side effects may be clinically relevant (e.g., patients who are fasting, have autonomic neuropathy, are using potassium-lowering drugs [e.g., diuretics], or are taking drugs sensitive to serum potassium levels [e.g., digoxin]). ■ Severe hypoglycemia may lead to unconsciousness and/or convulsions and may result in temporary or permanent impairment of brain function or death. Early warning symptoms of hypoglycemia may be different or less pronounced under certain conditions such as long-standing diabetes, diabetic nerve disease, and the use of medications such as beta-blockers. ■ Untreated hypokalemia may cause respiratory paralysis, ventricular arrhythmia, and death. ■ Use with caution in patients with renal or hepatic impairment; may be at a higher risk of hypoglycemia; see Dose Adjustments. Frequent monitoring may be required. ■ Insulin requirements may be altered during illness or stress. ■ Anti-insulin antibodies have been reported. Clinical significance of anti-insulin antibodies is unknown. ■ Systemic hypersensitivity reactions have been reported. May include hypotension, pruritus, rash, shortness of breath, sweating, tachycardia, and/or wheezing. Anaphylaxis has occurred. ■ See Drug/Lab Interactions.

Regular insulin:

Insulin potency may be reduced by at least 20% and possibly up to 80% via the glass or plastic infusion container and plastic IV tubing before it actually reaches the venous system when given by infusion. The percentage adsorbed is inversely proportional to the concentration of insulin (the larger the dose, the less adsorption) and takes place within 30 to 60 minutes. Albumin is sometimes added to reduce this adsorption. Other additives (e.g., electrolytes, other drugs, vitamins) may also reduce adsorption. Other methods of compensation for insulin loss include the addition of added insulin to saturate binding sites or the use of a syringe pump (instead of infusion containers) to reduce surface area for adsorption.

Monitor:

Depending on indication for use, response to insulin may be measured by blood glucose, blood pH, ketones, BUN, SCr, fluid status, sodium, potassium, chloride, osmolality, anion gap, and mental status. Monitor patient carefully in all situations. ■ Glucose and potassium levels must be monitored closely during IV administration of insulin to avoid potentially fatal hypoglycemia and hypokalemia. ■ Glycosylated hemoglobin (HgbA1c) may be measured to assess long-term glycemic control. ■ See Drug/Lab Interactions.

Patient Education:

Monitor blood glucose as directed. ■ Adhere to consistent diet and exercise programs. ■ Avoid alcohol. ■ Review medications or changes in medication regimen with a health care professional. ■ Review S/S of hypoglycemia and hyperglycemia with a health care professional. Be familiar with the treatment for each. ■ Insulin requirements may change with onset of illness. Monitor glucose carefully and adjust insulin therapy as required.

Maternal/Child:

Regular insulin:

Insulin therapy is the preferred treatment of type 1 and type 2 diabetes during pregnancy. Regular insulin is used IV for glycemic control during labor. Poorly controlled diabetes in pregnancy increases the maternal risk for diabetic ketoacidosis, pre-eclampsia, spontaneous abortions, preterm delivery, stillbirth, and delivery complications. Poorly controlled diabetes increases the fetal risk for major birth defects, stillbirth, and macrosomia-related morbidity. Monitor carefully; insulin requirements may change at different stages of pregnancy and may drop immediately postpartum. ■ Use caution in breast-feeding. ■ Breast-feeding may decrease insulin requirements. ■ Inadequately controlled maternal blood glucose late in pregnancy may cause increased insulin production in the fetus. Monitor and treat neonatal hypoglycemia postpartum.

Elderly:

No overall differences in safety or effectiveness were observed between elderly patients and younger patients. Elderly patients may be at increased risk of hypoglycemia due to comorbid conditions and concomitantly administered medications; see Dose Adjustments and Drug/Lab Interactions. Initial dosing, dose increments, and maintenance dosage should be conservative to avoid hypoglycemia.

DRUG/LAB INTERACTIONS

Hypoglycemic effect may be potentiated by **ACE inhibitors, anabolic steroids, angiotensin II receptor–blocking agents, disopyramide, fluoxetine, fibrates, guanethidine, MAO inhibitors, oral antidiabetic agents, pentoxifylline, salicylates, sulfonamides, and many others**. Dose adjustment and increased frequency of glucose monitoring may be required with concomitant use. ■ Drugs that may reduce blood glucose–lowering effect include **atypical antipsychotic medications, corticosteroids, danazol, diuretics, estrogen, glucagon, isoniazid** (INH), **niacin, oral contraceptives, phenothiazine derivatives, protease inhibitors, somatropin, sympathomimetic agents, thyroid preparations, and others**. Dose adjustment and increased frequency of glucose monitoring may be required with concomitant use. ■ **Alcohol, beta-adrenergic blockers including ophthalmics, clonidine, and lithium** may either potentiate or inhibit the blood glucose–lowering effect of insulin. Dose adjustment and increased frequency of glucose monitoring may be required with concomitant use. ■ Will affect serum potassium levels; use caution in patients taking **digoxin.** ■ **Octreotide** may alter insulin, glucagon, and growth hormone secretion, resulting in hypoglycemia or hyperglycemia. Monitor serum glucose and adjust insulin dose as indicated. ■ **Pentamidine** is toxic to the beta cells of the pancreas. Patients may develop hypoglycemia initially as insulin is released. This may be followed by hypoinsulinemia and hyperglycemia with continued pentamidine therapy. ■ S/S of hypoglycemia may be masked in the presence of **beta-blockers, clonidine, guanethidine, and reserpine**. Increased frequency of glucose monitoring may be required with concomitant use. ■ **Thiazolidinediones** (TZDs) can cause dose-related fluid retention, particularly when used in combination with insulin. Fluid retention may lead to or exacerbate heart failure. Patients receiving concomitant therapy should be monitored for S/S of heart failure. Dose reduction or discontinuation of the TZD may be indicated if heart failure develops.

SIDE EFFECTS

The most common adverse reactions with IV administration of insulin include hypersensitivity reactions, hypoglycemia, pruritus, and rash. Other commonly reported reactions are hypokalemia, injection site reactions, peripheral edema, and weight gain. Additional side effects reported in studies include abdominal pain, arthralgia, asthenia, back pain, chest pain, diarrhea, dysmenorrhea, fever, headache, hypertension, hyporeflexia, influenza, myalgia, nasopharyngitis, nausea, onychomycosis, pain, sensory disturbances, sinusitis, skin disorders, upper respiratory infections, and urinary tract infections. Severe hypersensitivity reactions may include anaphylaxis, angioedema, bronchospasm, generalized skin reactions, rash, hypotension, and shock.

Overdose:

Severe hypoglycemia and hypokalemia. Severe hypoglycemia may result in coma, seizures, or neurologic impairment. Severe, untreated hypokalemia may lead to respiratory paralysis, ventricular arrhythmia, and death.

ANTIDOTE

Discontinue the drug immediately and notify physician of adverse reactions or hypoglycemia. ***Glucagon*** 1 to 2 mg IM or SC is the specific antidote for insulin overdose. It may be supplemented by dextrose 50% IV. Oral carbohydrates such as glucose tablets or gel or orange juice may be sufficient to combat early symptoms of mild hypoglycemia. Correct hypokalemia as indicated. Hypersensitivity reactions usually respond to symptomatic treatment.

INTERFERON ALFA-2b, RECOMBINANT BBW

(in-ter-**FEER**-on **AL**-fah)
Intron A
Biologic response modifier
Antineoplastic
pH 6.9 to 7.5

USUAL DOSE (International units [IU])

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

Acetaminophen may lessen flu-like side effects. To enhance tolerability, injections should be administered in the evening when possible. ***Not all dosage forms and strengths are appropriate for some indications; see Dilution.***

Malignant melanoma:

Induction: 20,000,000 IU/M² as an infusion for 5 consecutive days per week for 4 weeks. Begin therapy within 56 days of surgical resection.

Maintenance:

Follow with 10,000,000 IU/M² as a SC injection three times each week for 48 weeks. Total treatment regimen lasts for 1 year and should be completed unless there is progression of disease or the drug is discontinued because of specific side effects.

DOSE ADJUSTMENTS

Moderate to severe adverse events may require modification of the dosage regimen or, in some cases, termination of therapy. Temporarily discontinued for serious adverse reactions, if granulocytes decrease to less than 500/mm³, or if ALT/AST increases to 5 to 10 times the ULN. When adverse reactions subside or improvement of granulocytes or liver function tests occurs, treatment can be restarted at 50% of the previous dose. Discontinue permanently if serious adverse reactions persist, if a severe adverse reaction recurs at a reduced dose, if granulocytes decrease to less than 250/mm³, if platelet counts decrease to less than 25,000/mm³, or if ALT/AST increases to more than 10 times the upper limit of normal. ■ See Elderly.

DILUTION (International units [IU])

Intron A Solution for Injection is NOT recommended for IV administration and should not be used for the induction phase of malignant melanoma. Only the sterile powder is suitable for dilution for IV use. Do not use different brands of interferon in any single treatment regimen; variations exist and may adversely affect dosage and response to treatment. Powder for Injection is available in 10, 18, and 50 million IU vials; select one most appropriate for desired dose. Allow product to come to RT before use. Reconstitute immediately before use with 1 mL of SWFI (provided). (The SWFI supplied by the manufacturer contains 5 mL. Discard remaining 4 mL.) Gently swirl to dissolve. Withdraw desired dose and inject into 100 mL of NS. Final concentration should be at least 10 million IU/100 mL.

Storage:

Unopened vials of powder for injection should be refrigerated. After reconstitution, solution should be used immediately but can be refrigerated at 2° to 8° C (36° to 46° F) for 24 hours. Single-dose vial. Discard any unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. One source indicates **compatibility** with NS, LR, and R solutions and **incompatibility** with dextrose solutions.

RATE OF ADMINISTRATION

A single dose equally distributed over 20 minutes. Administration at bedtime and the use of acetaminophen may prevent or partially reduce common side effects (e.g., fever, headache, “flu-like” symptoms).

ACTIONS

A naturally occurring small protein and glycoprotein of the interferon family produced by recombinant DNA techniques. It binds to specific membrane receptors on the cell surface and initiates a complex sequence of intracellular events (e.g., induction of specific enzymes, suppression of cell proliferation, immunomodulating activities [e.g., enhancement of phagocytic activity of macrophages, augmentation of the specific cytotoxicity of lymphocytes for target cells, inhibition of virus replication in virus-infected cells]). Peak concentration achieved within 30 minutes. Half-life about 2 hours; undetectable 4 hours after infusion. The kidney may be the site of interferon catabolism. Has produced a significant increase in relapse-free and overall survival in patients with malignant melanoma.

INDICATIONS AND USES

Adjuvant to surgical treatment in patients with malignant melanoma who are free of disease but at high risk for systemic recurrence within 56 days of surgery. ■ Used IM or SC to treat hairy cell leukemia, follicular non-Hodgkin lymphoma, AIDS-related Kaposi’s sarcoma, chronic hepatitis B, chronic hepatitis C, and intralesionally to treat condylomata acuminata.

CONTRAINDICATIONS

Hypersensitivity to interferon alfa or any of its components. ■ Decompensated liver disease or autoimmune hepatitis.

PRECAUTIONS

May cause or aggravate life-threatening or fatal neuropsychiatric (e.g., depression, aggressive and/or suicidal behavior), autoimmune, ischemic, or infectious disorders. Close monitoring with periodic clinical and laboratory evaluations required. Discontinue therapy if S/S of any of the previous conditions are persistently severe or worsen. Symptoms resolve in most cases. ■ Because of fever and other flu-like symptoms associated with its use, interferon alfa should be used cautiously in patients with a history of pulmonary disease (e.g., COPD), diabetes mellitus prone to ketoacidosis, coagulation disorders (e.g., thrombophlebitis, pulmonary embolism), or severe myelosuppression. ■ Use cautiously in patients with a history of cardiovascular disease (e.g., unstable angina, recent MI, and previous or current arrhythmic disorder).

Cardiovascular adverse events (e.g., arrhythmia, cardiomyopathy, hypotension, MI, tachycardia) have been reported. Supraventricular arrhythmias occurred rarely and appeared to be correlated with pre-existing conditions or prior therapy with cardiotoxic agents. ■ Depression and suicidal behavior (including suicidal ideation, suicidal attempts, and completed suicides), homicidal ideation, and aggressive behavior sometimes directed toward others have been reported; see Monitor and Maternal/Child. ■ Use with caution in patients with a history of psychiatric disorders and in patients with substance use disorders. Drug screening and periodic health evaluation, including psychiatric symptom monitoring, may be indicated. ■ Severe cytopenias, including rare cases of aplastic anemia, have been reported; see Monitor. ■ Ophthalmologic disorders (e.g., decrease or loss of vision; retinopathy, including macular edema, retinal artery or vein thrombosis, retinal hemorrhage, and cotton wool spots; optic neuritis; papilledema; and serous retinal detachment) may be induced or aggravated by treatment with interferons; see Monitor. ■ Use caution in patients with psoriasis and sarcoidosis; may exacerbate disease. ■ Rare cases of autoimmune diseases (e.g., lupus erythematosus, Raynaud's phenomenon, rhabdomyolysis, rheumatoid arthritis, thrombocytopenia, and vasculitis) have been reported; may require discontinuation of therapy. ■ Serum neutralizing antibodies have been detected in some patients; clinical significance unknown. ■ Ischemic and hemorrhagic cerebrovascular events have been reported. A causal relationship between interferon therapy and these side effects is difficult to establish. ■ Endocrine disorders (e.g., hypothyroidism, hyperthyroidism, diabetes mellitus) have developed in patients receiving interferon alfa-2b. ■ Hepatotoxicity, including fatality, has been reported. Interferon alfa increases the risk of hepatic decompensation and death in patients with cirrhosis. ■ Pulmonary disorders (e.g., dyspnea, pulmonary infiltrates, pneumonia, bronchiolitis obliterans, interstitial pneumonitis, pulmonary hypertension, and sarcoidosis), some resulting in respiratory failure and/or patient deaths, may be induced or aggravated by interferons. Recurrence of respiratory failure has been observed with interferon rechallenge. ■ Acute serious hypersensitivity reactions have been reported. ■ Elevated triglyceride levels have been observed. Hypertriglyceridemia may result in pancreatitis.

Monitor:

Obtain baseline CBC including differential and platelet count, blood chemistries (electrolytes, glucose, liver function tests, and TSH), and chest x-ray. Obtain baseline eye exam for all patients and periodically for patients with pre-existing ophthalmologic disorders (e.g., diabetic or hypertensive retinopathy). Obtain baseline ECG if there is a history of cardiovascular disease and/or patient is in advanced stages of cancer. Monitor all tests periodically during therapy. Adjust or discontinue therapy as appropriate. ■ In patients with malignant melanoma, monitor CBC with differential and platelet count and liver function tests weekly during the induction phase and monthly during maintenance. Dose adjustments will be determined by results. Discontinue therapy if neutrophil count drops below 500 cells/mm^3. ■ Hepatic function should be monitored in all patients receiving interferon. Obtain serum bilirubin, ALT, AST, alkaline phosphatase, and LDH at 2, 8, and 12 weeks following initiation of therapy and then every 6 months while on therapy. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Discontinue therapy if platelet count drops below 25,000/mm^3. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, angioedema, bronchoconstriction, urticaria). ■ Closely monitor any patient with a history of cardiovascular disease (see Precautions); arrhythmias (including supraventricular arrhythmias and tachycardia), hypotension, and transient reversible cardiomyopathy have occurred. ■ Hypotension may occur during administration or up to 2 days after therapy; monitor BP frequently. May require fluid replacement to maintain intravascular volume. ■ Maintain adequate hydration, particularly during initial stages of treatment. ■ Monitor for signs of depression and/or aggressive or suicidal behavior. If psychiatric problems develop, patients should be carefully monitored during treatment and in the 6-month follow-up period. If psychiatric symptoms persist or worsen or if suicidal or homicidal ideation or aggressive behavior toward others is identified, treatment with interferon alpha should be discontinued. The patient should be followed closely, with psychiatric intervention as appropriate. Use of narcotics, hypnotics, or sedatives may be required to manage adverse effects; use with caution and monitor carefully. ■ Monitor thyroid function, liver function tests, blood glucose, and triglyceride levels; abnormalities not normalized by medication may require discontinuing interferon. ■ Determine cause of persistent fever (not thought to be due to the flu-like syndrome commonly reported in patients treated with interferon alfa). ■ Repeat chest x-ray if cough, dyspnea, fever, or other respiratory symptoms occur. Monitor closely if pulmonary infiltrates or evidence of pulmonary function impairment is present; may require discontinuing interferon. ■ Obtain an eye exam for any patient who complains of changes in visual acuity, visual fields, or other ophthalmologic symptoms. ■ See Precautions.

Patient Education:

Cooperation for close monitoring and prompt reporting of side effects is imperative. Side effects may include depression (including suicidal ideation), cardiovascular toxicity (e.g., chest pain), ophthalmologic toxicity (e.g., loss of or change in vision), pancreatitis (abdominal pain), cytopenias (persistently high fevers, bruising). ■ Review manufacturer's medication guide before each dose. ■ Home use may require extensive patient education. Review Instructions for Use provided by manufacturer. ■ Do not change brands of interferon without medical consultation. Variations in dosage, routes of administration, and adverse reactions exist among different brands. ■ Do not drive or operate machinery; mental alertness may be impaired. ■ Administration at bedtime and/or use of acetaminophen may be helpful to prevent the most common flu-like side effects. Remain well hydrated. ■ Side effects may decrease in severity as treatment continues. ■ See Appendix D.

Maternal/Child:

Has been shown to have abortifacient effects in monkeys. Should be used only if benefits justify risks. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age for indications other than chronic hepatitis B or C has not been established. ■ Suicidal ideation or attempts have occurred more often among pediatric patients (primarily adolescents) compared with adult patients.

Elderly:

Incidence of encephalopathy, obtundation, and coma has occurred, especially at higher doses. ■ Cardiovascular adverse events and confusion have been reported more frequently in the elderly. ■ Consider age-related decreases in organ function and concomitant disease and drug therapy. Careful monitoring required. Make dose adjustments based on symptoms and/or lab abnormalities.

DRUG/LAB INTERACTIONS

Specific information not available. Use caution with any **other potentially myelosuppressive agent** (e.g., cisplatin, zidovudine [AZT, Retrovir]). ■ May increase serum levels of **theophylline;** monitoring of theophylline levels recommended. ■ See Precautions.

SIDE EFFECTS

Occur in high percentages of patients; may be serious enough to require a decreased dose or discontinuation of drug. Usually rapidly reversible after therapy is discontinued, but may require up to 3 weeks to resolve. The most frequently reported adverse reactions were flu-like symptoms (chills, fatigue, fever, headache, and myalgia). In patients treated for malignant melanoma, the most frequently reported adverse reaction was fatigue. Adverse reactions that were reported in greater than 20% of patients included alopecia, altered taste sensation, anemia, anorexia, chills, depression, diarrhea, dizziness/vertigo, fever, headache, increased AST, myalgia, nausea/vomiting, and neutropenia. Severe adverse reactions (ECOG [Eastern Cooperative Oncology Group] Toxicity Criteria Grade 3 or 4) reported in greater than 10% of patients included chills, fatigue, fever, headache, increased AST, myalgia, and neutropenia/leukopenia. Many other side effects may occur.

Post-Marketing:

Hearing loss, hepatitis B virus reactivation (in HCV/HBV co-infected patients), injection site necrosis, myositis, pericarditis, pulmonary fibrosis, skin disorders (e.g., erythema multiforme, urticaria, Stevens-Johnson syndrome, toxic epidermal necrolysis), tongue pigmentation, and a wide variety of autoimmune and immune-mediated disorders (e.g., idiopathic thrombocytopenic purpura and thrombotic thrombocytopenic purpura) have been identified in post-marketing reports.

ANTIDOTE

Keep physician informed of all side effects. Some will be tolerated or treated symptomatically. Discontinue interferon immediately for any acute serious hypersensitivity reactions and treat as appropriate; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]), and pressor amines (e.g., dopamine). Discontinue drug for any patient who develops severe depression or other psychiatric disorder. Close patient monitoring and psychiatric intervention may be indicated. Discontinue for myelosuppression that persists after dose reduction, endocrine abnormalities or persistently elevated triglycerides associated with symptoms of potential pancreatitis (e.g., abdominal pain, nausea, vomiting) not normalized by medication, serious liver function abnormalities (Grade 3 hepatic injury or hepatic decompensation [Child-Pugh score >6 (Class B and C)]), new or worsening ophthalmologic disorders, serious pulmonary function impairment, or pulmonary infiltrates. Treatment of overdose with hemodialysis or peritoneal dialysis is not considered effective. Resuscitate as necessary.

IPILIMUMAB BBW

(ip-i-**LIM**-ue-mab)
Yervoy
Monoclonal antibody
Antineoplastic
pH 7

USUAL DOSE

Pretreatment:

Baseline clinical chemistries, including liver function tests, adrenocorticotropic (ACTH) level, serum creatinine, and thyroid function tests indicated; see Monitor. Verify pregnancy status.

Unresectable or metastatic melanoma in adult and pediatric patients (12 years of age and older):

3 mg/kg administered as an IV infusion over 90 minutes every 3 weeks for a maximum of 4 doses. In the event of toxicity, doses may be delayed, but all treatment must be administered within 16 weeks of the first dose.

Adjuvant treatment of melanoma in adults:

10 mg/kg as an IV infusion over 90 minutes every 3 weeks for 4 doses followed by 10 mg/kg every 12 weeks for up to 3 years. In the event of toxicity, doses are omitted, not delayed.

Advanced renal cell carcinoma (RCC) in adults:

Nivolumab 3 mg/kg as an IV infusion over 30 minutes, followed by ***ipilimumab*** 1 mg/kg as an IV infusion over 30 minutes on the same day, every 3 weeks for 4 doses. After completing 4 doses of the combination, administer ***nivolumab*** as a single agent (either 240 mg every 2 weeks or 480 mg every 4 weeks) as an IV infusion over 30 minutes until disease progression or unacceptable toxicity. Review the full prescribing information for nivolumab before initiation of this combination treatment.

Microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colon cancer (MCC) in adults and pediatric patients 12 years of age and older:

Nivolumab 3 mg/kg as an IV infusion over 30 minutes, followed by ***ipilimumab*** 1 mg/kg as an IV infusion over 30 minutes on the same day, every 3 weeks for up to 4 doses or until intolerable toxicity or disease progression. After completing 4 doses of the combination, administer ***nivolumab*** 240 mg as a single agent every 2 weeks until disease progression or unacceptable toxicity. Review the full prescribing information for nivolumab before initiation of this combination treatment.

DOSE ADJUSTMENTS

The recommended treatment modifications for immune-mediated adverse reactions to ipilimumab are outlined in the following chart.

Treatment Modifications of Ipilimumab for Immune-Mediated Adverse Reactions

Target/Organ System	Adverse Reaction (CTCAE, v4)	Treatment Modification
Endocrine	Symptomatic endocrinopathy	Withhold ipilimumab. Resume ipilimumab in patients with complete or partial resolution of adverse reactions (Grade 0 or 1) and who are receiving less than 7.5 mg prednisone or equivalent per day.
	• Symptomatic reactions lasting 6 weeks or longer • Inability to reduce corticosteroid dose to 7.5 mg prednisone or equivalent per day	Permanently discontinue ipilimumab.
Ophthalmologic	Grade 2 through 4 reactions • Not improving to Grade 1 within 2 weeks while receiving topical therapy or • Requiring systemic treatment	Permanently discontinue ipilimumab.
All other	Grade 2	Withhold ipilimumab. Resume ipilimumab in patients with complete or partial resolution of adverse reactions (Grade 0 or 1) and who are receiving less than 7.5 mg prednisone or equivalent per day.
	• Grade 2 reactions lasting 6 weeks or longer • Inability to reduce corticosteroid dose to 7.5 mg prednisone or equivalent per day • Grade 3 or 4 reactions	Permanently discontinue ipilimumab.

- Interrupt or slow the rate of infusion in patients with mild or moderate infusion reactions. Permanently discontinue ipilimumab for severe or life-threatening infusion reactions; see Precautions and Antidote. ■ No dose adjustment indicated in renal impairment or mild hepatic impairment. ■ When ipilimumab is administered in combination with nivolumab, if ipilimumab is withheld, nivolumab should also be withheld. See nivolumab prescribing information for recommended nivolumab dose modifications.

DILUTION

Available as a 5 mg/mL solution in 50-mg and 200-mg vials. Solution may have a clear to pale yellow color and may contain translucent-to-white amorphous particles. Discard vial if solution is cloudy or if there is pronounced discoloration. ***Do not shake.*** Allow vials to stand at RT for approximately 5 minutes. Withdraw required volume of ipilimumab and transfer into an infusion bag containing NS or D5W. Final concentration of diluted solution should range from 1 to 2 mg/mL. Mix diluted solution by gentle inversion. For example, a dose for a 70-kg patient with metastatic melanoma would be 70 kg × 3 mg/kg dose = 210 mg. Withdraw 210 mg (42 mL of a 5 mg/mL solution) and transfer to a 100-mL bag of NS or D5W. Final concentration = 210 mg ÷ 142 mL = 1.5 mg/mL. See Compatibility.

Filters:

Administer through a line equipped with a sterile, nonpyrogenic, low–protein binding, in-line filter.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton until time of use to protect from light. Do not freeze or shake. Store diluted solution for no more than 24 hours under refrigeration (2° to 8° C [36° to 46° F]) or at RT. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “Do not mix with, or administer as an infusion with, other medicinal products.” Flush IV line with NS or D5W after each dose. When administered in combination with nivolumab, infuse nivolumab first followed by ipilimumab on the same day. Use separate infusion bags and filters for each infusion.

RATE OF ADMINISTRATION

Interrupt or slow the rate of infusion in patients with mild or moderate infusion reactions.

Ipilimumab (as a single agent):

A single dose equally distributed as an infusion over 90 minutes. Administer through a line equipped with a low–protein binding in-line filter. Flush line with NS or D5W after each dose; see Filters.

Ipilimumab/nivolumab combination:

See Usual Dose. Use separate infusion bags and filters for each infusion. Flush line with

NS or D5W after each dose.

ACTIONS

An IgG1 kappa immunoglobulin. A recombinant, human monoclonal antibody that binds to the cytotoxic, T-lymphocyte–associated antigen 4 (CTLA-4). CTLA-4 is a negative regulator of T-cell activity. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands, CD80/CD86. Blockade has been shown to augment T-cell activation and proliferation, including the activation and proliferation of tumor-infiltrating T-effector cells. Inhibition of CTLA-4 signaling can also reduce T-regulatory cell function, which may contribute to a general increase in T-cell responsiveness, including the antitumor immune response. Terminal half-life is 15.4 days. Renal impairment and mild hepatic impairment did not have a clinically important effect on the pharmacokinetics of ipilimumab.

INDICATIONS AND USES

Treatment of unresectable or metastatic melanoma in adult and pediatric patients (12 years of age and older). ■ Adjuvant treatment of patients with cutaneous melanoma with pathologic involvement of regional lymph nodes of more than 1 mm who have undergone complete resection, including total lymphadenectomy. ■ In combination with nivolumab for the treatment of patients with intermediate or poor risk, previously untreated advanced renal cell carcinoma (RCC). ■ In combination with nivolumab for the treatment of adult and pediatric patients 12 years of age and older with microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer (CRC) that has progressed following treatment with a fluoropyrimidine, oxaliplatin, and irinotecan. This indication is approved under accelerated approval based on overall response rate and duration of response. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

May result in severe and fatal immune-mediated adverse reactions. Reactions may involve any organ system; however, the most common severe immune-mediated adverse reactions are enterocolitis, hepatitis, dermatitis (including toxic epidermal necrolysis), neuropathy, and endocrinopathy. Most reactions are manifested during treatment; however, a minority occurred weeks to months after discontinuation of ipilimumab. In addition to the above, immune-mediated encephalitis, nephritis, pneumonitis, and renal dysfunction have been reported with single ipilimumab dosing and with combination dosing with nivolumab. See manufacturer’s literature for clinical trial information outlining the different clinical courses observed for each of the immune-mediated reactions in single and combination agent therapies. Most, but not all, patients experienced partial or complete resolution of reactions following treatment; see Antidote. ■ When administered in combination with nivolumab, review the nivolumab full prescribing information for serious risks of nivolumab. ■ Cytomegalovirus (CMV) infection/reactivation has occurred with corticosteroid-refractory immune-mediated colitis. If it occurs, consider repeating an infectious workup to exclude alternative etiologies. ■ Severe, life-threatening, or fatal motor or sensory neuropathy, Guillain-Barré syndrome, or myasthenia gravis have been reported. ■ Severe to life-threatening immune-mediated endocrinopathies that require hospitalization or urgent medical intervention or that interfere with activities of daily living have been reported. Endocrinopathies have included hypophysitis, hypopituitarism, adrenal insufficiency, hypogonadism, hypothyroidism, hyperthyroidism, and Cushing's syndrome. ■ Other significant immune-mediated reactions involving other organ systems (e.g., cytopenias, meningitis, myocarditis, nephritis, pancreatitis, pericarditis, uveitis, iritis) have been reported rarely. ■ Severe infusion reactions can occur with nivolumab with ipilimumab; see Dose Adjustments and Rate of Administration. ■ Immune-mediated ocular disease unresponsive to topical immunosuppressive therapy has been reported. ■ Fatal or serious graft-versus-host disease (GVHD) can occur in patients who receive a CTLA-4 receptor blocking antibody (e.g., ipilimumab) either before or after allogeneic hematopoietic stem cell transplantation (HSCT). Consider the benefit versus risk of treatment with a CTLA-4 receptor-blocking antibody after allogeneic HSCT. ■ A small number of patients have tested positive for binding antibodies against ipilimumab. Infusion-related or peri-infusional reactions consistent with hypersensitivity or anaphylaxis were not reported in these patients, and neutralizing antibodies against ipilimumab were not detected. ■ Has not been studied in patients with moderate to severe hepatic impairment. ■ See Drug Interactions.

Monitor:

Obtain baseline clinical chemistries, including liver function tests, serum creatinine, adrenocorticotropic (ACTH) level, and thyroid function tests. Repeat before each dose and as indicated based on symptoms. ■ Assess patients for signs and symptoms of enterocolitis (diarrhea, abdominal pain, mucus or blood in stool, with or without fever) and of GI perforation (peritoneal signs and ileus). In symptomatic patients, rule out infectious etiologies and consider endoscopic evaluation for persistent or severe symptoms. ■ Monitor for CMV infection or reactivation. ■ Monitor for immune-mediated hepatitis (moderate hepatotoxicity: AST or ALT elevations of 2.5 to 5 times the ULN or total bilirubin elevation of more than 1.5 to 3 times the ULN; severe hepatotoxicity: AST or ALT elevations of more than 5 times the ULN or total bilirubin elevations more than 3 times the ULN). In patients with hepatotoxicity, rule out infectious or malignant causes and increase the frequency of liver function test monitoring until resolution of symptoms. ■ Monitor for S/S of immune-mediated pneumonitis. Monitor patients for signs of pneumonitis with radiographic imaging. ■ Monitor for immune-mediated dermatitis (e.g., pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, rash complicated by full-thickness dermal ulceration, or necrotic, bullous, or hemorrhagic manifestations). Unless an alternate etiology has been identified, S/S of dermatitis should be considered immune mediated. ■ Monitor for symptoms of motor or sensory neuropathy (e.g., unilateral or bilateral weakness, sensory alterations, or paresthesia that interferes with daily activities). ■ Monitor for clinical S/S of endocrinopathies, including hypophysitis (inflammation of the pituitary gland), adrenal insufficiency (including adrenal crisis), hyperthyroidism, hypothyroidism, or type 1 diabetes mellitus. Patients may present with fatigue, headache, mental status changes, abdominal pain, unusual bowel habits, and hypotension. Unless an alternate etiology has been identified, S/S of endocrinopathies should be considered immune mediated. ■ Monitor for clinical S/S of immune-mediated ocular disease (blurred vision and reduced visual acuity). ■ Monitor for S/S of immune-mediated encephalitis. Evaluation of patients with neurologic symptoms may include but are not limited to consultation with a neurologist, brain MRI, and lumbar puncture. ■ Monitor for S/S of an infusion-related reaction. ■ Monitor for evidence of GVHD and intervene promptly. ■ See Dose Adjustments, Precautions, and Antidote for treatment of adverse reactions and when to withhold or discontinue treatment.

Patient Education:

Review Medication Guide before each dose and promptly report any side effects noted in this guide. Severe immune-mediated reactions have been reported. ■ May cause fetal harm. Use effective contraception during treatment with ipilimumab and for 3 months after the last dose of ipilimumab. ■ Notify provider of a known or suspected pregnancy. Women who become pregnant during ipilimumab treatment are encouraged to enroll in a Pregnancy Safety Surveillance Study.

Maternal/Child:

Based on animal data; may cause fetal harm. The effects of ipilimumab are likely to be greater during the second and third trimesters of pregnancy. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Discontinue breast-feeding during therapy with ipilimumab and for 3 months following the last dose. ■ Safety and effectiveness for use in pediatric patients 12 years of age and older have been established for treatment of unresectable or metastatic melanoma and for microsatellite instability–high (MSI-H) or mismatch repair deficient (dMMR) metastatic colorectal cancer that has progressed following specific treatment. In this age-group, exposure at a dose of 1 mg/kg or 3 mg/kg in pediatric and adult populations is comparable. Safety and effectiveness for use in pediatric patients 12 years of age and older have not been established for the adjuvant treatment of melanoma or for the treatment of renal cell carcinoma. Safety and effectiveness for use in pediatric patients under 12 years of age have not been established.

Elderly:

No overall differences in safety or efficacy were reported between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Increases in transaminases with or without concomitant increases in total bilirubin have occurred with concurrent administration of ipilimumab with vemurafenib.

SIDE EFFECTS

Ipilimumab as a single agent:

The most common side effects are colitis, diarrhea, fatigue, pruritus, and rash. In addition to these reactions, decreased appetite, fever, headache, insomnia, nausea, vomiting, and weight loss were commonly reported with the 10 mg/kg dose. Severe to fatal immune-mediated reactions include dermatitis, endocrinopathy (adrenal insufficiency, hyperthyroidism, hypopituitarism, primary hypothyroidism), enterocolitis (including intestinal perforation), eosinophilia, hepatotoxicity, meningitis, myocarditis, nephritis, neuropathy, pericarditis, pneumonitis, and uveitis. Reported laboratory abnormalities include decreased hemoglobin and increased alkaline phosphatase, amylase, ALT, AST, bilirubin, creatinine, and lipase. Other reported side effects include acute respiratory distress syndrome, encephalitis, esophagitis, hearing loss, infusion reaction, intestinal ulcer, myositis, ocular myositis, polymyositis, renal failure, sarcoidosis, and urticaria. Other immune-mediated adverse reactions were reported in fewer than 1% of patients; see manufacturer's prescribing information.

Ipilimumab in combination with nivolumab:

The most common side effects are abdominal pain, arthralgia, cough, decreased appetite, diarrhea, dyspnea, fatigue, fever, musculoskeletal pain, nausea, pruritus, rash, and vomiting. Severe side effects were similar to ipilimumab as a single agent but also included type 1 diabetes mellitus (immune-mediated endocrinopathy) and immune-mediated encephalitis. Laboratory abnormalities were similar to that of ipilimumab as a single agent. Additional side effects include anemia, constipation, edema, hyperkalemia, hypocalcemia, hypomagnesemia, and lymphopenia.

Post-Marketing:

Drug reaction with eosinophilia and systemic symptoms (DRESS syndrome); graft-versus-host disease.

ANTIDOTE

Keep physician informed of all side effects. Permanently discontinue ipilimumab and initiate systemic high-dose corticosteroid therapy (e.g., 1 to 2 mg/kg/day of prednisone or equivalent) for severe immune-mediated reactions (e.g., Grades 3 to 4). With improvement to Grade 1 or less, initiate corticosteroid taper and continue to taper over at least 1 month. Consider adding anti-TNF (e.g., infliximab) or other immunosuppressant agents for management of immune-mediated enterocolitis unresponsive to systemic corticosteroids within 3 to 5 days or recurring after symptom improvement. Withhold ipilimumab dosing for moderate enterocolitis; administer antidiarrheal treatment (e.g., loperamide) and, if persistent for more than 1 week, initiate systemic corticosteroids at a dose of 0.5 mg/kg/day of prednisone or the equivalent. Addition of an alternative immunosuppressive agent to the corticosteroid therapy or replacement of the corticosteroid therapy should be considered in corticosteroid-refractory immune-mediated colitis (if other causes are excluded). Mycophenolate may be considered in patients with persistent, severe hepatitis despite high-dose corticosteroids. Withhold ipilimumab dosing in patients with moderate hepatotoxicity, dermatitis, or neuropathy (neuropathy not interfering with daily activities). For mild to moderate dermatitis, such as localized rash and pruritus, treat symptomatically. Administer topical or systemic steroids if no improvement of symptoms within 1 week. Withhold dosing in patients with symptomatic endocrinopathies and consider referral to an endocrinologist. Initiate systemic corticosteroids at a dose of 1 to 2 mg/kg/day of prednisone or equivalent, and initiate appropriate hormone replacement therapy. Administer corticosteroid eye drops to patients who develop uveitis, iritis, or episcleritis. If uveitis occurs in combination with other immune-mediated adverse reactions, consider a Vogt-Koyanagi-Harada–like syndrome. Treatment with systemic steroids to reduce the risk of permanent vision loss may be required. Withhold ipilimumab dosing for moderate to severe S/S of pneumonitis, and administer corticosteroids at a dose of 1 to 2 mg/kg/day prednisone equivalents for moderate (Grade 2) or more severe (Grade 3 or 4) pneumonitis, followed by corticosteroid taper. Permanently discontinue for life-threatening (Grade 4) pneumonitis. Withhold ipilimumab dosing in patients with moderate to severe S/S of immune-mediated nephritis. Administer corticosteroids at a dose of 0.5 to 1 mg/kg/day prednisone equivalents for moderate (Grade 2) or severe (Grade 3) increased serum creatinine. If worsening or no improvement occurs, increase dose of corticosteroids to 1 to 2 mg/kg/day prednisone equivalents. Permanently discontinue for life-threatening (Grade 4) increased serum creatinine. Withhold ipilimumab in patients with new-onset moderate to severe neurologic S/S and evaluate to rule out infections or other causes of moderate to severe neurologic deterioration. If other etiologies are ruled out, administer corticosteroids at 1 to 2 mg/kg/day prednisone equivalents for patients with immune-mediated encephalitis, followed by corticosteroid taper. Permanently discontinue ipilimumab for immune-mediated encephalitis. Resuscitate as necessary.

pH 3 to 3.8 (Camptosar)

USUAL DOSE

Pretreatment:

Both formulations (conventional and ONIVYDE):

Verify pregnancy status.

Conventional Irinotecan

Premedication: Antiemetics:

Dexamethasone 10 mg and a 5-HT3 blocker (e.g., ondansetron [Zofran] or granisetron [Kytril]) should be given on the day of treatment. Begin at least 30 minutes before giving irinotecan. ***Anticholinergic premedication:*** In addition, prophylactic or therapeutic atropine may be indicated in patients experiencing cholinergic symptoms. See Monitor.

First-line treatment of colorectal cancer:

Premedication as described above is recommended. Initiate regimen with the dose of irinotecan over 90 minutes. Follow immediately with the dose of leucovorin calcium (see leucovorin calcium monograph). Follow the leucovorin immediately with the dose of fluorouracil (see fluorouracil monograph). Doses and modified dosing recommendations are outlined in the chart Combination-Agent Dosage Regimens and Dose Modifications. Doses of irinotecan and fluorouracil may require modification based on toxicity.

See the following chart, Combination-Agent Dosage Regimens and Dose Modifications, and see Dose Adjustments, combination therapy, and/or package insert.

Combination-Agent Dosage Regimens and Dose Modifications[a] (Irinotecan/Fluorouracil [5-FU]/Leucovorin Calcium [LV])				
Regimen 1 6-wk cycle with bolus 5-FU/LV (next cycle begins on Day 43)	irinotecan leucovorin 5-FU	125 mg/M^2 IV over 90 min, Day 1, 8, 15, 22 20 mg/M^2 IV bolus, Day 1, 8, 15, 22 500 mg/M^2 IV bolus, Day 1, 8, 15, 22		
		Starting Dose and Modified Dose Levels (mg/M^2)		
		Starting Dose	Dose Level −1	Dose Level −2
	irinotecan	125 mg/M^2	100 mg/M^2	75 mg/M^2
	leucovorin	20 mg/M^2	20 mg/M^2	20 mg/M^2
	5-FU	500 mg/M^2	400 mg/M^2	300 mg/M^2
Regimen 2 6-wk cycle with infusional 5-FU/LV (next cycle begins on Day 43)	irinotecan leucovorin 5-FU bolus 5-FU infusion[b]	180 mg/M^2 IV over 90 min, Day 1, 15, 29 200 mg/M^2 IV over 2 hr, Day 1, 2, 15, 16, 29, 30 400 mg/M^2 IV bolus, Day 1, 2, 15, 16, 29, 30 600 mg/M^2 IV over 22 hr, Day 1, 2, 15, 16, 29, 30		
		Starting Dose and Modified Dose Levels (mg/M^2)		
		Starting Dose	Dose Level −1	Dose Level −2
	irinotecan	180 mg/M^2	150 mg/M^2	120 mg/M^2
	leucovorin	200 mg/M^2	200 mg/M^2	200 mg/M^2
	5-FU bolus	400 mg/M^2	320 mg/M^2	240 mg/M^2
	5-FU infusion[b]	600 mg/M^2	480 mg/M^2	360 mg/M^2

[a] Dose reductions beyond dose level −2 by decrements of ~20% may be warranted for patients continuing to experience toxicity. Provided intolerable toxicity does not develop, treatment with additional cycles may be continued indefinitely as long as patients continue to experience clinical benefit.

[b] Infusion follows bolus administration.

Treatment of colorectal cancer after failure of treatment with fluorouracil: Irinotecan:

Administer as an infusion based on the following chart, Irinotecan Single-Agent Regimens and Dose Modifications. See Premedication. After adequate recovery, additional doses may be repeated in a similar cycle and continued indefinitely in patients who attain a response or in those whose disease remains stable.

Irinotecan Single-Agent Regimens and Dose Modifications			
Weekly Regimen[a]	125 mg/M^2 IV over 90 min, Day 1, 8, 15, 22 then 2-wk rest		
	Starting Dose and Modified Dose Levels (mg/M^2)[c]		
	Starting Dose	Dose Level −1	Dose Level −2
	125 mg/M^2	100 mg/M^2	75 mg/M^2
Once-Every-3-Weeks Regimen[b]	350 mg/M^2 IV over 90 min, once every 3 wks[c]		
	Starting Dose and Modified Dose Levels (mg/M^2)		
	Starting Dose	Dose Level −1	Dose Level −2
	350 mg/M^2	300 mg/M^2	250 mg/M^2

[a] Subsequent doses may be adjusted as high as 150 mg/M^2 or to as low as 50 mg/M^2 in 25 to 50 mg/M^2 decrements depending upon individual patient tolerance.

[b] Subsequent doses may be adjusted as low as 200 mg/M^2 in 50 mg/M^2 decrements depending upon individual patient tolerance.

[c] Provided intolerable toxicity does not develop, treatment with additional cycles may be continued indefinitely as long as patients continue to experience clinical benefit.

Onivyde (Liposomal Irinotecan)

Do not substitute ONIVYDE for other drugs containing irinotecan HCl.

Administer **ONIVYDE before** administering leucovorin and fluorouracil.

Premedication:

Administer a corticosteroid and an antiemetic 30 minutes before the **ONIVYDE** infusion.

Metastatic adenocarcinoma of the pancreas:

70 mg/M^2 as an IV infusion over 90 minutes every 2 weeks. In patients known to be

homozygous for the UGT1A1*28 allele, the recommended starting dose is 50 mg/M^2 as an IV infusion over 90 minutes. Increase dose to 70 mg/M^2 as tolerated in subsequent cycles. In clinical trials, a dose of 70 mg/M^2 **ONIVYDE** was followed by leucovorin 400 mg/M^2 IV over 30 minutes, followed by fluorouracil 2,400 mg/M^2 IV over 46 hours every 2 weeks.

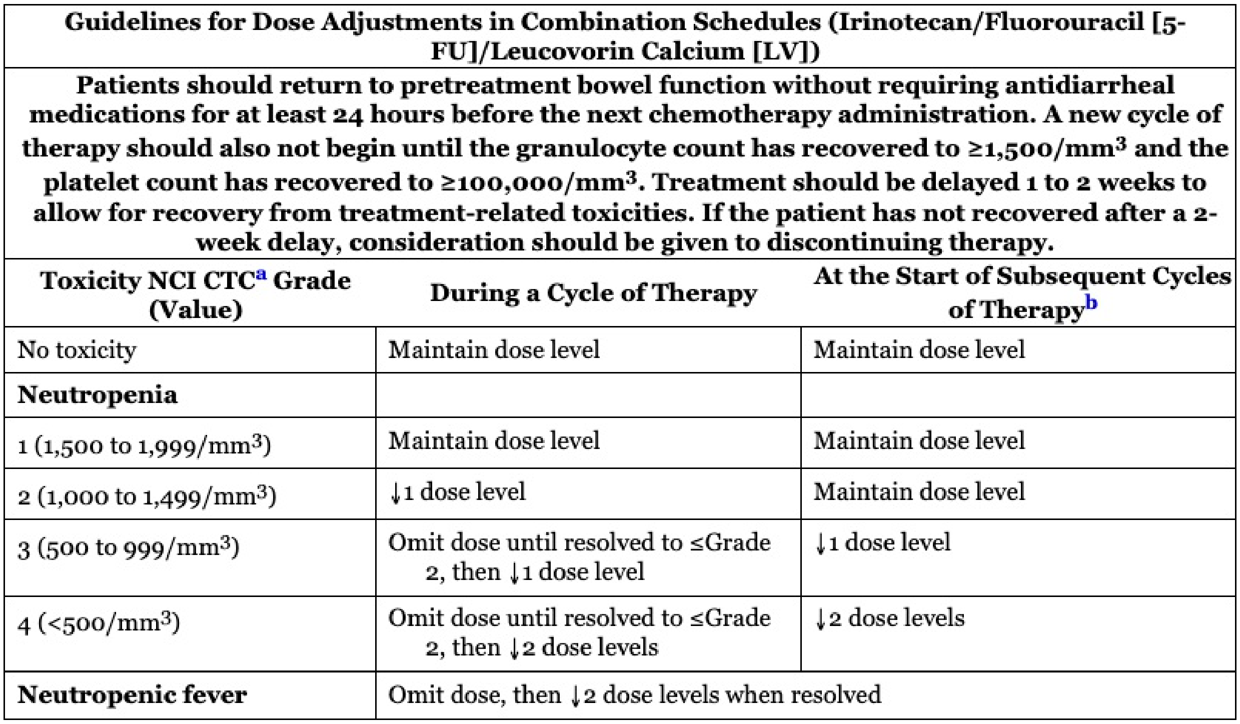
DOSE ADJUSTMENTS

Conventional Irinotecan

A reduction in the starting dose by one dose level may be required in patients with a performance status of 2, in patients who have previously received pelvic/abdominal irradiation, and in patients with increased bilirubin levels; see Elderly. Available information insufficient to recommend a dose for patients with bilirubin greater than 2 mg/dL. ■ Consider decreasing the **starting dose** by at least one level of irinotecan when administered in combination with other agents or as a single agent to a patient known to be homozygous for the UGT1A1*28 allele (an allele is an alternative form of a gene). The precise dose reduction for this patient population is not known. Subsequent dose modification should be based on individual patient tolerance as outlined in the following charts. Heterozygous patients (patients who carry one variant allele) appear to tolerate normal starting doses. ■ See Precautions.

Combination therapy:

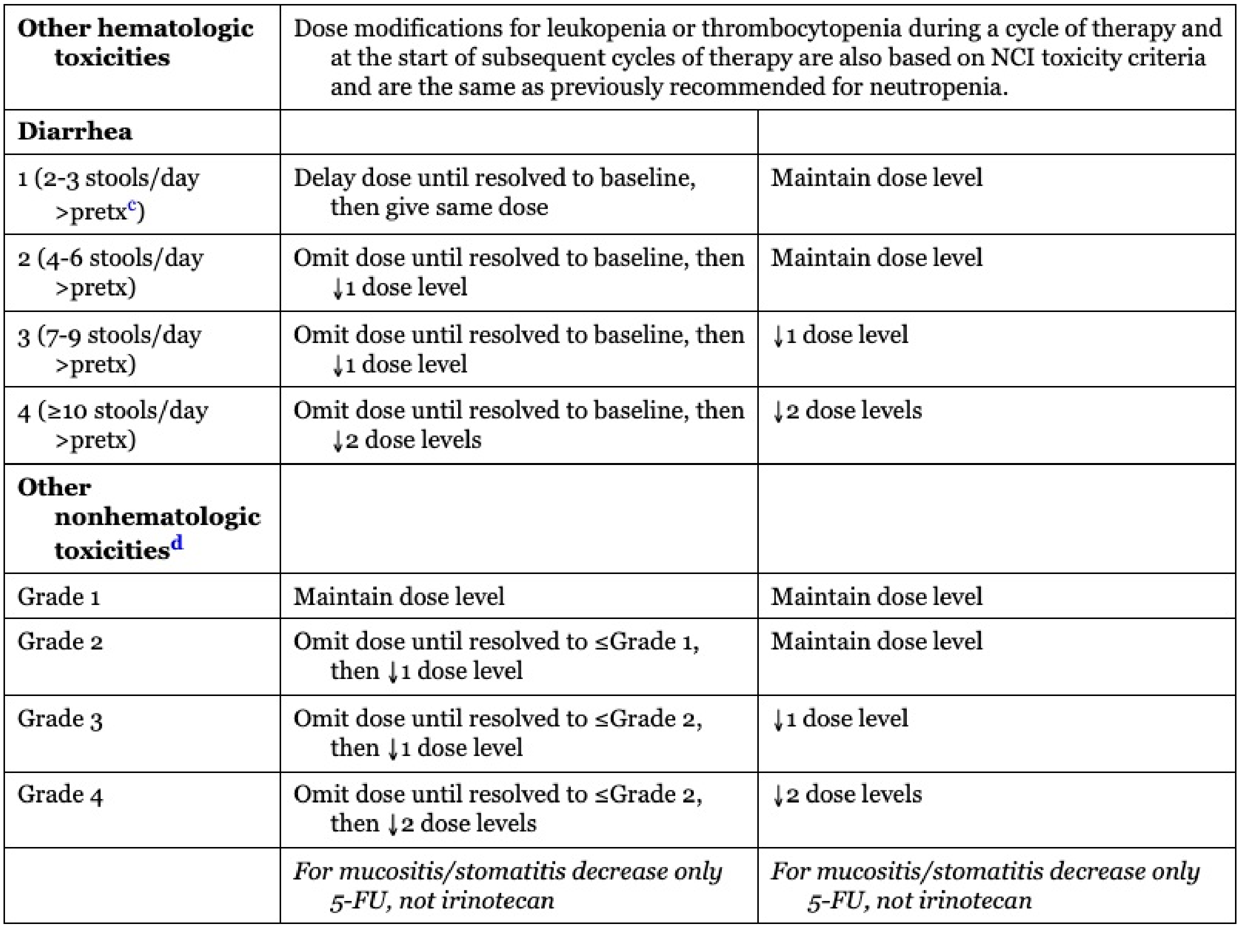
Decrease dose based on toxicity as described in the following chart.



Guidelines for Dose Adjustments in Combination Schedules (Irinotecan/Fluorouracil [5-FU]/Leucovorin Calcium [LV])

Patients should return to pretreatment bowel function without requiring antidiarrheal medications for at least 24 hours before the next chemotherapy administration. A new cycle of therapy should also not begin until the granulocyte count has recovered to ≥1,500/mm^3 and the platelet count has recovered to ≥100,000/mm^3. Treatment should be delayed 1 to 2 weeks to allow for recovery from treatment-related toxicities. If the patient has not recovered after a 2-week delay, consideration should be given to discontinuing therapy.

Toxicity NCI CTC[a] Grade (Value)	During a Cycle of Therapy	At the Start of Subsequent Cycles of Therapy[b]
No toxicity	Maintain dose level	Maintain dose level
Neutropenia		
1 (1,500 to 1,999/mm^3)	Maintain dose level	Maintain dose level
2 (1,000 to 1,499/mm^3)	↓1 dose level	Maintain dose level
3 (500 to 999/mm^3)	Omit dose until resolved to ≤Grade 2, then ↓1 dose level	↓1 dose level
4 (<500/mm^3)	Omit dose until resolved to ≤Grade 2, then ↓2 dose levels	↓2 dose levels
Neutropenic fever	Omit dose, then ↓2 dose levels when resolved	



Other hematologic toxicities	Dose modifications for leukopenia or thrombocytopenia during a cycle of therapy and at the start of subsequent cycles of therapy are also based on NCI toxicity criteria and are the same as previously recommended for neutropenia.	
Diarrhea		
1 (2-3 stools/day >pretx[c])	Delay dose until resolved to baseline, then give same dose	Maintain dose level
2 (4-6 stools/day >pretx)	Omit dose until resolved to baseline, then ↓1 dose level	Maintain dose level
3 (7-9 stools/day >pretx)	Omit dose until resolved to baseline, then ↓1 dose level	↓1 dose level
4 (≥10 stools/day >pretx)	Omit dose until resolved to baseline, then ↓2 dose levels	↓2 dose levels
Other nonhematologic toxicities[d]		
Grade 1	Maintain dose level	Maintain dose level
Grade 2	Omit dose until resolved to ≤Grade 1, then ↓1 dose level	Maintain dose level
Grade 3	Omit dose until resolved to ≤Grade 2, then ↓1 dose level	↓1 dose level
Grade 4	Omit dose until resolved to ≤Grade 2, then ↓2 dose levels	↓2 dose levels
	For mucositis/stomatitis decrease only 5-FU, not irinotecan	*For mucositis/stomatitis decrease only 5-FU, not irinotecan*

[a] National Cancer Institute Common Terminology Criteria (Version 1.0).

[b] Relative to the starting dose of the previous cycle.

[c] Pretreatment.

[d] Excludes alopecia, anorexia, asthenia.

Single-agent therapy:

Reduce dose based on toxicity levels in the following chart, Guidelines for Irinotecan Dose Adjustments in Single-Agent Schedules. The most common reasons for dose reduction are late diarrhea, neutropenia, and leukopenia.

Guidelines for Irinotecan Dose Adjustments in Single-Agent Schedules[a]

A new cycle of therapy should not begin until the granulocyte count has recovered to ≥1,500/mm^3, the platelet count has recovered to ≥100,000/mm^3, and treatment-related diarrhea is fully resolved. Treatment should be delayed 1 to 2 weeks to allow for recovery from treatment-related toxicities. If the patient has not recovered after a 2-week delay, consideration should be given to discontinuing irinotecan.

Worst Toxicity NCI CTC Grade[b] (Value)	**During a Cycle of Therapy**	**At the Start of the Next Cycles of Therapy (After Adequate Recovery). Compared with the Starting Dose in the Previous Cycle[a]**	
	Weekly	**Weekly**	**Once Every 3 Weeks**
No toxicity	Maintain dose level	↓25 mg/M^2 up to a maximum dose of 150 mg/M^2	Maintain dose level
Neutropenia			
1 (1,500 to 1,999/mm^3)	Maintain dose level	Maintain dose level	Maintain dose level
2 (1,000 to 1,499/mm^3)	↓25 mg/M^2	Maintain dose level	Maintain dose level
3 (500 to 999/mm^3)	Omit dose until resolved to ≤Grade 2, then ↓25 mg/M^2	↓25 mg/M^2	↓50 mg/M^2
4 (<500/mm^3)	Omit dose until resolved to ≤Grade 2, then ↓50 mg/M^2	↓50 mg/M^2	↓50 mg/M^2
Neutropenic fever	Omit dose until resolved, then ↓50 mg/M^2	↓50 mg/M^2	↓50 mg/M^2
Other hematologic toxicities	Dose modifications for leukopenia, thrombocytopenia, and anemia during a cycle of therapy and at the start of subsequent cycles of therapy are also based on NCI toxicity criteria and are the same as recommended for neutropenia above.		
Diarrhea			
1 (2-3 stools/day >pretx[c])	Maintain dose level	Maintain dose level	Maintain dose level
2 (4-6 stools/day >pretx)	↓25 mg/M^2	Maintain dose level	Maintain dose level
3 (7-9 stools/day >pretx)	Omit dose until resolved to ≤Grade 2, then ↓25 mg/M^2	↓25 mg/M^2	↓50 mg/M^2
4 (≥10 stools/day >pretx)	Omit dose until resolved to ≤Grade 2, then ↓50 mg/M^2	↓50 mg/M^2	↓50 mg/M^2
Other nonhematologic toxicities[d]			
Grade 1	Maintain dose level	Maintain dose level	Maintain dose level
Grade 2	↓25 mg/M^2	↓25 mg/M^2	↓50 mg/M^2
Grade 3	Omit dose until resolved to ≤Grade 2, then ↓25 mg/M^2	↓25 mg/M^2	↓50 mg/M^2
Grade 4	Omit dose until resolved to ≤Grade 2, then ↓50 mg/M^2	↓50 mg/M^2	↓50 mg/M^2

[a] All dose modifications should be based on the worst preceding toxicity.

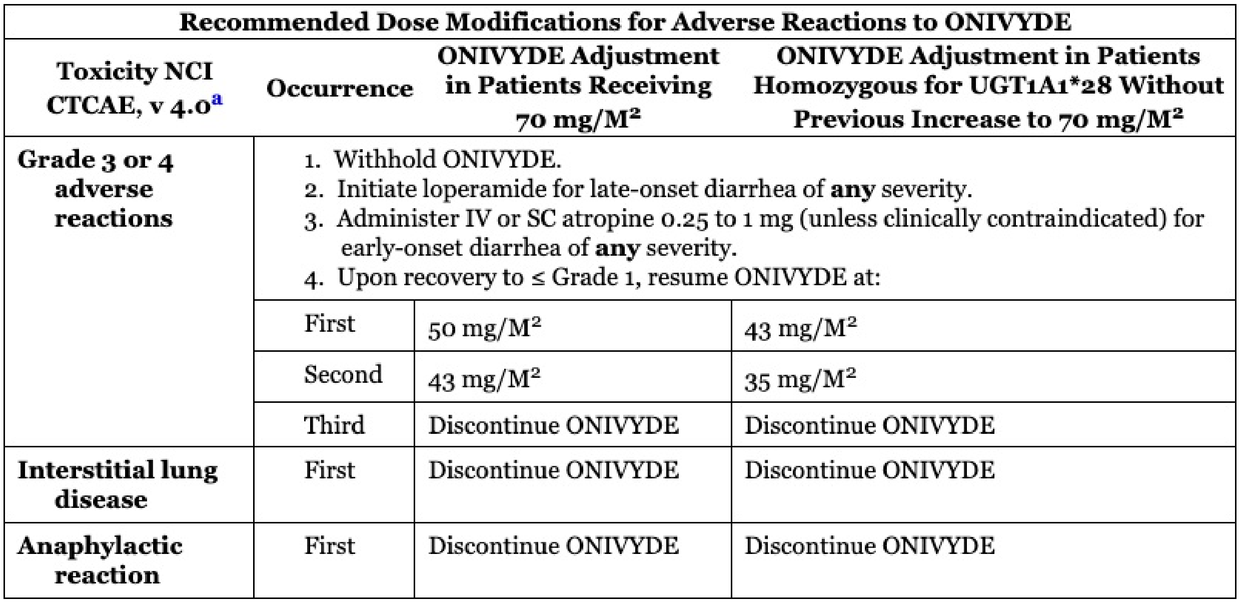
[b] National Cancer Institute Common Terminology Criteria (Version 1.0).

[c] Pretreatment.

[d] Excludes alopecia, anorexia, asthenia.

ONIVYDE

There is no recommended dose of **ONIVYDE** for patients with serum bilirubin above the upper limit of normal. ■ Withhold **ONIVYDE** for an absolute neutrophil count below 1,500/mm^3 or neutropenic fever. ■ Withhold **ONIVYDE** for diarrhea of Grade 2 to 4 severity. ■ See the following chart for dose modifications recommended for adverse reactions.



Recommended Dose Modifications for Adverse Reactions to ONIVYDE

Toxicity NCI CTCAE, v 4.0[a]	Occurrence	ONIVYDE Adjustment in Patients Receiving 70 mg/M^2	ONIVYDE Adjustment in Patients Homozygous for UGT1A1*28 Without Previous Increase to 70 mg/M^2
Grade 3 or 4 adverse reactions	1. Withhold ONIVYDE. 2. Initiate loperamide for late-onset diarrhea of **any** severity. 3. Administer IV or SC atropine 0.25 to 1 mg (unless clinically contraindicated) for early-onset diarrhea of **any** severity. 4. Upon recovery to ≤ Grade 1, resume ONIVYDE at:		
	First	50 mg/M^2	43 mg/M^2
	Second	43 mg/M^2	35 mg/M^2
	Third	Discontinue ONIVYDE	Discontinue ONIVYDE
Interstitial lung disease	First	Discontinue ONIVYDE	Discontinue ONIVYDE
Anaphylactic reaction	First	Discontinue ONIVYDE	Discontinue ONIVYDE

[a] *NCI CTCAE, v 4.0*, National Cancer Institute Common Toxicity Criteria for Adverse Events, Version 4.0.

For recommended dose modifications for fluorouracil (5-FU) and/or leucovorin (LV), refer to their monographs and/or full prescribing information.

DILUTION

Specific techniques required; see Precautions.

Conventional Irinotecan:

Available in single-dose vials in 2-mL, 5-mL, and 15-mL sizes with a concentration of 20 mg/mL. Must be diluted for infusion with D5W (preferred) or NS to concentrations between 0.12 and 2.8 mg/mL. Usually diluted in 250 to 500 mL D5W.

ONIVYDE:

Available in a single-dose vial containing 43 mg irinotecan free base at a concentration of 4.3 mg/mL. It is a slightly yellow, opaque, liposomal dispersion. Withdraw the calculated volume from the vial and dilute in 500 mL D5W or NS. Mix by gentle inversion. Protect diluted solution from light.

Filters:

Conventional irinotecan: Specific information not available. ***ONIVYDE:*** Do not use in-line filters.

Storage:

Conventional irinotecan: Packaged in a blister pack to protect against accidental breakage and leakage. Store in carton protected from light at CRT. When mixed with D5W, is chemically and physically stable for 48 hours if refrigerated and in ambient fluorescent lighting and for 24 hours at CRT. ***Do not refrigerate if mixed with NS;*** a precipitate may form. Stable for 24 hours at CRT when mixed in NS. Because of the risk of microbial contamination, the manufacturer recommends that solutions mixed in D5W or NS be used within 4 hours if kept at RT. However, if reconstitution and dilution are performed under strict aseptic conditions (e.g., on a laminar air flow bench), the solution should be used (i.e., infusion completed) within 12 hours at RT or 24 hours (D5W) if refrigerated. Avoid freezing.

ONIVYDE:

Refrigerate in carton at 2° to 8° C (36° to 46° F) to protect from light. Do not freeze. Administer diluted solution within 4 hours of preparation when stored at RT or within 24 hours if refrigerated. Allow diluted solution to come to RT before administration. Do not freeze. Discard unused portion.

COMPATIBILITY

Conventional Irinotecan

Manufacturer states, “Other drugs should not be added to the infusion solution.”
Other sources suggest a few **compatibilities** based on concentration and manufacturer; consult a pharmacist.

ONIVYDE

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Both formulations:

A single dose as an infusion equally distributed over 90 minutes.

ONIVYDE:

Do not use in-line filter.

ACTIONS

Conventional Irinotecan:

A semi-synthetic derivative of camptothecin. An alkaloid extract from plants such as *Camptotheca acuminata*. A class of antineoplastic agent that inhibits the enzyme topoisomerase I required for DNA replication. Together with its active metabolite SN-38 it causes cell death by damaging DNA produced during the S-phase of the cell cycle. Maximum plasma SN-38 levels are reached within 1 hour of infusion end. Terminal half-life of irinotecan is about 6 to 12 hours; SN-38 is 10 to 20 hours. Irinotecan is moderately bound to plasma proteins (30% to 68%), but SN-38 is highly bound (95%). Metabolic conversion of irinotecan to SN-38 primarily occurs in the liver. SN-38 is conjugated to a glucuronide metabolite by the enzyme UDP-glucuronosyltransferase 1A1 (UGT1A1). Approximately 25% to 50% excreted through bile and urine.

ONIVYDE:

A topoisomerase 1 inhibitor encapsulated in a lipid bilayer vesicle or liposome. Topoisomerase 1 relieves torsional strain in DNA by inducing single-strand breaks. Irinotecan and its active metabolite SN-38 bind reversibly to the topoisomerase 1–DNA complex and prevent re-ligation of the single-strand breaks, leading to cell death. 95% of irinotecan remains liposome-encapsulated. Terminal elimination half-life is approximately 25.8 hours. Protein binding is less than 0.44% of the total irinotecan in ONIVYDE. Metabolism and excretion of irinotecan liposome have not been evaluated.

INDICATIONS AND USES

Conventional Irinotecan:

As a component of first-line therapy in combination with 5-fluorouracil (5-FU) and leucovorin (LV) for patients with metastatic carcinoma of the colon or rectum. ■ For patients with metastatic carcinoma of the colon or rectum whose disease has recurred or progressed following initial fluorouracil-based therapy.

ONIVYDE:

Treatment of patients with metastatic adenocarcinoma of the pancreas after disease progression following gemcitabine-based therapy. Used in combination with fluorouracil and leucovorin.

Limitation of use of ONIVYDE:

Not indicated as a single agent for the treatment of patients with metastatic adenocarcinoma of the pancreas.

CONTRAINDICATIONS

Both formulations:

History of hypersensitivity to conventional or liposomal formulations of irinotecan or any of their components.

PRECAUTIONS

Both formulations:

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Adequate diagnostic and treatment facilities must be available. ■ Can cause severe or life-threatening neutropenia and fatal neutropenic sepsis. ■ Patients who are homozygous for the UGT1A1*28 allele have decreased UGT1A1 enzyme activity. This leads to a higher exposure to SN-38 and an increased risk for neutropenia; see Dose Adjustments. A laboratory test is available to determine the UGT1A1 status of patients. ■ Can cause severe or life-threatening diarrhea that may be either early or late onset (see discussion under individual agents). ■ Severe hypersensitivity reactions, including anaphylaxis, have been reported. ■ Interstitial pulmonary disease has been reported and can be fatal. Use caution in patients with pleural effusions and/or impaired pulmonary function. Risk factors may include pre-existing lung disease or use of pneumotoxic agents (e.g., amiodarone [Nexterone]), radiation therapy, or colony-stimulating factors; see Antidote.

Conventional Irinotecan:

Can induce both early and late forms of diarrhea that appear to be mediated by different mechanisms. Both forms may be severe. Interrupt therapy and reduce subsequent doses if severe diarrhea occurs; see Dose Adjustments. Late diarrhea may be complicated by colitis, ulceration, bleeding, ileus, obstruction, and infection. Cases of megacolon and intestinal perforation have been reported. Patients must not be treated with irinotecan until resolution of any bowel obstruction. ■ May cause severe myelosuppression. Bacterial, viral, and fungal infections have occurred. Deaths due to sepsis following severe neutropenia have been reported. Patients who have previously received pelvic/abdominal irradiation, patients with a baseline serum total bilirubin level of 1 mg/dL or more, or patients with deficient glucuronidation of bilirubin (e.g., patients with Gilbert syndrome) may be at a greater risk of myelosuppression. ■ Hepatic dysfunction may impair the metabolism of both irinotecan and SN-38. Patients with a bilirubin of 1 to 2 mg/dL are at increased risk for developing Grade 3 or 4 neutropenia. The manufacturer does not recommend a dose for patients with a bilirubin greater than 2 mg/dL and states that insufficient information is available to recommend dosing. ■ Use with caution in patients with renal impairment. Has not been studied. Not recommended for use in patients on dialysis. ■ Renal impairment and acute renal failure have been reported; see Monitor. ■ Use caution in elderly patients (may have an increased incidence and severity of diarrhea). ■ Use caution in patients with poor performance status. Patients with a baseline performance status of 2 had higher rates of hospitalization, neutropenic fever, thromboembolism, first-cycle treatment discontinuation, and early deaths than patients with a performance status of 0 or 1. ■ Contains sorbitol. Do not use in patients with hereditary fructose intolerance. ■ The regimen of 5-FU/LV (administered for 4 to 5 days every 28 days) should not be used in combination with irinotecan outside a carefully controlled, well-designed clinical study. Regimen has caused increased toxicity and death. ■ See Monitor.

ONIVYDE:

Severe or life-threatening neutropenia, neutropenic fever or sepsis, and fatal neutropenic sepsis have occurred. The incidence of Grade 3 or 4 neutropenia was higher among Asian patients compared with White patients in clinical trials. Withhold ONIVYDE for absolute neutrophil count below 1,500/mm^3 or neutropenic fever; see Monitor. ■ Severe diarrhea has occurred in patients receiving liposomal irinotecan in combination with fluorouracil and leucovorin. Withhold ONIVYDE for diarrhea of Grade 2 to 4 severity. An individual patient may experience both early- and late-onset diarrhea; see Monitor. ■ Do not administer ONIVYDE to patients with bowel obstruction. ■ Not studied in patients with hepatic impairment. ■ No pharmacokinetic effects noted in patients with mild to moderate renal impairment. Data for severe renal impairment are insufficient.

Monitor:

Both formulations:

Prophylactic antiemetics are recommended; see Usual Dose. To reduce nausea and vomiting and increase patient comfort after initial dosing, additional antiemetics should be available (e.g., prochlorperazine, ondansetron, granisetron). ■ Monitor vital signs. ■ Obtain an accurate bowel history to evaluate changes in bowel habits after administration of irinotecan. ■ Monitor for “early” diarrhea. Occurs during or within

24 hours of irinotecan administration and is cholinergic in nature. Usually transient and only infrequently is severe. May be accompanied by other cholinergic symptoms (e.g., abdominal cramping, bradycardia, diaphoresis, flushing, increased salivation, lacrimation, miosis, rhinitis). Patients who have a cholinergic reaction to irinotecan will probably have similar reactions to subsequent doses. Atropine 0.25 to 1 mg IV or SC may be considered for treatment or for prophylactic use unless clinically contraindicated. ■ Monitor for “late” diarrhea (more than 24 hours after irinotecan administration), which probably results from cytotoxic effects on GI epithelium. May be prolonged; may cause dehydration, electrolyte imbalances, or sepsis; and can be life threatening. At first onset, give loperamide 4 mg; give 2 mg every 2 hours (4 mg every 4 hours during the night) until diarrhea-free for a minimum of 12 hours. Monitor carefully; replace fluids and electrolytes as needed; see Patient Education. ■ Maintain adequate hydration. Orthostatic hypotension or dizziness may indicate dehydration. ■ Initiate antibiotic therapy in patients who develop ileus, fever, or severe neutropenia. ■ Be alert for signs of bone marrow suppression or infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria) or an infusion reaction (e.g., asthenia, chills, fatigue, fever, vomiting). ■ Monitor for S/S of interstitial lung disease. Withhold therapy in patients with new or progressive cough, dyspnea, and fever pending diagnostic evaluation; see Precautions and Antidote. ■ See Dose Adjustments.

Conventional Irinotecan:

Obtain a WBC with differential, hemoglobin, and platelet count before each dose. ■ Obtain baseline electrolytes and liver function tests. Repeat as indicated. ■ Not a vesicant, but monitor injection site for inflammation and/or extravasation. ■ If late-onset diarrhea develops, subsequent weekly chemotherapy treatments should be delayed until pretreatment bowel function has returned for at least 24 hours without the need for antidiarrheal medication. If Grade 2, 3, or 4 late diarrhea recurs, subsequent doses of irinotecan should be decreased; see Dose Adjustments. ■ Avoid use of diuretics and laxatives in patients with diarrhea. ■ Monitor renal function and hydration status. Rare cases of renal impairment or acute renal failure have been reported, usually in patients who became dehydrated from vomiting and/or diarrhea.

ONIVYDE (Liposomal Irinotecan):

Prophylactic antiemetics and corticosteroids are recommended 30 minutes before ONIVYDE infusion. ■ Monitor CBC on Days 1 and 8 of every cycle and more frequently if clinically indicated. Withhold ONIVYDE if the absolute neutrophil count (ANC) is below 1,500/mm^3 or if neutropenic fever occurs. Resume when the ANC is 1,500 mm^3 or above; see Dose Adjustments. ■ Monitor for infusion reactions occurring on the day of administration. S/S have included periorbital edema, pruritus, rash, and urticaria.

Patient Education:

Both formulations: Review patient counseling information. ■ Report any unusual or unexpected symptoms or side effects as soon as possible. ■ Report black or bloody stools, diarrhea not under control within 24 hours, dry mouth, fever or chills, inability to retain oral fluids due to nausea and vomiting, infections, symptoms of dehydration (e.g., light-headedness, dizziness, fainting), urine changes, or vomiting immediately; each must be treated promptly. Have loperamide available. Dose of loperamide prescribed for late diarrhea is higher than the usual dose recommendation. Limit use at this dose to 48 hours to avoid risk of paralytic ileus. ■ May cause dizziness or visual disturbances (usually within 24 hours of administration); use caution in tasks that require alertness. ■ Compliance with regimen imperative (e.g., taking temperature, obtaining lab work, adequate rest, nourishment, and fluids). ■ ***Both formulations:*** Effective birth control required. ***ONIVYDE:*** Advise females of reproductive potential to use effective contraception during treatment and for 1 month after the final dose. Advise males with female partners of reproductive potential to use condoms during treatment and for 4 months after the final dose. ■ Inform health care professionals of any problems with previous treatments. ■ See Appendix D, p. 1311.

Maternal/Child:

Both formulations:

Avoid pregnancy. May cause fetal harm. ■ Discontinue breast-feeding during treatment and for 1 month after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Conventional irinotecan:

Half-life slightly extended. ■ Reduce starting dose by one dose level to 300 mg/M^2 in patients 70 years and older in the single-agent, once-every-3-weeks regimen. No change in the starting dose is recommended for elderly patients receiving the weekly dose schedule of irinotecan. See Usual Dose and Dose Adjustments. ■ Risk of early and late diarrhea increased in the elderly. ■ Monitor carefully; may dehydrate more quickly from diarrhea. Begin loperamide therapy promptly. Avoid laxatives.

ONIVYDE:

No overall differences in safety and effectiveness observed between the elderly and younger patients.

DRUG/LAB INTERACTIONS

Interaction of **conventional irinotecan** and/or **ONIVYDE** with other drugs has not been adequately studied.

Both formulations:

Concomitant use with **CYP3A4 enzyme–inducing anticonvulsants and strong CYP3A4 inducers** may increase the metabolism of irinotecan, which decreases concentrations and effectiveness. Avoid use of **strong CYP3A4 inducers** (e.g., carbamazepine, oxcarbazepine, phenobarbital, phenytoin, rifampin, rifabutin, St. John's wort) if possible. Substitute non–enzyme inducing therapies at least 2 weeks before initiation of irinotecan therapy. ■ **CYP3A4 inhibitors** (e.g., clarithromycin, indinavir, itraconazole, ketoconazole, lopinavir/ritonavir, nefazodone, nelfinavir, ritonavir, saquinavir, telaprevir, voriconazole) **and UGT1A1 inhibitors** (e.g., atazanavir, gemfibrozil, indinavir, ketoconazole) may decrease metabolism, which increases serum concentrations and the risk of toxicity. Avoid the use of **strong CYP3A4 or UGT1A1 inhibitors** if possible. Discontinue at least 1 week before starting irinotecan therapy. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

Conventional irinotecan:

Additive bone marrow suppression may occur with **radiation therapy and/or other bone marrow–suppressing agents** (e.g., azathioprine, chloramphenicol, melphalan). Dose reduction may be required. ■ Concurrent administration with **irradiation** is not recommended. ■ Use caution or withhold **diuretics** (e.g., furosemide) **and laxatives** during treatment; may increase risk of dehydration secondary to vomiting and/or diarrhea.

SIDE EFFECTS

Conventional irinotecan:

Myelosuppression (anemia, leukopenia, neutropenia) and diarrhea ("early" [e.g., abdominal cramping or pain, diaphoresis] or "late") occur in patients and are the most common dose-limiting toxicities with irinotecan administration.

Combination therapy:

Common adverse reactions (greater than 30%) observed in combination therapy are abdominal pain, abnormal bilirubin, alopecia, anemia, anorexia, asthenia, constipation, diarrhea, fever, infection, leukopenia (including lymphocytopenia), mucositis, nausea, neutropenia, pain, thrombocytopenia, and vomiting.

Single-agent therapy:

Common adverse reactions (greater than 30%) observed in single-agent therapy are abdominal pain, alopecia, anemia, anorexia, asthenia, constipation, diarrhea, fever, leukopenia (including lymphocytopenia), nausea, neutropenia, weight loss, and vomiting.

Other reported side effects with irinotecan include abdominal bloating, back pain, chills, confusion, coughing, dehydration, dizziness, dyspepsia, dyspnea, edema, exfoliative dermatitis, flatulence, flushing, headache, hypersensitivity reactions (including anaphylaxis), hyponatremia, hypotension, increased alkaline phosphatase and AST, increased bilirubin, insomnia, interstitial pulmonary disease, muscular contractions or cramps, myocardial infarction, neutropenic fever, neutropenic infection, paresthesia, pneumonia, pulmonary embolism, rash, rhinitis, somnolence, stomatitis, thrombophlebitis, and weight loss may occur. In addition, ileus without preceding colitis has occurred. Renal impairment or failure has occurred, usually in patients who became volume depleted from severe vomiting and/or diarrhea.

ONIVYDE:

Asthenia, decreased appetite, diarrhea, fatigue, fever, lymphopenia, nausea, neutropenia, stomatitis, and vomiting are most common. The most common serious side effects were acute renal failure, dehydration, diarrhea, fever, nausea, neutropenic fever or neutropenic sepsis, pneumonia, sepsis, septic shock, thrombocytopenia, and vomiting. Diarrhea, vomiting, and sepsis were the most common reasons for discontinuing therapy. Anemia, diarrhea, nausea, and neutropenia were the most common reasons for dose reduction.

Post-Marketing:

Asymptomatic elevated pancreatic enzymes (e.g., amylase, lipase), dysarthria (transient), ischemic or ulcerative colitis, megacolon, myocardial ischemic events, pancreatitis.

ANTIDOTE

Keep physician informed of all side effects and monitor carefully. Adjust or omit dose as indicated for toxicity; see Dose Adjustments. Treat diarrhea immediately; see Monitor. In the event of an acute onset of new or progressive, unexplained pulmonary symptoms (e.g., cough, dyspnea, fever), interrupt irinotecan and other coprescribed chemotherapeutic agents pending diagnostic evaluation. If interstitial pulmonary disease is diagnosed, discontinue irinotecan and other chemotherapy and initiate appropriate treatment as needed. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Death may occur from the progression of many side effects. No known antidote for overdose. Maximum supportive care (e.g., to prevent dehydration due to diarrhea and to treat any infectious complications) will help sustain patient in toxicity. If extravasation occurs, flush site with SWFI, elevate the extremity, and apply ice.

IRON DEXTRAN INJECTION BBW

(**EYE**-ern **DEKS**-tran in-**JEK**-shun)
DexFerrum, DexIron 🍁 , InFeD, Infufer 🍁 , Proferdex
Hematinic
Antianemic
Iron supplement
pH 4.5 to 7

USUAL DOSE

Iron-deficiency anemia:

A test dose is required on the first day. The maximum daily dose is 100 mg/day.

Test dose:

0.5 mL (25 mg) on the first day as a test dose. Wait 1 hour. If no adverse reactions, administer the remainder of the initial therapeutic dose of 1.5 mL (75 mg).

Therapeutic dose:

Repeat the total dose of 2 mL (100 mg)/24 hr daily until results achieved or maximum calculated dosage reached (see dosage charts in literature or formula below). A total calculated dose has been given as an infusion. Though not FDA approved, this method is preferred by some to multiple small-dose infusions or injections. To calculate the total amount of iron dextran (mL) required to restore hemoglobin and to replenish iron stores in adults and pediatric patients weighing over 15 kg (lean body weight [LBW]):

$$\text{Dose (mL)} = 0.0442\,(\text{Desired Hb} - \text{Observed Hb}) \times \text{LBW in kg} + (0.26 \times \text{LBW in kg})$$

If actual weight is less than LBW or in pediatric patients between 5 and 15 kg, use actual weight in kg. Calculated dose is in **mL.**

Iron replacement for blood loss:

Dose should represent the equivalent amount of iron represented in blood loss. Begin with a test dose of 0.5 mL (25 mg). Wait 1 hour. If no adverse reactions, calculate the desired dose with the following formula and administer the balance of the replacement dose over 2 to 3 daily doses:

$$\text{Amount of replacement iron (mg)} = \text{Blood loss (mL)} \times \text{Hematocrit}$$

Calculated dose is in **mg;** convert to **mL** before administration.

Formula is based on the approximation that 1 mL of normocytic, normochromic red cells contains 1 mg of elemental iron.

PEDIATRIC DOSE

Injectable iron not normally used in infants under 4 months of age. See Maternal/Child.

Iron-deficiency anemia:

Test dose: 0.5 mL (25 mg) for pediatric patients or 0.25 mL (12.5 mg) for infants over at least 5 minutes on the first day. Wait 1 hour. If no adverse reactions, may give remainder of daily dose. Direct IV push is not recommended; diluting with NS for infusion may lower the incidence of phlebitis. If actual weight is less than LBW or for pediatric patients between 5 and 15 kg, use actual weight in kg. The following daily doses have been recommended for IM injection by one source: ***less than 5 kg,*** 25 mg; ***5 to 10 kg,*** 50 mg; ***more than 10 kg,*** 100 mg. Repeat daily until results achieved or maximum calculated dosage reached (see dosage charts in literature or the formula listed earlier).

Iron replacement for blood loss:

Calculate dose by formula used for adult dose. Dose should represent the equivalent amount of iron represented in blood loss. Begin with a test dose of 0.5 mL (25 mg) for pediatric patients or 0.25 mL (12.5 mg) for infants over at least 5 minutes on the first day. Wait 1 hour. If no adverse reactions, administer the balance of the replacement dose over 2 to 3 daily doses.

DILUTION

Given undiluted, or up to the total desired dose may be further diluted in 50 to 1,000 mL NS for infusion. D5W may cause additional local pain and phlebitis.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT; protect from freezing.

COMPATIBILITY

Manufacturer states, “Do not mix with other medications or add to parenteral nutrition solutions.”

RATE OF ADMINISTRATION

Test dose:

25 mg over 5 minutes (DexFerrum) or over 30 seconds (InFeD). Specific rates of test dose infusions not available for other manufacturers.

IV injection:

If no adverse reactions to the test dose, administer 1 mL (50 mg) or a fraction thereof over 1 minute or more. Extend injection time in pediatric patients.

Infusion:

If no adverse reactions to the test dose, infuse remaining dose over 1 to 8 hours (based on amount of dose, amount of diluent, and patient comfort).

ACTIONS

Iron dextran is removed from the plasma by cells of the reticuloendothelial system, which split the complex into its components of iron and dextran. Iron is immediately bound to protein moieties to form hemosiderin or ferritin, the physiologic forms of iron, or to a lesser extent to transferrin. This iron replenishes hemoglobin and depleted iron stores. Serum ferritin peaks approximately 7 to 9 days after iron dextran administration and slowly returns to baseline after about 3 weeks. Dextran is metabolized or excreted. Negligible amounts of iron are lost via the urinary or alimentary pathways after administration of iron dextran. Some placental transfer of iron dextran may occur. Trace amounts of unmetabolized iron dextran are excreted in breast milk.

INDICATIONS AND USES

Iron deficiency anemia in patients for whom oral administration is unsatisfactory or impossible; identify and treat the cause of the anemia.

Unlabeled uses:

Iron supplementation for patients taking epoetin alfa (Epogen).

CONTRAINDICATIONS

Manifestation of hypersensitivity reactions; any anemia other than iron deficiency.

PRECAUTIONS

Anaphylactic-type reactions, including fatalities, have been reported. Fatal reactions have occurred both after the test dose and in situations in which the test dose was tolerated. Administer in facilities equipped to monitor the patient and respond to any medical emergency. Patients with a history of drug allergy or multiple drug allergies may be at increased risk for anaphylactic-type reactions. Concomitant use of angiotensin-converting enzyme inhibitors may also increase the risk of reactions. Facilities for monitoring the patient and responding to any medical emergency must be readily available. ■ Iron dextran products are not clinically interchangeable. They differ in chemical characteristics and may differ in clinical and adverse effects. ■ Large IV doses have been associated with an increased incidence of side effects, including arthralgia, backache, chills, dizziness, fever, headache, malaise, myalgia, nausea, and vomiting. The onset of these side effects is often delayed (1 to 2 days) and symptoms generally subside within 3 to 4 days. Maximum daily recommended dose is 100 mg (2 mL) of undiluted iron dextran. ■ Use with caution in patients with severe liver impairment, cardiovascular disease, or a history of significant allergies and/or asthma. ■ Do not administer during the acute phase of infectious kidney disease. ■ Patients with rheumatoid arthritis may experience increased joint pain and swelling after administration of iron dextran. ■ Administration of parenteral iron therapy should be limited to patients in whom clinical and laboratory investigations have established an iron-deficient state. Unwarranted therapy may cause excess storage of iron and possible exogenous hemosiderosis.

Monitor:

Keep patient lying down after injection to prevent postural hypotension. ■ Observe continuously for a hypersensitivity reaction during an infusion. Monitor vital signs. ■ Monitor hemoglobin, hematocrit, reticulocyte count, total iron-binding capacity (TIBC), and percent of saturation of transferrin as indicated to monitor therapy and iron status. May take up to 3 weeks to see response. ■ Monitor serum ferritin assays in prolonged therapy. Consider possibility of false results for months after injection caused by delayed utilization. ■ In patients undergoing chronic renal dialysis who are receiving iron dextran complex, the correlation of body iron stores and serum ferritin may not be valid.

Patient Education:

Promptly report S/S of hypersensitivity (e.g., rash, itching, SOB). ■ Promptly report any other side effects, immediate or delayed.

Maternal/Child:

Category C: use only if absolutely necessary in pregnancy, breast-feeding, or childbearing years. ■ Injectable iron not normally used in infants under 4 months of age.

DRUG/LAB INTERACTIONS

Inhibited by **chloramphenicol.** ■ Concurrent administration of medicinal iron with **dimercaprol** will result in the formation of a toxic complex. Either postpone iron therapy or treat severe iron deficiency with transfusions. ■ Effectiveness negated by **deferoxamine**, an iron chelating agent. May be affected by **other chelating agents** (e.g., edetate disodium). Give iron dextran at least 2 hours after a chelating agent. ■ May cause **false serum iron values** within 1 to 2 weeks of large doses of iron dextran. ■ May cause a **false elevated bilirubin, false decreased calcium, or affect numerous other tests or scans.** ■ See Monitor.

SIDE EFFECTS

Backache, dizziness, headache, itching, local phlebitis at injection site, malaise, nausea, rash, shivering, transitory paresthesias.

Major:

Anaphylaxis (fatalities have occurred); arthritic reactivation; dyspnea; febrile episodes; hypotension; leukocytosis; local phlebitis; lymphadenopathy; peripheral vascular flushing, especially with too-rapid injection; tachycardia; urticaria; shock (severe iron toxicity increases vasodilation and venous pooling and decreases circulating blood volume; results in decreased cardiac output, hypotension, increased peripheral vascular resistance, and shock).

Overdose:

Serum iron levels greater than 300 mcg/dL may indicate iron poisoning. Overdose with iron dextran is unlikely. May result in hemosiderosis, and excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as:

Early: Abdominal pain, diarrhea, vomiting.
Late: Bluish-colored lips, fingernails, and palms of hands; acidosis, drowsiness, shallow and rapid breathing, clammy skin, weak and fast heartbeat, hypotension, hypoglycemia, cardiovascular collapse.

ANTIDOTE

Discontinue the drug and notify the physician of early symptoms. For severe symptoms, discontinue drug, treat hypersensitivity reactions, or resuscitate as necessary, and notify physician. Epinephrine and diphenhydramine should always be available. In overdose, monitor CBC, iron studies, vital signs, blood gases, and glucose and electrolytes. Maintain fluid and electrolyte balance. Correct acidosis with sodium bicarbonate. Deferoxamine is an iron chelating agent and may be useful in iron toxicity or overdose. Dialysis will not remove iron alone but will remove the iron deferoxamine complex and is indicated if oliguria or anuria is present.

IRON SUCROSE

(**EYE**-ern **SOO**-kros)
Venofer
Hematinic
Iron supplement
Antianemic
pH 10.5 to 11.1

USUAL DOSE

Dose is expressed in terms of mg of elemental iron. The usual total treatment course of iron sucrose is 1,000 mg. For all indications, treatment may be repeated if iron deficiency recurs.

Adult patients with hemodialysis-dependent chronic kidney disease (HDD-CKD):

100 mg undiluted as a slow IV injection or diluted as a 15-minute infusion during consecutive hemodialysis sessions. Administered early during the dialysis session. Frequency of dosing should be no more than three times weekly.

Adult patients with non–dialysis-dependent chronic kidney disease (NDD-CKD):

200 mg undiluted as a slow IV injection over 2 to 5 minutes or as an infusion of 200 mg in a maximum of 100 mL of NS over 15 minutes. Administer on 5 different days over a 14-day period to a total cumulative dose of 1,000 mg. Alternately, there is limited experience with administering a 500-mg dose on Day 1 and Day 14 as a 3.5- to 4-hour infusion diluted in a maximum of 250 mL of NS.

Adult patients with peritoneal dialysis–dependent chronic kidney disease (PDD-CKD):

300 mg as an infusion on Day 1 and Day 14. Follow with 400 mg as an infusion on Day 28. A total cumulative dose of 1,000 mg given in 3 doses over 28 days. Each infusion is diluted in a maximum of 250 mL NS and administered over 1.5 to 2.5 hours; see Rate of Administration.

PEDIATRIC DOSE

Pediatric patients (2 years of age and older) with hemodialysis-dependent chronic kidney disease (HDD-CKD) for iron maintenance treatment:

The dosing for iron replacement treatment in pediatric patients with HDD-CKD has not been established.

Iron maintenance treatment:

0.5 mg/kg. Do not exceed 100 mg/dose. Administer every 2 weeks for 12 weeks; given undiluted by slow IV injection over 5 minutes or diluted in NS at a concentration of 1 to 2 mg/mL and administered over 5 to 60 minutes. Do not dilute to concentrations below

1 mg/mL. Regimen may be repeated if necessary.

Pediatric patients (2 years of age and older) with non–dialysis-dependent chronic kidney disease (NDD-CKD) or peritoneal dialysis–dependent chronic kidney disease (PDD-CKD) who are undergoing erythropoietin therapy for iron maintenance treatment:

The dosing for iron replacement treatment in pediatric patients with NDD-CKD or PDD-CKD has not been established.

Iron maintenance treatment:

0.5 mg/kg. Do not exceed 100 mg/dose. Administer every 4 weeks for 12 weeks; given undiluted by slow IV injection over 5 minutes or diluted in NS at a concentration of 1 to 2 mg/mL and administered over 5 to 60 minutes. Do not dilute to concentrations below 1 mg/mL. Regimen may be repeated if necessary.

DOSE ADJUSTMENTS

Begin at the low end of the dosing range in elderly patients. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Withhold in patients with evidence of tissue iron overload; see Monitor.

DILUTION

Available in several sizes of single-dose vials. Check vial carefully and select the size that is closest to the desired dose. All contain 20 mg/mL of elemental iron. May be given undiluted or further diluted in NS. Do not dilute to concentrations below 1 mg/mL.

Adult patients with hemodialysis-dependent chronic kidney disease (HDD-CKD):

100-mg dose may be given undiluted or may be further diluted in a maximum of 100 mL of NS and given as an infusion.

Adult patients with non–dialysis dependent chronic kidney disease (NDD-CKD):

200-mg dose may be given undiluted or may be further diluted in a maximum of 100 mL of NS. The 500-mg dose may be further diluted in a maximum of 250 mL of NS and given as an infusion.

Adult patients with peritoneal dialysis–dependent chronic kidney disease (PDD-CKD):

Each 300- or 400-mg dose must be diluted in a maximum of 250 mL NS and given as an infusion.

Pediatric patients receiving iron maintenance treatment:

A single dose may be given undiluted or diluted in NS at a concentration of 1 to 2 mg/mL and given as an infusion. Do not dilute to concentrations below 1 mg/mL; see Usual Dose.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials in original carton at CRT. Do not freeze. Diluted iron infusions should be used immediately after preparation. Discard any unused portion. When diluted with NS to a concentration of 1 to 2 mg/mL in PVC or non-PVC infusion bags, iron sucrose is stable for 7 days at CRT. When undiluted (20 mg/mL) or diluted with NS to a concentration of 2 to 10 mg/mL and stored in a plastic syringe, iron sucrose is stable for 7 days at CRT or refrigerated.

COMPATIBILITY

Manufacturer states, "Do not mix with other medications or add to parenteral nutrition solutions."

RATE OF ADMINISTRATION

Too-rapid administration may cause hypotension or symptoms of overdose; see Side Effects.

Slow IV injection in adults:

A single undiluted dose over 2 to 5 minutes. In dialysis patients, administer into the dialysis line during the dialysis session.

Infusion in adults:

This method of administration may reduce the risk of hypotensive episodes.

Adult hemodialysis-dependent chronic kidney disease patients (HDD-CKD):

A single 100-mg undiluted dose given as a slow IV injection over 2 to 5 minutes. Alternately may be diluted and given as an infusion equally distributed over at least 15 minutes.

Adult non–dialysis dependent chronic kidney disease patients (NDD-CKD):

A single 200-mg undiluted dose as a slow IV injection over 2 to 5 minutes or as an infusion equally distributed over 15 minutes. Has also been administered as an infusion in a 500-mg dose equally distributed over 3.5 to 4 hours.

Adult peritoneal dialysis–dependent chronic kidney disease patients (PDD-CKD):

A single 300-mg dose as an IV infusion equally distributed over 1.5 hours or a single 400-mg dose equally distributed over 2.5 hours.

Pediatric patients receiving iron maintenance treatment:

A single dose as a slow IV injection over 5 minutes or diluted in NS at a concentration of 1 to 2 mg/mL and administered as an infusion over 5 to 60 minutes. Do not dilute to concentrations below 1 mg/mL; see Usual Dose.

ACTIONS

An aqueous complex of polynuclear iron (III)-hydroxide in sucrose. Used to replenish the total body iron stores in patients with iron deficiency. Iron is critical for normal hemoglobin synthesis to maintain oxygen transport and is necessary for various other processes. Following intravenous administration, iron sucrose is dissociated by the reticuloendothelial system into iron and sucrose. Iron distributes into liver, spleen, and bone marrow. Half-life of the iron component is 6 hours. The sucrose component is eliminated mainly by urinary excretion. Most iron is stored in the body. Small amounts are eliminated in the urine. Significant increases in serum iron and ferritin and significant decreases in total iron-binding capacity occur within 4 weeks of beginning iron sucrose treatment.

INDICATIONS AND USES

Treatment of iron deficiency anemia (IDA) in patients with chronic kidney disease (CKD).

CONTRAINDICATIONS

Known hypersensitivity to iron sucrose or any of its inactive components.

PRECAUTIONS

Use only when truly indicated to avoid excess storage of iron. Not recommended for use in patients with iron overload. ■ Potentially fatal hypersensitivity reactions characterized by anaphylactic shock, loss of consciousness, collapse, and/or hypotension (clinically significant) have been reported. Medications and equipment for resuscitation must be readily available. ■ Hypotension has been reported frequently and may be related to rate of administration and/or total dose administered. Follow guidelines for dosing and administration. See Usual Dose and Rate of Administration.

Monitor:

Confirm IV placement and avoid extravasation; injection site discoloration has been reported following extravasation. ■ Monitor vital signs during and immediately following administration. Recumbent position during and after administration may help to prevent postural hypotension. Hypotensive effects may be additive to transient hypotension during dialysis and/or from too-rapid rate of administration. ■ Monitor for S/S of hypersensitivity reactions during and after administration for at least 30 minutes and until clinically stable; see Precautions. Reactions may occur after the first dose or subsequent doses of iron sucrose. ■ Periodic monitoring of hematologic and iron parameters (hemoglobin, hematocrit, serum ferritin and transferrin saturation) is indicated during parenteral iron replacement therapy. Takes about 4 weeks of treatment to see increased serum iron and ferritin and decreased TIBC (total iron-binding capacity) and about 2 to 4 weeks to see an increase in hemoglobin. Transferrin saturation values increase rapidly after IV administration of iron sucrose; wait at least 48 hours after an IV dose to obtain serum iron measurements.

Patient Education:

Review any possible reactions to past parenteral iron therapy. ■ Report S/S of a hypersensitivity reaction promptly.

Maternal/Child:

Use in pregnancy only if clearly needed. Iron deficiency anemia (IDA) during pregnancy should be treated. Untreated IDA has been associated with adverse maternal outcomes such as postpartum anemia and an increased risk for preterm delivery and low birth weight. ■ Safety for use during breast-feeding not established. Use caution and monitor breast-fed infant for GI toxicity (constipation, diarrhea). ■ Safety and effectiveness for iron replacement treatment in pediatric patients with dialysis-dependent or non–dialysis-dependent CKD have not been established. Safety and effectiveness for iron maintenance treatment have been established for pediatric patients with dialysis-dependent or non–dialysis-dependent CKD 2 years of age and older. Has not been studied in patients younger than 2 years of age. ■ Necrotizing enterocolitis in 5 premature infants (weight less than 1,250 Gm) with 2 deaths has been reported in one country in which iron sucrose is approved for use in pediatric patients. No causal relationship to drugs could be established; it may be a complication of prematurity in very-low-birth-weight infants.

Elderly:

Differences in response between elderly and younger patients have not been identified. Lower-end initial doses may be appropriate in the elderly; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Drug interactions involving iron sucrose have not been studied. May reduce the absorption of concomitantly administered **oral iron preparations;** concurrent use not recommended.

SIDE EFFECTS

Adult patients:

Arthralgia, back pain, chest pain, diarrhea, dizziness, headache, hypotension, injection site burning or pain, muscle cramps, nausea, pain in extremity, peripheral edema, pruritus, and vomiting are most common. Other side effects varied according to the type of chronic kidney disease patient who was receiving iron sucrose (e.g., hemodialysis dependent, peritoneal dialysis–dependent, non–dialysis dependent) and included abdominal pain, asthenia, conjunctivitis, cough, dysgeusia, dyspnea, ear pain, feeling abnormal, fluid overload, gout, graft complications, hyperglycemia, hypersensitivity reactions, hypertension, hypoglycemia, injection site extravasation, myalgia, nasal congestion, nasopharyngitis, pharyngitis, sinusitis, upper respiratory tract infection.

Pediatric patients:

Arteriovenous fistula thrombosis, cough, dizziness, fever, headache, hypertension, hypotension, nausea, peritonitis, respiratory tract viral infection, and vomiting occurred.

Overdose:

May result in hemosiderosis. Excess iron may increase susceptibility to infection. If acute toxicity is seen, it may present as abdominal and muscle pain, cardiovascular collapse, dizziness, dyspnea, edema, headache, hemosiderosis, hypotension, joint aches, nausea, pale eyes, paresthesia, sedation, vomiting.

Post-Marketing:

Life-threatening hypersensitivity reactions (e.g., anaphylactic-type reactions, angioedema, bronchospasm, collapse, convulsions, dyspnea, loss of consciousness, shock), back pain, bradycardia, cardiac failure, chromaturia, confusion, dysgeusia, light-headedness, sepsis, sweating, swelling of joints.

ANTIDOTE

Reduce rate of infusion for hypotension or other symptoms. Most symptoms are successfully treated with IV fluids, hydrocortisone sodium succinate, and/or antihistamines. Keep physician informed of all side effects. Discontinue drug if severe hypersensitivity reactions occur. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone), and pressor amines (e.g., dopamine). Resuscitate as needed. Not removed by dialysis.

ISATUXIMAB

(**EYE**-sa-**TUX**-i-mab)
Sarclisa
Antineoplastic agent
Monoclonal antibody (Anti-CD38)

USUAL DOSE

Premedicate with dexamethasone, famotidine, diphenhydramine, and acetaminophen prior to each dose.

Cycle 1:

10 mg/kg on Days 1, 8, 15, and 22 of a 28-day cycle in combination with pomalidomide and dexamethasone or carfilzomib and dexamethasone.

Cycle 2:

10 mg/kg on Days 1 and 15 of a 28-day cycle in combination with combination with pomalidomide and dexamethasone or carfilzomib and dexamethasone. Continue until disease progression or unacceptable toxicity. Available through authorized specialty distributors and specialty pharmacies.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments are necessary.

DILUTION

Calculate required isatuximab dose and dose volume. Remove an amount from a 250-mL NS or D5W infusion bag that is equal to the required volume of isatuximab. Withdraw the necessary isatuximab volume and add to the NS or D5W infusion bag (for a total infusion bag volume of 250 mL). Invert bag gently to mix; ***do not shake***. Infusion bag must be made of polyolefins, polyethylene, polypropylene, polyvinyl chloride (PVC) with di-(2-ethylhexyl)-phthalate (DEHP), or ethyl vinyl acetate (EVA).

Use IV tubing infusion set made of polyethylene, polyvinyl chloride (PVC) with or without di-2-ethylhexyl phthalate (DEHP), polybutadiene, or polyurethane with a 0.22-micron in-line polyethersulfone, polysulfone, or nylon filter.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions.

RATE OF ADMINISTRATION

Administer as an IV infusion. Infusion duration depends on the rate of infusion.

First infusion:

Initiate at 25 mL/hr for 60 minutes; if tolerated, increase rate by 25 mL/hr every 30 minutes to a maximum rate of 150 mL/hr.

Second infusion:

Initiate at 50 mL/hr for 30 minutes; if tolerated, increase rate by 50 mL/hr for 30 minutes, then increase rate by 100 mL/hr to a maximum rate of 200 mL/hr.

Subsequent infusions:

Initiate at 200 mL/hr; maximum rate: 200 mL/hr.

ACTIONS

Isatuximab is an IgG-1–derived monoclonal antibody directed against CD38. It has antitumor activity, cell-mediated cytotoxicity, complement-dependent cytotoxicity, and antibody-dependent cellular phagocytosis and directly inhibits activity of CD38 ectoenzymes.

INDICATIONS AND USES

Multiple myeloma.

CONTRAINDICATIONS

Severe hypersensitivity to isatuximab or any component of the formulation.

PRECAUTIONS

Bone marrow suppression, infusion reactions (including anaphylaxis), secondary malignancy, false-positive indirect Coombs test.

Monitor:

Blood type and screening prior to first dose; consider phenotyping. Screen for hepatitis B.

Patient Education:

Advise patients to call physician if they feel very tired or weak or experience infection, fever, chills, sore throat, sinus pain, increased or a change in sputum production, bleeding, shortness of breath, or signs of allergic reaction.

Maternal/Child:

May cause fetal harm, thus contraindicated. Breast-feeding is not recommended.

Elderly:

Refer to Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

5-ASA, abrocitinib, bacille Calmette-Guérin (BCG) vaccine, baricitnib, brincidofovir, chloramphenicol ophthalmic, cladribine, clozapine, COVID-19 vaccines (may decrease effectiveness), moderate and strong CYP3A4 inducers (may decrease effectiveness of isatuximab; avoid), strong CYP3A4 inhibitors (may increase serum concentration of isatuximab; avoid), deferiprone, denosumab, dipyrone, Echinacea, fexinidazole, fingolimod, inebilzumab, leflunomide, natalizumab, ocrelizumab, ofatumumab, ozanimod, pidotimod, pimecrolimus (avoid), pneumococcal vaccine, polio vaccine (avoid), promazine, rabies vaccine, ropeginterferon alfa 2b, rubella or varicella live vaccines (avoid), sipuleucel-T, tacrolimus topical (avoid), talimogene laherparepvec (avoid), tertomotide, tofacitinib, typhoid vaccine (avoid), upadacitinib (avoid), live vaccines (avoid), varicella virus vaccine (avoid). Inactivated vaccines may have reduced response; give prior to therapy start. Please refer to package insert for further information.

SIDE EFFECTS

Anemia, antibody development, bronchitis, cardiac failure, cough, diarrhea, dyspnea, fatigue, febrile neutropenia, hypertension, infection, infusion-related reactions, lymphocytopenia, malignant neoplasm of skin, nausea, neutropenia, solid tumor, thrombocytopenia, upper respiratory tract infection, vomiting.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

ISAVUCONAZONIUM SULFATE

(eye-sah-vew-koh-nah-**ZOH**-nee-um **SUL**-fayt)
Cresemba
Antifungal
(azole derivative)

USUAL DOSE

Pretreatment:

Obtain specimens for fungal culture and other relevant lab studies (including histopathology) to isolate and identify causative organism(s) before initiating therapy. Institute antifungal therapy and adjust based on results of culture and lab studies. See Maternal/Child.

Loading dose:

372 mg (1 vial) as an infusion every 8 hours for 6 doses.

Maintenance dose:

372 mg (1 vial) as an infusion once daily. Initiate 12 to 24 hours after the last loading dose. Oral formulation (2 capsules = 372 mg) may be substituted when appropriate.

DOSE ADJUSTMENTS

No dose adjustment is required based on age, gender, or race or in patients with mild, moderate, or severe renal impairment, including ESRD. ■ No dose adjustment is required with mild to moderate hepatic impairment.

DILUTION

Available as a lyophilized powder containing 372 mg isavuconazonium sulfate (equivalent to 200 mg isavuconazole). Reconstitute 1 vial with 5 mL of SWFI. Gently shake to dissolve the powder completely. Solution should be clear and free of particulates. Withdraw 5 mL from the reconstituted vial and inject into a 250-mL bag of NS or D5W. Final concentration is approximately 1.5 mg/mL. Diluted solution may have visible translucent to white particulates, which will be removed by in-line filtration. Use gentle mixing or roll bag to minimize the formation of particulates. Avoid unnecessary vibration or vigorous shaking of the solution. Do not use a pneumatic transport system.

Filters:

Must be administered using an infusion set that contains a sterile, nonpyrogenic, in-line filter (pore size of 0.2 to 1.2 micrometers).

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F). Reconstituted solution should be further diluted and used immediately but may be stored below 25° C for a maximum of 1 hour before further dilution. Diluted solution must be used within 6 hours if kept at RT or may be immediately refrigerated. Complete the infusion within 24 hours. Do not freeze.

COMPATIBILITY

Manufacturer states, “Do not infuse isavuconazonium with other intravenous medications.” **Compatible** only with NS or D5W.

RATE OF ADMINISTRATION

Do not administer as an IV bolus; for use as a diluted IV infusion only. Administer a single dose as an infusion equally distributed over a minimum of 60 minutes. Flush the IV line before and after each isavuconazonium infusion with NS or D5W. Administer through an infusion set that contains a sterile, nonpyrogenic, in-line filter (pore size of 0.2 to 1.2 micrometers).

ACTIONS

Isavuconazonium is a prodrug of isavuconazole, an azole antifungal drug. Acts by inhibiting the synthesis of ergosterol, a key component of fungal cell membranes. Rapidly hydrolyzed in blood to isavuconazole by esterases, predominantly by butylcholinesterase. Extensively distributed and highly protein bound, predominantly to albumin. Following IV administration, maximum plasma concentrations of the prodrug and inactive products were detectable during infusion and declined rapidly following the end of administration. Mean plasma half-life is 130 hours. CYP3A4, CYP3A5 and, subsequently, uridine diphosphate-glucuronosyltransferase (UGT) are involved in the metabolism of isavuconazole. Primarily excreted as metabolites in urine and feces.

INDICATIONS AND USES

Treatment of invasive aspergillosis and invasive mucormycosis in patients 18 years of age and older.

CONTRAINDICATIONS

Known hypersensitivity to isavuconazole. ■ Coadministration of strong CYP3A4 inhibitors such as ketoconazole or high-dose ritonavir (Norvir [400 mg every 12 hours]). ■ Coadministration of strong CYP3A4 inducers such as rifampin, carbamazepine, St. John’s wort, or long-acting barbiturates (e.g., phenobarbital). ■ Patients with familial short QT syndrome. ■ See Drug/Lab Interactions.

PRECAUTIONS

Do not administer as an IV bolus; for use as a diluted IV infusion only. ■ Elevations in liver function tests (e.g., ALT, AST, alkaline phosphatase, total bilirubin) have been reported, were generally reversible, and did not require discontinuation of isavuconazonium. ■ Severe hepatic reactions (e.g., cholestasis, hepatitis, or hepatic failure, including death) have been reported in patients with serious underlying medical conditions (e.g., hematologic malignancy) during treatment with azole antifungal agents, including isavuconazonium. ■ Has not been studied in patients with severe hepatic impairment (Child-Pugh Class C); use in these patients only when benefits outweigh risks. ■ Infusion-related reactions have been reported. ■ Serious hypersensitivity and severe skin reactions, such as anaphylaxis or Stevens-Johnson syndrome, have been reported with other azole antifungal agents. There is no information regarding cross-sensitivity between isavuconazole and other azole antifungal agents. Use caution in patients with hypersensitivity to other azoles. ■ In vitro and animal studies suggest cross-resistance between isavuconazole and other azoles. Relevance of cross-resistance to clinical outcome has not been fully characterized. Patients failing prior azole therapy may require alternative antifungal therapy. ■ See Drug/Lab Interactions.

Monitor:

Obtain specimens for fungal culture and other relevant lab studies (including histopathology) to isolate and identify causative organism(s) before initiating therapy. Institute antifungal therapy and adjust based on results of culture and lab studies. ■ Obtain baseline liver function tests and repeat as necessary. Monitor more frequently in patients who develop abnormal liver function tests and when treating patients with severe hepatic impairment. ■ Monitor for infusion-related reactions (e.g., chills, dizziness, dyspnea, hypoesthesia, hypotension, and paresthesia). ■ Monitor for S/S of hypersensitivity reactions (e.g., hypotension, rash, tightness of the chest, urticaria, wheezing). ■ Monitor for S/S of skin reactions (e.g., rash, blisters).

Patient Education:

Review manufacturer’s medication guide. ■ Review of health history and medication profile is imperative. ■ Avoid pregnancy; effective birth control recommended; see Drug/Lab Interactions. Should pregnancy occur, notify physician and discuss potential hazards. ■ Promptly report S/S of a hypersensitivity/infusion reaction (e.g., itching, hives, shortness of breath, or a serious skin reaction [e.g., rash]).

Maternal/Child:

Category C: may cause fetal harm. Use during pregnancy only if the potential benefit to the patient outweighs the risk to the fetus. Report a suspected pregnancy. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in patients under 18 years of age have not been established.

Elderly:

Response similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

Isavuconazole is a sensitive substrate of CYP3A4. CYP3A4 inhibitors or inducers may alter the plasma concentrations of isavuconazole. Isavuconazole is a moderate inhibitor of CYP3A4, a mild inhibitor of P-glycoprotein (P-gp), and an organic cation transporter 2 (OCT2). ■ Coadministration of isavuconazonium with **strong CYP3A4 inhibitors** such as ketoconazole or high-dose ritonavir is ***contraindicated***. Strong CYP3A4 inhibitors can significantly increase the plasma concentration of isavuconazole. ■ Coadministration of isavuconazonium with **strong CYP3A4 inducers** such as rifampin, carbamazepine, St. John's wort, or long-acting barbiturates is ***contraindicated.*** Strong CYP3A4 inducers can significantly decrease the plasma concentration of isavuconazole. ■ Coadministration with **lopinavir/ritonavir** can significantly increase the plasma concentration of isavuconazole, and **isavuconazole** may decrease the antiviral effectiveness of lopinavir/ritonavir. ■ Coadministration with **atorvastatin** may increase atorvastatin exposure and toxicity. ■ Coadministration with **cyclosporine, mycophenolate, sirolimus,** and **tacrolimus** may increase exposure of these drugs. Monitor drug concentrations of these drugs and/or drug-related toxicities and adjust doses as needed. ■ May increase exposure of **midazolam**. Consider dose reduction of midazolam with concomitant administration. ■ May decrease exposure of **bupropion**. Dose increase of bupropion may be necessary with coadministration; do not exceed the maximum recommended dose. ■ Concomitant administration with **digoxin** increases digoxin exposure. Monitor serum digoxin concentrations and adjust dose as necessary.

SIDE EFFECTS

The most commonly reported side effects include back pain; constipation; cough; diarrhea; dyspnea; elevated ALT, AST, alkaline phosphatase, total bilirubin, and GGT; headache; hypokalemia; nausea and vomiting; and peripheral edema. Hepatic adverse drug reactions, infusion-related or hypersensitivity reactions, and embryo-fetal toxicity are considered the most serious. Abdominal pain, acute respiratory failure, anxiety, chest pain, decreased appetite, delirium, dyspepsia, fatigue, hypomagnesemia, hypotension, injection site reaction, insomnia, pruritus, rash, and renal failure have also been reported.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. If a hypersensitivity reaction, infusion reaction, or severe cutaneous reaction occurs, discontinue the infusion and treat as indicated. Discontinue isavuconazonium if clinical S/S consistent with liver disease develop that may be attributable to isavuconazonium. No known specific antidote. Not removed by hemodialysis.

ISOPROTERENOL HYDROCHLORIDE

(**eye**-so-**PROH**-ter-ih-nohl hy-droh-**KLOR**-eyed)
Isuprel
Cardiac stimulant (inotropic/chronotropic)
Bronchodilator
Antiarrhythmic
pH 3.5 to 4.5

USUAL DOSE

In all situations, adjust the rate of infusion based on HR, CVP, BP, respiratory rate, and urine output.

Recommended Isoproterenol Dose for Adults With Atropine-Resistant Hemodynamically Significant Bradycardia, Heart Block, Adams-Stokes Attacks, and Cardiac Arrest

Route of Administration	Preparation of Dilution	Initial Dose	Subsequent Dose Range[a]
Bolus intravenous injection	Dilute 1 mL (0.2 mg) to 10 mL with NS or D5W	0.02 to 0.06 mg (1 to 3 mL of diluted solution)	0.01 to 0.2 mg (0.5 to 10 mL of diluted solution)
Intravenous infusion	Dilute 10 mL (2 mg) in 500 mL D5W (4 mcg/mL)	5 mcg/min (1.25 mL of diluted solution per minute)	
Intracardiac	Use solution 0.2 mg/mL undiluted	0.02 mg (0.1 mL)	

[a] Subsequent dose depends on the ventricular rate and the rapidity with which the cardiac pacemaker can take over when the drug is gradually withdrawn.

AHA recommendation is 2 to 10 mcg/min if an external pacemaker is not available.

Recommended Isoproterenol Dose for Adults With Shock (Cardiogenic, CHF, Hypoperfusion [Low Cardiac Output], Hypovolemic, Septic)

Route of Administration	Preparation of Dilution[a]	Infusion Rate[b]
Intravenous infusion	Dilute 5 mL (1 mg) in 500 mL of D5W (2 mcg/mL)	0.5 to 5 mcg/min (0.25 to 2.5 mL of diluted solution)

[a] Concentrations up to 10 times greater have been used when limitation of volume is essential.

[b] Rates over 30 mcg/min have been used in advanced stages of shock. Adjust infusion rate based on HR, CVP, BP, and urine flow. If HR exceeds 110 beats/min, consider decreasing rate or temporarily discontinue the infusion.

Recommended Isoproterenol Dose for Adults With Bronchospasm Occurring During Anesthesia

Route of Administration	Preparation of Dilution	Initial Dose	Subsequent Dose
Bolus intravenous injection	Dilute 1 mL (0.2 mg) to 10 mL with NS or D5W	0.01 to 0.02 mg (0.5 to 1 mL of diluted solution)	Repeat initial dose as necessary

Complete heart block following closure of ventricular septal defects:

0.04 to 0.06 mg (2 to 3 mL of a 0.02 mg/mL dilution) as a bolus injection. May maintain a sinus rhythm with a HR above 90 to 100 beats/min or may relapse into complete heart block again.

Diagnosis of mitral regurgitation (unlabeled):

4 mcg/min as an infusion (1 mL/min of a 4 mcg/mL dilution).

Diagnosis of coronary artery disease or lesions (unlabeled):

1 to 3 mcg/min as an infusion (0.25 to 0.75 mL/min of a 4 mcg/mL dilution).

Refractory torsades de pointes, bradycardia in heart transplant patients, beta-adrenergic blocker poisoning:

AHA recommends 2 to 10 mcg/min (0.5 to 2.5 mL/min of a 4 mcg/mL dilution). Titrate to adequate heart rate. In torsades de pointes, titrate to increase heart rate until VT is suppressed.

PEDIATRIC DOSE

See Dilution and Maternal/Child.

0.05 to 2 mcg/kg/min. Begin with 0.1 mcg/kg/min as an infusion. Increase by 0.1 mcg/kg/min until desired effect. Titrate to patient response and monitor cardiac status carefully. Maximum dose is 2 mcg/kg/min. Another source suggests a maximum dose of 1 mcg/kg/min.

Complete heart block after closure of ventricular septal defects in infants:

0.01 to 0.03 mg (0.5 to 1.5 mL of a 0.02 mg/mL solution) as a bolus injection. See comments in Usual Dose.

DOSE ADJUSTMENTS

Lower-end initial doses may be appropriate in the elderly; consider the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

IV injection:

Available in a 0.2 mg/mL solution. Dilute 1 mL of a 0.2 mg/mL solution with 10 mL NS or D5W to provide a concentration of 0.02 mg/mL.

Infusion:

Atropine-resistant, hemodynamically significant bradycardia, heart block, Adams-Stokes attacks, and cardiac arrest: Dilute 10 mL (2 mg of a 0.2 mg/mL solution) in 500 mL D5W (4 mcg/mL). ***Shock:*** Dilute 5 mL (1 mg of a 0.2 mg/mL solution) in 500 mL D5W (2 mcg/mL). Use an infusion pump or microdrip (60 gtts equals 1 mL) to administer. Less diluent may be used to reduce fluid intake.

Filters:

No data available from manufacturer. Another source cites no significant loss in drug potency in several studies using various types and sizes of filters from 0.22 to 5 microns in size.

Storage:

Store between 8° and 15° C (46° to 59° F) unless otherwise specified by manufacturer. Do not use if pink or brown in color or contains a precipitate.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

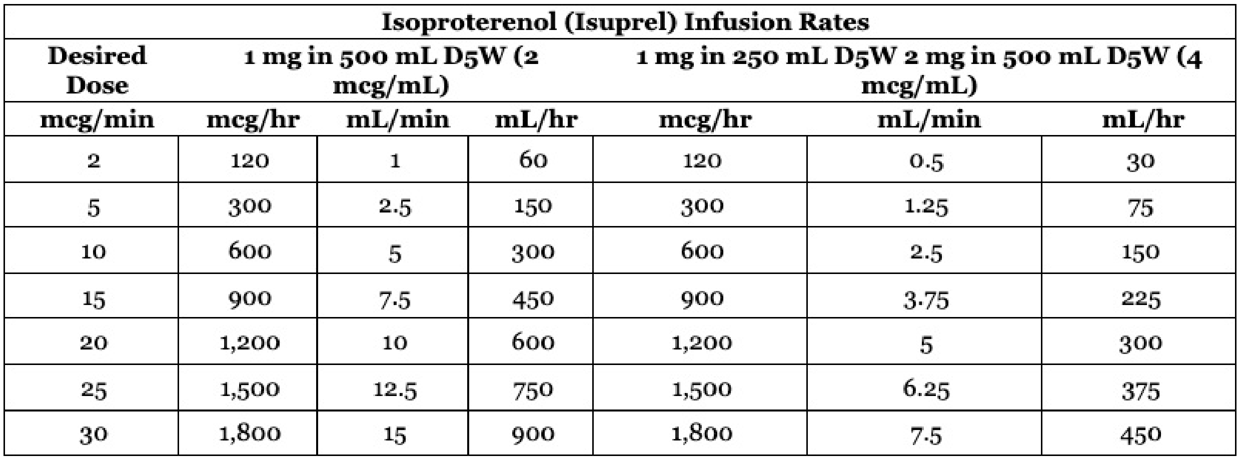
RATE OF ADMINISTRATION

IV injection:

Each 1 mL of a 0.02 mg/mL solution or fraction thereof over 1 minute. Follow with a 20-mL flush of NS if indicated to ensure distribution to circulation.

Infusion:

Titrate to desired dose, HR, and rhythm; see the following infusion rate chart. Decrease rate of infusion as necessary. Ventricular rate generally should not exceed 110 beats/min.



Isoproterenol (Isuprel) Infusion Rates

Desired Dose	1 mg in 500 mL D5W (2 mcg/mL)			1 mg in 250 mL D5W 2 mg in 500 mL D5W (4 mcg/mL)		
mcg/min	mcg/hr	mL/min	mL/hr	mcg/hr	mL/min	mL/hr
2	120	1	60	120	0.5	30
5	300	2.5	150	300	1.25	75
10	600	5	300	600	2.5	150
15	900	7.5	450	900	3.75	225
20	1,200	10	600	1,200	5	300
25	1,500	12.5	750	1,500	6.25	375
30	1,800	15	900	1,800	7.5	450

ACTIONS

A nonselective synthetic cardiac beta receptor stimulant (sympathomimetic amine) similar to epinephrine and norepinephrine. Has positive inotropic and chronotropic actions more potent than those of epinephrine. It increases cardiac output, cardiac work, coronary flow, and venous return. Improves atrioventricular conduction. Stimulates only the higher ventricular foci, allowing a more normal cardiac pacemaker to take over, thus suppressing ectopic pacemaker activity. Decreases peripheral vascular resistance by relaxing arterial smooth muscle and is a most effective bronchial smooth muscle relaxant. Onset of action is immediate and lasts 1 to 2 hours. Metabolized by the liver and inactivated by various enzyme systems. Excreted in the urine.

INDICATIONS AND USES

Treatment of mild or transient episodes of heart block that do not require cardioversion or pacemaker therapy. ■ Treatment of serious episodes of heart block and Adams-Stokes attacks (except when caused by VT or VF). ■ May be used in cardiac arrest until defibrillation or pacemaker (the treatments of choice) is available. ■ Bronchospasm during anesthesia. ■ Management of shock (cardiogenic, CHF, hypoperfusion [low cardiac output], hypovolemic, septic). Adequate fluid and electrolyte replacement required. ■ AHA recommends cautious use in symptomatic bradycardia if a pacemaker is not available, treatment of refractory torsades de pointes unresponsive to magnesium sulfate, temporary control of bradycardia in heart transplant patients (denervated heart unresponsive to atropine), and treatment of poisoning from beta-adrenergic blockers (e.g., metoprolol).

Unlabeled uses:

Aid in diagnosis of the etiology of mitral regurgitation. ■ Aid in diagnosis of coronary artery disease or lesions. ■ Pulmonary embolism to increase pulmonary blood volume and decrease pulmonary arterial pressure and vascular resistance.

CONTRAINDICATIONS

Tachyarrhythmias, patients with tachycardia or heart block caused by digoxin intoxication, angina pectoris, ventricular arrhythmias that require inotropic therapy.

PRECAUTIONS

IV injection in cardiac standstill must be accompanied by cardiac massage to perfuse drug into the myocardium. Current JAMA recommendations do not include isoproterenol in the treatment of cardiac arrest or hypotension. ■ Fourth-line agent for bradycardia; considered possibly helpful but may be harmful. ■ Can cause a severe drop in BP and can be very harmful in bradycardia. ■ Use extreme caution when inhalant anesthetics (e.g., cyclopropane) are being administered and supplementary to digoxin administration. ■ Use caution in coronary insufficiency, diabetes, hyperthyroidism, known sensitivity to sympathomimetic amines, history of seizures, hypertension, and pre-existing cardiac arrhythmias with tachycardia. ■ Increased cardiac output and work can increase ischemia and worsen arrhythmias. ■ Contains sulfites; use caution in allergic patients.

Monitor:

Decrease rate of infusion as necessary. Ventricular rate generally should not exceed 110 beats/min. Maintain adequate blood volume and correct acidosis. ■ Continuous cardiac monitoring, central venous pressure readings, BP, respiratory rate, and urine flow measurements are advisable during therapy with isoproterenol. ■ Monitoring of serum glucose, magnesium, and potassium may be indicated. ■ See Drug/Lab Interactions and Maternal/Child.

Maternal/Child:

Category C: safety for use in pregnancy or breast-feeding not established. Benefits must outweigh risks. ■ Safety and effectiveness in pediatric patients not established. ■ In asthmatic pediatric patients, IV infusion of isoproterenol has caused clinical deterioration, myocardial necrosis, CHF, and death. Risks of cardiac toxicity may be increased by other factors such as acidosis, hypoxemia, coadministration of corticosteroids or methylxanthines (e.g., aminophylline). Continuous assessment of VS, frequent ECGs, and daily measurement of cardiac enzymes (e.g., CPK, MB) is suggested if isoproterenol infusion is required.

Elderly:

Difference in response from younger adults not known. May be more sensitive to the effects of beta-adrenergic agents (e.g., hypertension, hypokalemia, tachycardia, tremor). Patients with cardiac disease may be at increased risk for cardiac effects. ■ Lower-end initial doses may be appropriate; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May be used alternately with epinephrine, but they may not be used together. Both are direct cardiac stimulants; serious arrhythmias and death may result. An adequate interval between doses must be maintained. ■ Do not use concomitantly with other **sympathomimetic agents** (e.g., ephedrine, dopamine). Additive effects may cause toxicity. May be used after effects of previous drug have subsided. ■ Simultaneous use with **oxytoxics** may cause hypertensive crisis. ■ May cause hypertension with **guanethidine** (Ismelin). ■ **Digoxin, quinidine, and halogenated hydrocarbon anesthetics** (e.g., halothane) may sensitize myocardium and cause serious arrhythmias. ■ Antagonized by **propranolol.** May be used to treat tachycardia caused by isoproterenol, but tachycardia and hypotension secondary to peripheral vasodilation may occur. ■ Potentiated by **tricyclic antidepressants**. ■ Concomitant use with **theophylline** increases the risk of cardiotoxicity. ■ See Contraindications.

SIDE EFFECTS

Anginal pain, cardiac arrhythmias, flushing, headache, hyperglycemia, hypokalemia, nausea, nervousness, palpitations, sweating, tachycardia, vomiting. Cardiac dilation, marked hypotension, pulmonary edema, and death may occur with prolonged use or overdose. Adams-Stokes attacks have been reported.

ANTIDOTE

Notify the physician of any side effect. Treatment will probably be symptomatic. For ventricular rate over 110 beats/min, PVCs, or ECG changes, decrease rate of infusion or discontinue drug. Vasodilators (e.g., nitrates) may be useful for treatment of hypertension. For accidental overdose, discontinue drug immediately, resuscitate and sustain patient, and notify physician.

IXABEPILONE BBW

(ix-ab-**EP**-i-lone)

Ixempra Kit
Antineoplastic (microtubule inhibitor)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

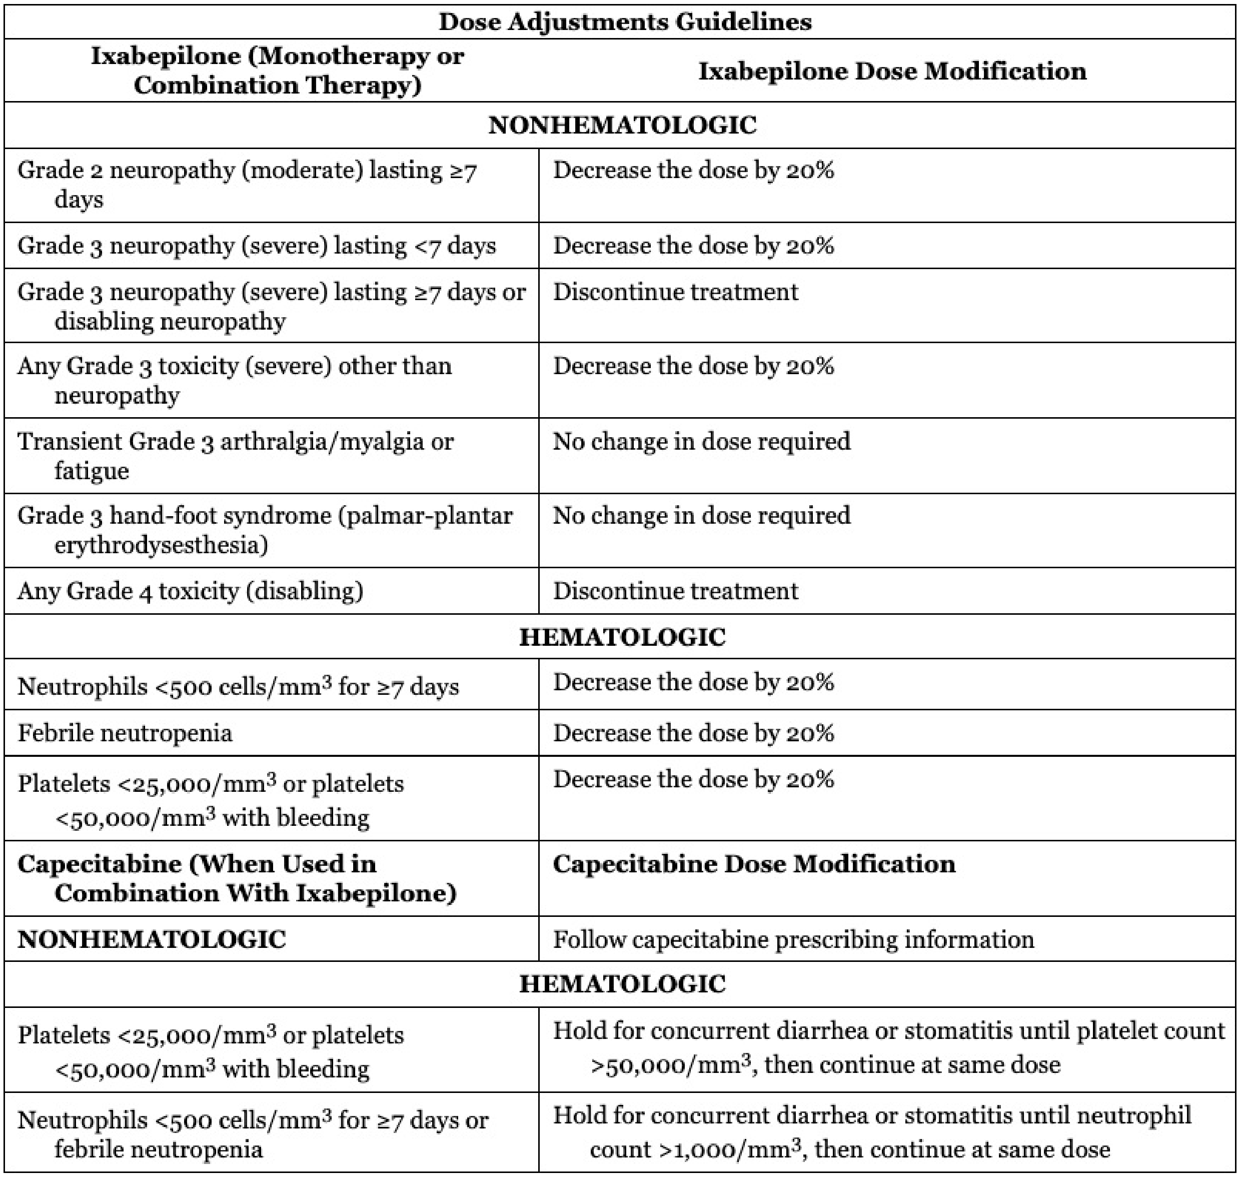
An H_1 antagonist (e.g., diphenhydramine) and an H_2 antagonist (e.g., famotidine) should be administered orally 60 minutes prior to ixabepilone to minimize the chance of a hypersensitivity reaction. Patients who experience a hypersensitivity reaction require premedication with a corticosteroid (e.g., dexamethasone 20 mg IV 30 minutes before infusion or orally 60 minutes before infusion) in addition to pretreatment with the H_1 and H_2 antagonists.

Ixabepilone:

40 mg/M^2 as an infusion over 3 hours every 3 weeks. Doses for patients with a body surface area (BSA) greater than 2.2 M^2 should be calculated based on 2.2 M^2. Administered alone or in combination with capecitabine (Xeloda) 1,000 mg/M^2 twice daily for 2 weeks followed by 1 week of rest.

DOSE ADJUSTMENTS

If toxicities are present, therapy should be delayed to allow recovery. ■ Dosing adjustment guidelines for monotherapy and combination therapy are listed in the following chart. *If toxicities recur, an additional 20% dose reduction should be made.*



Dose Adjustments Guidelines	
Ixabepilone (Monotherapy or Combination Therapy)	**Ixabepilone Dose Modification**
NONHEMATOLOGIC	
Grade 2 neuropathy (moderate) lasting ≥7 days	Decrease the dose by 20%
Grade 3 neuropathy (severe) lasting <7 days	Decrease the dose by 20%
Grade 3 neuropathy (severe) lasting ≥7 days or disabling neuropathy	Discontinue treatment
Any Grade 3 toxicity (severe) other than neuropathy	Decrease the dose by 20%
Transient Grade 3 arthralgia/myalgia or fatigue	No change in dose required
Grade 3 hand-foot syndrome (palmar-plantar erythrodysesthesia)	No change in dose required
Any Grade 4 toxicity (disabling)	Discontinue treatment
HEMATOLOGIC	
Neutrophils <500 cells/mm^3 for ≥7 days	Decrease the dose by 20%
Febrile neutropenia	Decrease the dose by 20%
Platelets <25,000/mm^3 or platelets <50,000/mm^3 with bleeding	Decrease the dose by 20%
Capecitabine (When Used in Combination With Ixabepilone)	**Capecitabine Dose Modification**
NONHEMATOLOGIC	Follow capecitabine prescribing information
HEMATOLOGIC	
Platelets <25,000/mm^3 or platelets <50,000/mm^3 with bleeding	Hold for concurrent diarrhea or stomatitis until platelet count >50,000/mm^3, then continue at same dose
Neutrophils <500 cells/mm^3 for ≥7 days or febrile neutropenia	Hold for concurrent diarrhea or stomatitis until neutrophil count >1,000/mm^3, then continue at same dose

Dose adjustments at the start of a cycle should be based on nonhematologic toxicity or blood counts from the preceding cycle following the previous guidelines. Patients should not begin a new cycle unless the neutrophil count is at least 1,500 cells/mm^3, the platelet count is at least 100,000 cells/mm^3, and nonhematologic toxicities have improved to Grade 1 (mild) or have resolved. ■ Combined use with capecitabine is contraindicated in patients who have AST or ALT greater than 2.5 times the ULN or bilirubin greater than 1 times the ULN; see Contraindications and Precautions. ■ Patients with hepatic impairment who are receiving monotherapy should be dosed according to the guidelines listed in the following chart.

Dose Adjustments for Ixabepilone as Monotherapy in Patients With Hepatic Impairment

	Transaminase Levels		Bilirubin Levels[a]	Ixabepilone Dose[b] (mg/M^2)
Mild	AST and ALT ≤2.5 × ULN	and	≤1 × ULN	40
	AST or ALT ≤10 × ULN	and	≤1.5 × ULN	32
Moderate	AST and ALT ≤10 × ULN	and	>1.5 × ULN to ≤3 × ULN	20-30
Severe	AST or ALT >10 × ULN	or	>3 × ULN	Not recommended

[a] Excluding patients whose total bilirubin is elevated due to Gilbert's disease.

[b] Dosage recommendations are for the first course of therapy; further decreases in subsequent courses should be based on individual tolerance.

Patients with moderate hepatic impairment should start with 20 mg/M^2. The dose in subsequent cycles may be increased up to, but should not exceed, 30 mg/M^2 if tolerated. ■ Reduce dose to 20 mg/M^2 when coadministered with a strong CYP3A4 inhibitor; see Drug/Lab Interactions. If the strong inhibitor is discontinued, wait for at least 1 week before adjusting the ixabepilone dose upward to the indicated dose. ■ If coadministration of a strong CYP3A4 inducer is required and alternatives are not feasible (e.g., the patient has been maintained on a strong CYP3A4 inducer), the dose may be gradually increased from 40 mg/M^2 to 60 mg/M^2 if tolerated; see Drug/Lab Interactions. Increase infusion duration of 60 mg/M^2 dose to 4 hours and monitor patient closely for toxicity. If CYP3A4 inducer is discontinued, return to original dose. ■ No dose adjustment indicated based on age, race, and gender. ■ Minimally excreted by the kidney; no studies conducted in patients with renal impairment.

DILUTION

Specific techniques required; see **Precautions**.

Available as a 15-mg or 45-mg Ixempra Kit that contains two vials; one vial contains the indicated amount of ixabepilone, and the other contains a manufacturer-supplied diluent. Only the manufacturer-supplied diluent may be used for reconstitution. Calculate dose and remove required number of kits from refrigerator. Let stand at RT for approximately 30 minutes. A white precipitate may appear in the diluent vial. This will dissolve as the vial warms to RT. Withdraw diluent and slowly inject it into the ixabepilone vial. (The 15-mg vial is reconstituted with 8 mL of diluent, and the 45-mg vial is reconstituted with 23.5 mL.) Gently swirl and invert until completely dissolved. Concentration of reconstituted solution is 2 mg/mL. Must be further diluted to a final concentration of 0.2 to 0.6 mg/mL with LR, Plasma-Lyte A Injection pH 7.4, or NS 250 to 500 mL (the pH of the NS must be adjusted to between 6 and 9 by adding 2 mEq [i.e., 2 mL of an 8.4% w/v solution or 4 mL of a 4.2% w/v solution] of sodium bicarbonate injection before adding the ixabepilone). A 250-mL bag will be sufficient for most doses. Withdraw the calculated dose from the ixabepilone vials and transfer to a DEHP-free IV bag containing an appropriate volume of infusion solution to achieve the final desired concentration. Thoroughly mix by manual rotation. Should be administered through a DEHP-free, polyethylene-lined administration set.

Filter:

Must be administered through an in-line filter with a microporous membrane of 0.2 to 1.2 microns.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F) in original carton. Protect from light. Reconstituted solution may be stored in vial for 1 hour at RT and room light. Once diluted, solution is stable for a maximum of 6 hours at RT. Administration must be completed within this 6-hour period.

COMPATIBILITY

Manufacturer states, “DEHP-free infusion containers and administration sets must be used.” Must be reconstituted with manufacturer-supplied diluent only and further diluted with the infusion solutions noted in Dilution. Indicated solutions have a pH between 6 to 9, which is required for ixabepilone stability.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 3 hours. In patients who experience a hypersensitivity reaction, increase duration of infusion and premedicate with corticosteroids and H_1 and H_2 antagonists; see Usual Dose. Increase duration of infusion to 4 hours in patients receiving 60 mg/M^2 dose; see Dose Adjustments.

ACTIONS

A microtubule inhibitor belonging to a class of antineoplastic agents, the epothilones. A semi-synthetic analog of epothilone B. Binds directly to β-tubulin subunits on microtubules, leading to suppression of microtubule dynamics. Blocks cells in the mitotic phase of the cell division cycle, leading to cell death. Has antitumor activity against multiple human tumor xenografts and is active in xenografts that are resistant to multiple agents, including taxanes, anthracyclines, and vinca alkaloids. Has demonstrated synergistic antitumor activity in combination with capecitabine. In addition to direct antitumor activity, ixabepilone has antiangiogenic activity. 67% to 77% bound to plasma proteins. Extensively metabolized in the liver, primarily by CYP3A4. Eliminated primarily as metabolized drug in feces and urine. Half-life is approximately 52 hours.

INDICATIONS AND USES

In combination with capecitabine for the treatment of patients with metastatic or locally advanced breast cancer resistant to treatment with an anthracycline and a taxane or for patients whose cancer is taxane resistant and for whom further anthracycline therapy is contraindicated. Anthracycline resistance is defined as progression while on therapy or within 6 months in the adjuvant setting or 3 months in the metastatic setting. Taxane resistance is defined as progression while on therapy or within 12 months in the adjuvant setting or 4 months in the metastatic setting. ■ As monotherapy for the treatment of metastatic or locally advanced breast cancer in patients whose tumors are resistant or refractory to anthracyclines, taxanes, and capecitabine.

CONTRAINDICATIONS

History of severe (CTCAE Grade 3 or 4) hypersensitivity reaction to agents containing Cremophor EL or its derivatives. ■ Neutrophil count less than 1,500 cells/mm^3 or platelet count less than 100,000 cells/mm^3. ■ In combination with capecitabine in patients with AST or ALT greater than 2.5 times the ULN or bilirubin greater than 1 times the ULN.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Should be administered by or under the direction of the physician specialist in facilities equipped to monitor the patient and respond to any medical emergency. ■ Ixabepilone in combination with capecitabine is contraindicated in patients with significant hepatic insufficiency due to increased risk of toxicity and neutropenia-related death; see Contraindications. ■ Use caution in patients with hepatic insufficiency receiving monotherapy. Risk of toxicity is increased and data are limited; see Dose Adjustments. ■ Premedication is required to minimize the chance of a hypersensitivity reaction; see Usual Dose. ■ Peripheral neuropathy is a common side effect and was the most common cause of treatment discontinuation in clinical studies. It is cumulative and generally reversible. May require dose reduction or delay in therapy; see Dose Adjustments. Use caution in patients with diabetes mellitus or pre-existing peripheral neuropathy. Risk of severe neuropathy may be increased. ■ Myelosuppression is dose dependent and primarily manifested as neutropenia. Hold therapy in patients with a neutrophil count less than 1,500 cells/mm^3; see Dose Adjustments and Contraindications. ■ Use caution in patients with a history of cardiac disease. Adverse cardiac events (e.g., myocardial ischemia, ventricular dysfunction, and supraventricular arrhythmias) have been reported. ■ Not studied in patients with renal impairment.

Monitor:

Obtain baseline and periodic CBC with differential and platelet count. ■ Obtain baseline and periodic bilirubin, AST, and ALT. ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, flushing, rash). ■ Monitor for S/S of peripheral neuropathy (primarily sensory [e.g., burning sensation, discomfort, hyperesthesia, hypoesthesia, neuropathic pain or paresthesia]). Most cases of new-onset or worsening neuropathy occurred during the first 3 cycles. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3); see Dose Adjustments and Contraindications. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Promptly report any numbness or tingling of feet, S/S of infection (fever, chills cough), or S/S of a hypersensitivity reaction (chest tightness, dyspnea, flushing, pruritus, rash, urticaria). ■ Avoid pregnancy. Use of effective birth control is required. ■ Promptly report chest pain, difficulty breathing, palpitations, or unusual weight gain; these may be signs of adverse cardiac events.

Maternal/Child:

Category D: avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding. ■ Effectiveness for use in pediatric patients not established. Evaluation in two clinical studies suggests that pediatric patients have a safety profile consistent with that seen in adults.

Elderly:

The incidence of Grade 3 and 4 adverse reactions was higher when used in combination with capecitabine in clinical studies. As monotherapy, no overall difference in safety was seen in the elderly compared with younger adults.

DRUG/LAB INTERACTIONS

Use of concomitant strong **CYP3A4 inhibitors** (e.g., amprenavir, atazanavir, clarithromycin, delavirdine, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, or voriconazole [VFEND]) may increase plasma concentrations of ixabepilone. Avoid concomitant use if possible. If required, decrease dose of ixabepilone to 20 mg/M^2 and monitor closely for acute toxicity. If strong inhibitor is discontinued, wait for at least 1 week before adjusting ixabepilone dose upward to indicated dose. ■ **Grapefruit juice** may increase plasma concentrations of ixabepilone and should be avoided. ■ **Rifampin**, a potent CYP3A4 inducer, decreases ixabepilone plasma concentrations. Other strong **CYP3A4 inducers** (e.g., carbamazepine, dexamethasone, phenobarbital, phenytoin, rifabutin) may also decrease ixabepilone plasma concentrations, decreasing effectiveness. Avoid use if possible; see Dose Adjustments. ■ **St. John's wort** may decrease ixabepilone plasma concentrations, decreasing effectiveness. Avoid use. ■ Ixabepilone does not inhibit CYP enzymes and is not expected to alter plasma concentrations of other drugs.

SIDE EFFECTS

The most common side effects in patients receiving monotherapy included alopecia, anemia, arthralgia, asthenia, diarrhea, fatigue, leukopenia, mucositis, musculoskeletal pain, myalgia, nausea, neutropenia, peripheral sensory neuropathy, stomatitis, thrombocytopenia, and vomiting. In combination therapy, the following additional side effects were commonly reported: abdominal pain, anorexia, constipation, nail disorder, and hand-foot syndrome (palmar-plantar erythrodysesthesia). Other less commonly reported side effects included chest pain, cough, dehydration, dizziness, dyspnea, edema, febrile neutropenia, fever, gastroesophageal reflux disease, headache, hot flush, hypersensitivity reactions (including anaphylaxis), increased lacrimation, infection, insomnia, pain, pruritus, rash, skin exfoliation, skin hyperpigmentation, taste disorder.

Overdose:

Fatigue, GI symptoms (e.g., abdominal pain, anorexia, diarrhea, nausea, stomatitis), musculoskeletal pain/myalgia, and peripheral neuropathy.

Post-Marketing:

Radiation recall has been reported.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Monitor patient closely. Discontinuation should be considered in patients who develop cardiac ischemia or impaired cardiac function. Discontinue ixabepilone at the first sign of a severe hypersensitivity reaction. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Patients who experience a hypersensitivity reaction may be able to continue therapy. Rate reduction and additional pretreatment with corticosteroids may be attempted in subsequent cycles; see Usual Dose.

---

[a] Please see p. xi for more information on biosimilars.

Generic drugs: K

KANAMYCIN SULFATE
KETOROLAC TROMETHAMINE

K

KETOROLAC TROMETHAMINE BBW

(kee-toh-**ROH**-lack tro-**METH**-ah-meen)
Toradol
NSAID
pH 6.9 to 7.9

USUAL DOSE

Pretreatment:

See Monitor.

Adults under 65 years:

30 mg. May repeat every 6 hours. Maximum dose is 120 mg/24 hr. Do not increase the dose or frequency for breakthrough pain. Consider alternating with low doses of opioids (e.g., morphine or meperidine). Ketorolac oral may be used only as continuation therapy to parenteral dosing. Maximum oral dose is 40 mg/24 hr. Do not administer for longer than 5 days (IV/IM alone or combined use with oral).

Adults over 65 years, patients with impaired renal function, and/or patients under 50 kg (110 lb):

15 mg. May repeat every 6 hours. Maximum dose is 60 mg in 24 hours. Note all restrictions for adults under 65 years outlined above.

PEDIATRIC DOSE

See Maternal/Child.

Pediatric patients 2 to 16 years of age:

One dose of 0.5 mg/kg up to a maximum dose of 15 mg. 0.5 mg/kg IV every 6 hours has been administered in a limited number of patients (unlabeled).

Short-term postoperative pain management (unlabeled):

1 mg/kg alone or as an adjunct.

DOSE ADJUSTMENTS

Required for patients under 50 kg (110 lb), patients over 65 years of age, and patients with reduced renal function (moderately elevated SCr); see Usual Dose. Further dose reductions may be required with high-dose salicylates; see Drug/Lab Interactions.

DILUTION

Confirm IV use. Some 2-mL tubex syringes are for IM use only. May be given undiluted through Y-tube or three-way stopcock of infusion set. Administration through a free-flowing IV is preferred.

Storage:

Store at CRT; protect from light.

COMPATIBILITY

May form a precipitate if admixed with drugs with a low pH (e.g., meperidine, morphine, promethazine).

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over a minimum of 15 seconds; evenly distributed over 1 to 2 minutes is preferred.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID) with peripheral analgesic, antiinflammatory, and antipyretic actions. Inhibits prostaglandin synthesis. 30 to 60 mg produces analgesia similar to morphine 12 mg or Demerol 100 mg. Studies reflect less drowsiness, nausea, and vomiting. Not a narcotic agonist or antagonist. Cardiac and hemodynamic parameters are not altered. Onset of action is 30 to 60 minutes. Half-life varies from 3.8 to 8.6 hours based on age and clinical status. Relief in some patients may last 6 to 8 hours. Excreted primarily in urine. Secreted in breast milk.

INDICATIONS AND USES

Short-term management of moderately severe, acute pain (no longer than 5 days). ■ NOT indicated for minor or chronic painful conditions.

Unlabeled uses:

Postoperative short-term pain management in pediatric patients.

CONTRAINDICATIONS

Hypersensitivity to ketorolac, its components, or to acetylsalicylic acid (ASA) or other NSAIDs; labor and delivery; breast-feeding; preoperative or intraoperative medication when hemostasis is critical due to increased risk of bleeding; patients currently receiving ASA or NSAIDs (e.g., ibuprofen [Advil, Motrin], naproxen [Aleve, Naprosyn]); active peptic ulcer disease; recent GI bleeding or perforation; patients with a history of peptic ulcer disease or GI bleeding; suspected or confirmed cerebrovascular bleeding; hemorrhagic diathesis; incomplete hemostasis; high risk of bleeding; advanced renal impairment; or patients at risk for renal failure because of volume depletion. Do not use for epidural or intrathecal administration; contains alcohol. See Drug/Lab Interactions.

PRECAUTIONS

Use only recommended doses; increased doses will not be more effective and will increase the risk of serious adverse events. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Nonsteroidal anti-inflammatory drugs (NSAIDs) may increase the risk of serious cardiovascular (CV) thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. Patients with cardiovascular disease or risk factors for cardiovascular disease may be at greater risk. ■ Inhibits platelet aggregation and may prolong bleeding time. ■ May cause serious GI ulceration and bleeding without warning. ■ In addition to the usual caution in patients with reduced hepatic or renal function, ketorolac may also cause a dose-dependent reduction in renal prostaglandin formation. Can precipitate renal failure in patients with impaired renal function, heart failure, or liver dysfunction; in the elderly; or in patients receiving diuretics. ■ Use caution in patients with cardiac decompensation, hypertension, or similar conditions; may cause fluid retention and edema. ■ Use caution in patients with pre-existing asthma, especially aspirin-sensitive asthma. Severe bronchospasm has been reported.

Monitor:

Correct hypovolemia before giving ketorolac and maintain adequate hydration. ■ Observe patient frequently, especially for heartburn or signs and symptoms of GI upset or bleeding, and monitor vital signs. ■ Monitor BUN, SCr, liver enzymes, occult blood loss, urinalysis, urine output, and signs of pain relief (e.g., increased appetite and activity). ■ Observe closely during ambulation. ■ Low doses of narcotics may be required to treat breakthrough pain.

Patient Education:

Side effects have resulted in extended hospitalization and could be fatal. ■ Discard any remaining oral ketorolac at end of 5-day total cumulative maximum time for use.

Maternal/Child:

See Contraindications. ■ Category C: safety for use not established. Use only if other alternatives are not available. ■ Discontinue breast-feeding. ■ Multiple dose treatment in pediatric patients has not been studied; limited data available.

Elderly:

See Dose Adjustments and Precautions. ■ More sensitive to side effects. ■ Incidence of GI bleeding and acute renal failure increases with age.

DRUG/LAB INTERACTIONS

Probenecid inhibits clearance and may triple plasma levels of ketorolac. Concomitant use is contraindicated. ■ Potentiated by **salicylates** (especially high-dose regimens). May double plasma levels of ketorolac. Reduce dose of ketorolac by half. ■ May decrease clearance and increase toxicity of **methotrexate.** ■ Additive if used with other **NSAIDs** (see Contraindications); side effects may increase markedly. ■ May potentiate **lithium** levels. ■ May increase risk of bleeding, especially from the GI tract, when given concomitantly with **anticoagulants** or **thrombolytic agents**. ■ May increase risk of bleeding when given with **agents that may cause thrombocytopenia or inhibit or interfere with platelet aggregation** (e.g., clopidogrel, valproic acid) and **serotonin reuptake inhibitors**. ■ Can precipitate renal failure concomitantly with **diuretics**; see Precautions. ■ Can reduce response to **furosemide or other diuretics** in normovolemic healthy individuals. ■ May increase risk of renal impairment with **ACE inhibitors** (e.g., enalapril). ■ Nephrotoxicity of both agents may be increased with **other nephrotoxic agents** (e.g., aminoglycosides, cyclosporine). ■ May potentiate **nondepolarizing muscle relaxants**. ■ Has caused seizures in a few patients taking **antiepileptics**. ■ May cause hallucinations with **antipsychotics or antidepressants**. ■ May cause **elevations of liver function tests** AST and ALT.

SIDE EFFECTS

Average dose:

Diarrhea, dizziness, dyspepsia, drowsiness, edema, GI bleeding, GI pain, headache, injection site pain, nausea, and sweating are most common. Capable of all side effects of other NSAIDs, especially with extended use: abnormal taste, abnormal vision, asthenia, asthma, confusion, constipation, depression, dry mouth, dyspnea, euphoria, excessive thirst, flatulence, inability to concentrate, insomnia, liver function abnormalities, melena, myalgia, nervousness, oliguria, pallor, paresthesia, peptic ulcer, rectal bleeding, stimulation, stomatitis, pruritus, purpura, urinary frequency, urticaria, vasodilation, vertigo, vomiting.

Overdose:

Abdominal pain, diarrhea, labored breathing, metabolic acidosis, pallor, peptic ulcer, rales, vomiting.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly if indicated. Treat anaphylaxis with epinephrine, diphenhydramine, and corticosteroids as indicated. Not significantly cleared by dialysis.

KANAMYCIN SULFATE BBW

(kan-ah-**MY**-sin **SUL**-fayt)
Antibacterial
(aminoglycoside)

pH 4.5

USUAL DOSE

Up to 15 mg/kg of body weight/24 hr equally divided into 2 or 3 doses (7.5 mg/kg every 12 hours or 5 mg/kg every 8 hours). Dosage based on ideal body weight.

Do not exceed a total adult dose of 1.5 Gm by all routes in 24 hours.

PEDIATRIC DOSE

See Maternal/Child.

One source recommends 15 to 30 mg/kg/24 hr in equally divided doses every 12 hours (7.5 to 15 mg/kg every 12 hours). Maximum dose is 1.5 Gm.

DOSE ADJUSTMENTS

Reduce daily dose for renal impairment or increase intervals between injections. ■ Reduced dose or extended intervals may be required in the elderly. ■ See Monitor and Drug/Lab Interactions.

DILUTION

Each 500 mg or fraction thereof must be diluted with at least 100 mL of D5W, D5NS, or NS for infusion, or see chart on inside back cover. Discard partially used vials after 48 hours.

Storage:

Store at CRT.

COMPATIBILITY

Manufacturer states, “Do not physically premix with other drugs; administer separately.” Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities.** See Drug/Lab Interactions.

RATE OF ADMINISTRATION

Give total dose over 30 to 60 minutes.

ACTIONS

An aminoglycoside antibiotic with neuromuscular blocking action. Bactericidal against many gram-negative organisms resistant to other antibiotics. Well distributed through all body fluids; crosses the placental barrier. Usual half-life is 2 to 3 hours. Half-life is prolonged in infants, postpartum females, fever, liver disease and ascites, spinal cord injury, cystic fibrosis, and the elderly; shorter in severe burns. Excreted in high concentrations through the kidneys. Secreted in breast milk.

Cross-allergenicity does occur between aminoglycosides.

INDICATIONS AND USES

Short-term treatment of serious infections caused by susceptible organisms. ■ Concurrent therapy with a penicillin or cephalosporin sometimes indicated. ■ Primarily used when penicillin and other less toxic antibiotics are ineffective or contraindicated.

Unlabeled uses:

Treatment of *Mycobacterium avium* complex, a common infection in AIDS (part of a multiple drug [3 to 5] regimen).

CONTRAINDICATIONS

Known kanamycin or aminoglycoside sensitivity or toxic reaction; see Precautions. Sulfite sensitivity may be a contraindication. Not indicated for treatment in long-term therapy (e.g., tuberculosis) because of the toxic hazard associated with extended administration.

PRECAUTIONS

Most frequently given IM. ■ Use extreme caution if therapy required over 7 to 10 days. ■ Sensitivity studies necessary to determine susceptibility of causative organism to kanamycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, kanamycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ Cross-sensitivity reactions and cumulative effects have been reported with aminoglycosides. ■ Risk of severe ototoxic and nephrotoxic reactions increased in patients with pre-existing renal damage or in normal renal function with prolonged use or high doses. Partial or total irreversible deafness may continue to develop after kanamycin discontinued. ■ The major toxic effects of kanamycin are its actions on the auditory and vestibular branches of the eighth nerve and on the renal tubules. Neurotoxicity manifested by bilateral auditory toxicity (which often is permanent) and sometimes by vestibular ototoxicity. Loss of high frequency perception usually occurs before a noticeable clinical hearing loss. S/S of neurotoxicity include dizziness, hearing loss, roaring in the ears, tinnitus, and vertigo. Convulsions, muscle twitching, numbness, skin tingling, and vertigo may occur with vestibular injury. Risk of neurotoxicity increases with exposure to either high-peak or high-trough serum concentrations and continues to progress after drug withdrawal. ■ Use caution in pediatric patients and elderly. Advanced age and dehydration may increase the risk of toxicity. ■ Use caution in patients with neuromuscular disorders (e.g., myasthenia gravis, parkinsonism, or infant botulism); may aggravate muscle weakness. ■ May contain sulfites; use caution in patients with asthma. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with kanamycin.

Monitor:

Watch for decrease in urine output; decreased urine specific gravity; the presence of cells or casts; oliguria; proteinuria; rising BUN, NPN, and SCr; and declining CrCl. Dose adjustments or discontinuation of kanamycin may be required. ■ Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations to avoid peak serum concentrations above 35 mcg/mL (30 to 90 minutes after injection) and trough concentrations above 10 mcg/mL (just before the next dose). ■ Maintain good hydration. ■ Closely monitor renal and eighth cranial nerve function, especially in patients with known or suspected reduced renal function at onset of therapy and in patients who develop signs of renal dysfunction during therapy. Baseline and serial audiograms are recommended, particularly in high-risk patients. ■ In extended treatment, frequent monitoring of serum levels, electrolytes, and renal, auditory, and vestibular functions is recommended. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly dizziness, hearing loss, weakness, or any changes in balance. ■ Consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category D: avoid pregnancy. Use during pregnancy and breast-feeding only when absolutely necessary. Potential hazard to fetus. ■ Rarely used IV in infants. Use extreme caution in premature infants and neonates; immature kidney function will result in prolonged half-life.

Elderly:

Consider less toxic alternatives. ■ Half-life prolonged. ■ Longer intervals between doses may be more important than reduced doses. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ Advanced age and dehydration may increase the risk of toxicity. ■ See Precautions.

DRUG/LAB INTERACTIONS

Inactivated in solution with **penicillin** but is synergistic when used in combination with **beta-lactam antibiotics and vancomycin.** Do not mix in the same solution. Dose adjustment and appropriate spacing required because of physical **incompatibilities** and interactions. Synergism may be inconsistent; measure aminoglycoside levels. ■ Concurrent and/or sequential use topically or systemically with any other **neurotoxic or nephrotoxic agents** should be avoided, particularly all other aminoglycosides including paromomycin, amphotericin B, bacitracin, cisplatin, colistin, and vancomycin. Toxicity may be additive. ■ Increased nephrotoxicity has been reported with concomitant use of an aminoglycoside antibiotic and some cephalosporins. ■ Neuromuscular blockade and respiratory paralysis can occur if aminoglycosides are administered by any route, especially in patients receiving **anesthetics** (e.g., enflurane), **neuromuscular-blocking muscle relaxants** (e.g., atracurium, succinylcholine), or massive **transfusions** of citrate-anticoagulated blood. ■ Avoid concurrent use with potent diuretics (e.g., ethacrynic acid, furosemide, mannitol). Ototoxicity may be additive. Diuretics may alter antibiotic concentrations in serum and tissue and increase toxicity. ■ Aminoglycosides are also potentiated by **anticholinesterases** (e.g., edrophonium), **antineoplastics** (e.g., nitrogen mustard, cisplatin). ■ **Digoxin** dose may need adjustment. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); bactericidal action may be impacted.

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, in dehydrated or elderly patients, and in patients receiving other ototoxic or nephrotoxic drugs. Nephrotoxicity (albuminuria; azotemia; decrease in creatinine clearance; increased serum creatinine and/or BUN; presence of casts, cells, and protein in urine; oliguria), neuromuscular blockade (acute muscular paralysis, apnea), ototoxicity (acute Ménière's syndrome; cochlear damage; nausea and vomiting; nystagmus; partially reversible or irreversible bilateral loss of hearing, loss of balance, or both; tinnitus; vertigo) are most serious. CDAD, diarrhea, fever, headache, paresthesias, seizures, skin rash, thrombophlebitis have been reported in some patients. "Malabsorption syndrome" (increase in fecal fat, decrease in serum carotene and xylose absorption) has been reported with prolonged therapy.

ANTIDOTE

Notify the physician of all side effects. If minor symptoms persist or any major symptom appears, discontinue the drug and notify the physician. Treatment is symptomatic, or dose adjustment or discontinuation of kanamycin may be required. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. In overdose or toxic reactions, hemodialysis or peritoneal dialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Consider exchange transfusion in the newborn. Calcium salts may reverse neuromuscular blockade. Resuscitate as necessary.

L

LABETALOL HYDROCHLORIDE

(lah-**BET**-ah-lohl hy-droh-**KLOR**-eyed)
Alpha/beta-adrenergic blocking agent
Antihypertensive
pH 3 to 4.5

USUAL DOSE

Dose must be individualized based on degree of hypertension and patient response.

20 mg as an initial dose by IV injection. May repeat with injections of 40 to 80 mg at 10-minute intervals until desired BP is achieved, or may be diluted and given as a continuous infusion. Usually effective with 50 to 200 mg. Do not exceed a total dose of 300 mg. Initiate oral labetalol after desired BP has been achieved and the supine diastolic pressure starts to rise. See literature for dose regimen. AHA recommends 10 mg IV over 1 to 2 minutes. May repeat or double dose every 10 minutes to a maximum dose of 150 mg. Or initial dose may be given by IV injection followed by an infusion of 2 to 8 mg/min. Titrate slowly to achieve desired results without exceeding maximum dose.

DOSE ADJUSTMENTS

See Precautions and Drug/Lab Interactions.

DILUTION

IV injection:

May be given undiluted in a 5 mg/mL concentration.

Continuous infusion:

May be diluted in most commonly used IV solutions (see chart on inside back cover). Addition of 200 mg (40 mL) to 160-mL solution yields 1 mg/mL, 300 mg (60 mL) to 240 mL yields 1 mg/mL, or 200 mg (40 mL) to 250 mL yields 2 mg/3 mL. Amount of solution may be decreased if required by fluid restrictions of the patient.

Storage:

Store unopened vial between 2° and 30° C (36° and 86° F). Do not freeze. Protect from light. Stable after dilution for 24 hours at room temperature or refrigerated.

COMPATIBILITY

Manufacturer lists 5% sodium bicarbonate as **incompatible** and indicates to use care when administering alkaline drugs, including furosemide.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 20 mg or fraction thereof over at least 2 minutes.

Continuous infusion:

Begin at 2 mg/min. Adjust according to orders of physician and BP response. Another source suggests 0.5 to 2 mg/min. Use of a microdrip (60 gtt/mL) or an infusion pump may be helpful.

ACTIONS

An adrenergic receptor blocking agent with both selective alpha-1-adrenergic and nonselective beta-adrenergic receptor blocking activity. Causes dose-related falls in BP without reflex tachycardia or significant reduction in HR. Maximum effect of each dose is reached in 5 minutes. Half-life is 5.5 hours, but some effects last up to 16 hours. Metabolized and excreted as metabolites in urine and through bile to feces. Crosses the placental barrier. Present in small amounts in breast milk.

INDICATIONS AND USES

Control of BP in severe hypertension.

Unlabeled uses:

Treatment of clonidine withdrawal hypertension. ■ Decrease BP and relieve symptoms in patients with pheochromocytoma.

CONTRAINDICATIONS

Obstructive airway disease including asthma, cardiogenic shock, greater than first-degree heart block, overt cardiac failure, severe bradycardia, other conditions associated with severe and prolonged hypotension, and hypersensitivity to labetalol or its components.

PRECAUTIONS

Use caution in impaired liver function. ■ Hepatic injury has been reported. Has occurred after both short-term and long-term treatment. Usually reversible, but hepatic necrosis and death have been reported. ■ Use extreme caution in patients with any degree of cardiac failure; may further depress myocardial contractility. Does not alter effectiveness of digoxin on heart muscle. ■ Effective in lowering BP in pheochromocytoma but has caused a paradoxical hypertensive response in some patients. ■ Use with extreme caution in diabetics or patients with a history of hypoglycemia. May mask the symptoms of hypoglycemia and reduce the release of insulin in response to hyperglycemia. ■ Routine withdrawal of chronic beta-blocker therapy before surgery is not recommended. However, the effect of the alpha-adrenergic activity of labetalol has not been evaluated in the surgical setting. Deaths have occurred when labetalol has been used during surgery. ■ Intraoperative floppy iris syndrome has been observed during cataract surgery in some patients treated with alpha-1 blockers. Characterized by a combination of a flaccid iris, progressive miosis despite preoperative dilation with standard mydriatic drugs, and potential prolapse of the iris. Modification of the surgical technique may be required. ■ See Drug/Lab Interactions.

Monitor:

Keep patient supine. Postural hypotension can occur for up to 3 hours after administration. Ambulate with care and assistance. ■ Monitor BP before and 5 and 10 minutes after each direct IV injection. Monitor at least every 5 minutes during infusion. Avoid rapid or excessive falls in either systolic or diastolic BP. When severely elevated BP drops too rapidly, catastrophic reactions can occur (e.g., cerebral infarction, optic nerve infarction, angina, ischemic ECG changes). ■ Monitor for S/S of CHF. ■ Although rebound angina, myocardial infarction, or ventricular arrhythmias have not been a problem with labetalol, it is recommended that the dose of beta-adrenergic blockers be reduced gradually to avoid these conditions. ■ See Drug/Lab Interactions.

Patient Education:

Report cough, dizziness, irregular pulse, or shortness of breath promptly. ■ May cause dizziness or fainting; request assistance with ambulation.

Maternal/Child:

Category C: use in pregnancy only when clearly indicated and benefit outweighs risk. Hypotension, bradycardia, hypoglycemia, and respiratory depression have been reported in infants of mothers who were treated with labetalol for hypertension during pregnancy. Has been used during labor and delivery. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Use with caution in age-related peripheral vascular disease; risk of hypothermia increased. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Amiodarone may enhance the bradycardic effect of beta-blockers. ■ Inhibits **beta-agonist bronchodilators** (e.g., albuterol); increased doses may be required, especially in patients with asthma. ■ Synergistic with **halothane anesthesia**. ■ Potentiated by **cimetidine**. ■ May blunt the reflex tachycardia produced by **nitroglycerin.** May cause further hypotension with **nitroglycerin.** ■ The use of labetalol with **calcium channel blockers** may potentiate both drugs and result in severe depression of myocardium, AV conduction, and severe hypotension. ■ May mask the hypoglycemic effects of **insulin and other antidiabetic agents.** May inhibit the mobilization of glucose from hepatic stores. Monitor glucose carefully in diabetic patients. ■ Patients receiving beta-blockers who have a history of severe anaphylactic reaction to a variety of allergens may be unresponsive to the usual doses of **epinephrine** used to treat an allergic reaction. ■ May interfere with lab tests in the **diagnosis of pheochromocytoma.** ■ May cause a **false-positive urine test** for amphetamine use.

SIDE EFFECTS

Diaphoresis, dizziness, flushing, moderate hypotension, numbness, severe postural hypotension, nausea, somnolence, tingling of scalp, and ventricular dysrhythmias (e.g., intensified atrioventricular block) occur most frequently.

ANTIDOTE

Notify the physician of all side effects. Decrease rate or discontinue drug if hypotension occurs. Notify physician immediately. Trendelenburg position may be appropriate. May require treatment with IV fluids or vasopressors (e.g., norepinephrine, dopamine). Use atropine or epinephrine for severe bradycardia; digoxin, diuretics, dopamine, or dobutamine for cardiac failure; norepinephrine for hypotension; epinephrine and/or albuterol for bronchospasm; and diazepam for seizures. Unresponsive hypotension and bradycardia may be reversed by glucagon 5 to 10 mg over 30 seconds followed by a continuous infusion of 5 mg/hr. Reduce rate as condition improves. Treat other side effects symptomatically and resuscitate as necessary. Hemodialysis is not effective.

LACOSAMIDE

(la-**KOE**-sa-mide)
Vimpat
Anticonvulsant
pH 3.5 to 5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Serum levels similar by oral or IV route; no dose or frequency adjustment is necessary. Transfer to oral therapy as soon as practical. Twice-daily IV infusions have been used for up to 5 days.

Monotherapy:

Begin with an initial dose of 100 mg twice daily (200 mg/day); dose should be increased by 50 mg twice daily (100 mg/day) every week up to a recommended maintenance dose of 150 to 200 mg twice daily (300 to 400 mg/day). Alternatively, lacosamide may be initiated with a single loading dose of 200 mg* followed approximately 12 hours later by 100 mg twice daily (200 mg/day); this dose regimen should be continued for 1 week. Based on individual response and tolerability, the dose can be increased at weekly intervals by 50 mg twice daily (100 mg/day) until the recommended maintenance dose of 150 to 200 mg twice daily (300 to 400 mg/day) is achieved. For patients who are already on a single antiepileptic and are converting to lacosamide monotherapy, the therapeutic dose of 150 to 200 mg twice daily should be maintained for at least 3 days before initiating withdrawal of the concomitant antiepileptic drug. A gradual withdrawal of the concomitant antiepileptic drug over at least 6 weeks is recommended.

Adjuvant therapy:

Begin with an initial dose of 50 mg twice daily (100 mg/day). Based on individual patient response and tolerability, the dose may be increased at weekly intervals by 50 mg twice daily (100 mg/day). The recommended maintenance dose is 100 to 200 mg twice daily (200 to 400 mg/day). Alternatively, lacosamide may be initiated with a single loading dose of 200 mg* followed approximately 12 hours later by 100 mg twice daily (200 mg/day); this dose regimen should be continued for 1 week. Based on individual response and tolerability, the dose can be increased at weekly intervals by 50 mg twice daily (100 mg/day) as needed until the maximum recommended maintenance dose of 200 mg twice daily (400 mg/day) is achieved.

*Monotherapy and adjuvant therapy:

The loading dose should be administered with medical supervision because of the increased incidence of CNS adverse reactions. There is no evidence that doses greater than 400 mg/day offer additional benefit, and they have been associated with a higher incidence of side effects.

Transfer from an IV dose to an oral dose:

Transfer at the equivalent daily dose and frequency of the IV dose.

DOSE ADJUSTMENTS

Titrate dose with caution in patients with renal or hepatic impairment and in the elderly. ■ No dose adjustment is indicated for patients with mild to moderate renal impairment. ■ 300 mg is the maximum recommended dose for patients with severe renal impairment (a CrCl equal to or less than 30 mL/min) and for patients with end-stage renal disease. A supplemental dose of up to 50% should be considered after a 4-hour hemodialysis treatment. ■ A maximum dose of 300 mg/day is recommended for patients with mild or moderate hepatic impairment. ■ Not recommended for patients with severe hepatic impairment. ■ Patients with renal or hepatic impairment who are taking strong inhibitors of CYP3A4 and CYP2C9 may have a significant increase in exposure of lacosamide. Consult with pharmacist. Dose reduction may be required. ■ Dose adjustment not required based on gender or race or in the elderly; see Elderly.

DILUTION

Available as a 200 mg/20 mL (10 mg/mL) solution for injection.

May be given undiluted or may be further diluted with NS, D5W, or LR. See Rate of Administration.

Filters:

Specific information not available.

Storage:

Store unopened vials at CRT. Do not freeze. Diluted solutions should not be stored for more than 4 hours at RT. Discard unused portions of vial.

COMPATIBILITY

Solutions:

Compatible with NS, D5W, and LR. Additional information not available; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over 30 to 60 minutes is preferred. When medically necessary, may be infused over 15 minutes. Incidence of CNS side effects (e.g., dizziness, paresthesia, and somnolence) may be higher with the 15-minute infusion.

ACTIONS

An antiepileptic (anticonvulsant) drug. The precise mechanism of action is unknown. In vitro studies have shown that it selectively enhances the slow inactivation of voltage-gated sodium channels, resulting in stabilization of hyperexcitable neuronal membranes and inhibition of repetitive neuronal firing. Some effects are reached at the end of infusion. Steady-state plasma concentrations are achieved after 3 days of administration. Doses above 400 mg/day do not appear to have additional benefit. Less than 15% bound to plasma proteins. Partially metabolized. Half-life is approximately 13 hours. Excreted as metabolites and as unchanged drug in urine.

INDICATIONS AND USES

Monotherapy or adjunctive therapy in the treatment of partial-onset seizures in adult patients (17 years of age and older) with epilepsy. IV injection is used as a temporary alternative to oral therapy. May be used alone or in combination with other antiepileptic drugs (AEDs).

CONTRAINDICATIONS

Manufacturer indicates none; see Precautions.

PRECAUTIONS

For IV use only. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. In an analysis of AED clinical trials, symptoms occurred as early as 1 week after starting AEDs and persisted for the duration of treatment. May require a dose reduction or discontinuation of lacosamide. Many illnesses for which AEDs are prescribed, including epilepsy, are associated with morbidity and mortality and an increased risk of suicidal thoughts and behavior. Consider that these symptoms may also be related to the illness being treated. ■ May cause dizziness and ataxia. Dizziness was the adverse event most frequently leading to discontinuation of therapy. Onset of symptoms commonly observed during titration. ■ Dose-dependent prolongations in PR intervals have been observed. AV heart block, bradycardia, and ventricular tachyarrhythmias have been reported. Use caution in patients with underlying proarrhythmic conduction problems such as known conduction problems (e.g., marked first-degree AV block, second-degree or higher AV block, and sick sinus syndrome without a pacemaker), sodium channelopathies (e.g., Brugada syndrome), or severe cardiac disease such as myocardial ischemia, heart failure, or structural heart disease. ■ May cause atrial arrhythmias (atrial fibrillation or atrial flutter), especially in patients with diabetic neuropathy or cardiovascular disease. ■ Syncope or loss of consciousness was reported. Often associated with changes in orthostatic hypotension, atrial flutter/fibrillation (and associated tachycardia), or bradycardia. Most commonly seen in patients with a history of risk factors for cardiac disease, in patients receiving medications that slow AV conduction, and in patients with diabetic neuropathy. Most cases were associated with doses above the recommended 400 mg/day. ■ Drug reaction with eosinophilia and systemic symptoms (DRESS), also known as multiorgan hypersensitivity, has been reported. Usually presents with fever, rash, lymphadenopathy, and/or facial swelling in association with other organ system involvement such as hematologic abnormalities, hepatitis, nephritis, myocarditis, or myositis. Eosinophilia is often present. Deaths have been reported. S/S of early hypersensitivity (e.g., fever, lymphadenopathy) may be present even though a rash is not evident. If S/S appear, evaluate patient and discontinue lacosamide if an alternative etiology for the S/S cannot be established. ■ Not recommended for patients with severe hepatic impairment. ■ To minimize the potential for increased seizure frequency, withdraw AEDs (including lacosamide) gradually (over a minimum of 1 week). ■ Physical dependence has not been demonstrated; however, psychological dependence cannot be excluded because of the ability of lacosamide to produce a euphoria-type response.

Monitor:

Baseline CBC, CrCl, bilirubin, and liver function tests indicated; monitor as needed. ■ Monitor vital signs. ■ Monitor for seizure activity. ■ Monitor for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. ■ Observe patient closely for signs of CNS side effects, prolonged PR interval, and/or symptoms of DRESS; see Precautions. ■ Obtain a baseline ECG in patients with known underlying proarrhythmic conditions or concomitant medications that affect cardiac conduction. Repeat ECG after lacosamide is titrated to steady-state concentrations.

Patient Education:

Read patient information guide provided by manufacturer. ■ May cause dizziness, fainting, and somnolence; use caution performing tasks that require alertness (e.g., operating machinery, driving). ■ Inform your health care professional if you are pregnant or breast-feeding. ■ May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ Has caused atrial arrhythmias. Promptly report palpitations, rapid pulse, and/or shortness of breath. ■ May cause various degrees of heart block. Report slow or irregular pulse, light-headedness, chest pain, or fainting. ■ Promptly report S/S of hypersensitivity (e.g., fever, rash) or liver toxicity (e.g., fatigue, jaundice, dark urine). ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry. ■ Review prescription and nonprescription drugs with your physician.

Maternal/Child:

Animal studies demonstrated developmental toxicity (increased embryofetal and perinatal mortality, growth deficit). Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. Manufacturer has established a pregnancy registry to evaluate safety and outcomes; see manufacturer's literature and Patient Education. ■ Effects during labor and delivery unknown. ■ No data on the presence of lacosamide in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients under 17 years of age not established.

Elderly:

Higher plasma concentrations seen in the elderly may be due to differences in total body water and age-associated impaired renal function. Although dose adjustment based on age is not necessary, dose titration should be performed with caution; see Usual Dose.

DRUG/LAB INTERACTIONS

Use with caution in patients taking concomitant **medications that affect cardiac conduction** (e.g., beta-blockers, calcium channel blockers), potassium channel blockers, sodium channel blockers, and medications that prolong the PR interval. Increased risk of AV block, bradycardia, and ventricular tachyarrhythmia. Baseline ECG and repeat ECG following titration to steady state recommended. ■ No evidence of any relevant drug/drug interaction with **other antiepileptic drugs**. ■ Patients with renal or hepatic impairment who are taking **strong inhibitors of CYP3A4** (e.g., ritonavir, clarithromycin, ketoconazole) **and CYP2C9** (e.g., fluconazole) may have a significant increase in exposure of lacosamide. Dose reduction may be necessary.

SIDE EFFECTS

The most common side effects are diplopia, dizziness, headache, and nausea. Ataxia, blurred vision, diplopia, dizziness, nausea, vertigo, and vomiting led to discontinuation of lacosamide. Incidence of side effects increased with doses above 400 mg/day. Most side effects at recommended doses were considered mild or moderate and included abnormal coordination; anemia; asthenia; balance disorder; cerebellar syndrome; chest pain; confusion; constipation; depression; diarrhea; dry mouth; dyspepsia; elevated liver function tests (e.g., ALT, AST); falls; fatigue; feeling drunk; fever; gait disturbance;

hyperhidrosis; hypoanesthesia; injection site pain, discomfort, irritation, or erythema; muscle spasms; nystagmus; oral hypoanesthesia; palpitations; paresthesia; pruritus; skin laceration; somnolence; tinnitus; and tremor. Psychiatric disorders, including aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hallucinations, hostility, irritability, and suicidal tendencies, have been reported. May produce euphoria-type reactions. Other serious adverse reactions include ataxia and dizziness, cardiac rhythm and conduction abnormalities, multiorgan hypersensitivity reactions, and syncope.

Post-Marketing:

Aggression, agitation, agranulocytosis, angioedema, hallucinations, insomnia, new or worsening seizures, psychotic disorder, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria.

ANTIDOTE

Keep physician informed of all side effects. Some may not require intervention, and others may improve with a reduced dose or discontinuation of lacosamide; see Precautions and Side Effects. Discontinue lacosamide for symptoms of DRESS; use of an alternate treatment is recommended. Support patient as required in treatment of overdose. No specific antidote in overdose; however, hemodialysis will remove approximately 50% of a dose in 4 hours.

LARONIDASE BBW

(lah-**RON**-ih-daze)
Aldurazyme
Enzyme replenisher
pH 5.5

USUAL DOSE

Premedication:

Pretreatment with antipyretics (e.g., acetaminophen) and/or antihistamines (e.g., diphenhydramine) is recommended and should be given 60 minutes before starting the infusion. All patients in the initial clinical studies were treated with both antipyretics and antihistamines. See Monitor.

Laronidase:

0.58 mg/kg of body weight as an infusion once each week.

PEDIATRIC DOSE

Pediatric patients 5 years of age or older:

See Usual Dose. Pediatric patients younger than 5 years were not included in clinical trials.

DOSE ADJUSTMENTS

None indicated.

DILUTION

Each vial contains 2.9 mg of laronidase in 5 mL (0.58 mg/mL). Determine the number of vials needed to provide the calculated dose. Dose in mg (0.58 mg/kg) equals the drug concentration (0.58 mg/mL), so the total dose in milliliters of laronidase required is equal to the patient's weight in kg multiplied by 1 mL/kg. The number of vials needed is calculated by dividing the total required dose in milliliters by 5 (the number of mL in a vial). For example, an 80-kg patient would receive 80 mL (80 kg × 1 mL/kg = 80 mL). 80 mL ÷ 5 mL/vial = 16 vials. Round up to the nearest whole vial. Allow vials to reach room temperature. Do not heat or microwave vials. Solution should be clear or have a few translucent particles. ***Must be further diluted by a specific three-step process that includes 0.1% albumin (human) and NS. Total final volume of the infusion is based on patient weight. Total final volume should be 100 mL for patients weighing less than or equal to 20 kg or 250 mL for patients weighing more than 20 kg.***

Begin with a PVC infusion bag of NS (100 or 250 mL), a vial of 5% or 25% albumin (human), and the number of vials of room temperature laronidase required.

Using the following chart, prepare an infusion bag of 0.1% albumin in NS. Remove and discard a volume of NS equal to the required volume of albumin to be added. Add the appropriate volume of albumin and gently rotate the infusion bag to ensure proper distribution of the albumin.

Total Volume of Laronidase Infusion	Volume of Albumin (Human) 5% to Be Added	Volume of Albumin (Human) 25% to Be Added
100 mL	2 mL	0.4 mL
250 mL	5 mL	1 mL

Next, withdraw and discard a volume of this combined solution (0.1% albumin and NS) from the infusion bag equal to the volume of laronidase required (a total of 80 mL in the previous example).

Next, slowly withdraw the calculated volume of laronidase from the appropriate number of vials (a total of 16 vials in the previous example) and slowly add it to the 0.1% albumin and NS solution. ***Do not use a filter needle when withdrawing laronidase from the vials or adding laronidase into the albumin/NS solution (may cause agitation).*** Do not shake. Avoid all excessive agitation, because it may make the laronidase biologically inactive. Gently rotate the infusion bag to ensure proper distribution.

Filters:

Do not use a filter needle when withdrawing laronidase from the vials or adding laronidase into the albumin/NS solution (may cause agitation). Fully diluted solution should be administered with a PVC infusion set equipped with an in-line, low–protein-binding, 0.2-micron filter.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not use after the expiration date on the vial. Immediate use of the diluted solution is preferred but, if necessary, it may be refrigerated. No more than 36 hours should elapse between preparation of the solution and completion of the infusion. Discard unused laronidase.

COMPATIBILITY

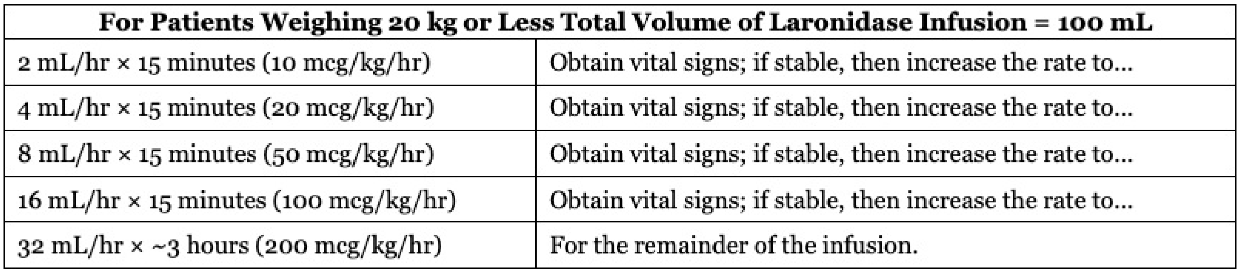
Manufacturer states, “Must not be mixed with other medicinal products in the same solution.” Use of PVC containers and infusion sets recommended; **compatibility** with glass containers not established.

RATE OF ADMINISTRATION

Fully diluted solution should be administered with a PVC infusion set equipped with an in-line, low–protein-binding, 0.2-micron filter. Infusion reactions may occur even when patients have been premedicated.

Initial infusion rate:

10 mcg/kg/hr is the maximum initial infusion rate. Should an infusion reaction occur, further decrease this rate or discontinue until symptoms subside. Additional premedication may be indicated. If an infusion reaction does not occur, the infusion rate may be increased every 15 minutes during the first hour and then as tolerated until a maximum infusion rate of 200 mcg/kg/hr is reached. The maximum rate may be maintained for the remainder of the infusion. Total volume of the infusion is determined by the patient’s body weight and should be delivered over 3 to 4 hours. See the following charts for suggested increments based on volume and suggested monitoring criteria.



For Patients Weighing 20 kg or Less Total Volume of Laronidase Infusion = 100 mL	
2 mL/hr × 15 minutes (10 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
4 mL/hr × 15 minutes (20 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
8 mL/hr × 15 minutes (50 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
16 mL/hr × 15 minutes (100 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
32 mL/hr × ~3 hours (200 mcg/kg/hr)	For the remainder of the infusion.

For Patients Weighing More Than 20 kg Total Volume of Laronidase Infusion = 250 mL	
5 mL/hr × 15 minutes (10 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
10 mL/hr × 15 minutes (20 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
20 mL/hr × 15 minutes (50 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
40 mL/hr × 15 minutes (100 mcg/kg/hr)	Obtain vital signs; if stable, then increase the rate to...
80 mL/hr × ~3 hours (200 mcg/kg/hr)	For the remainder of the infusion.

ACTIONS

A recombinant form of the human enzyme, alpha-L-iduronidase; produced by genetic engineering. Mucopolysaccharide storage disorders are caused by the deficiency of specific lysosomal enzymes required for the catabolism of glycosaminoglycans (GAG). A deficiency of alpha-L-iduronidase interferes with the hydrolysis of terminal alpha-L-iduronic acid residues, which results in the accumulation of specific GAG substrates throughout the body and leads to widespread cellular, tissue, and organ dysfunction (mucopolysaccharidosis I [MPS I]). Laronidase provides an exogenous enzyme for uptake into lysosomes and increases the catabolism of GAG. Has been shown to improve pulmonary function and walking capacity. Ability to cross the blood-brain barrier and effects on the CNS manifestations of MPS I have not been evaluated. Mean elimination half-life ranges from 1.5 to 3.6 hours.

INDICATIONS AND USES

To reduce the accumulation of specific GAG substrates throughout the body that lead to widespread cellular, tissue, and organ dysfunction in patients with Hurler and Hurler-Scheie forms of MPS I and for patients with the Scheie form who have moderate to severe symptoms.

CONTRAINDICATIONS

Manufacturer states, “No known contraindications.”

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with facilities for monitoring the patient and responding to any medical emergency. ■ Life-threatening infusion and hypersensitivity reactions, including anaphylaxis, have been observed during or up to 3 hours after laronidase infusion and may occur even in patients who have been appropriately premedicated. Patients with MPS I disease may have pre-existing upper airway obstruction and may be at increased risk for more severe infusion reactions; monitor closely. Patients with compromised respiratory function or acute respiratory disease may also be at increased risk; assess clinical condition prior to administration and monitor closely. ■ If a severe hypersensitivity or anaphylactic reaction occurs, consider risk versus benefit before resuming therapy or considering additional infusions. Patients with MPS I disease often have concurrent coronary artery disease; use caution if considering the use of epinephrine to treat anaphylaxis or hypersensitivity reactions. ■ Most patients develop antibodies to laronidase; effects on therapy not known. ■ Risks and benefits of treating mildly affected patients with the Scheie form have not been established. ■ Has been shown to improve pulmonary function and walking capacity. ■ See Drug/Lab Interactions and Antidote.

Monitor:

Monitor V/S frequently; see charts under Rate of Administration. ■ Observe patient continuously for symptoms of infusion-related or hypersensitivity reactions (angioedema, airway obstruction, bronchospasm, cough, dyspnea, fever, flushing, headache, pruritus, rash, urticaria); see Precautions, Drug/Lab Interactions, and Antidote. Frequency may decrease with continued use of laronidase. ■ Monitor patients with compromised respiratory function or acute respiratory disease closely; may be at risk for serious acute exacerbation of their respiratory compromise due to infusion reactions. ■ Numerous other baseline tests and specific monitoring of cardiac, circulatory, and renal function may be indicated based on the degree of progression of each patient's MPS I disease.

Patient Education:

Report early symptoms of an allergic reaction promptly (e.g., flushing, itching, rash, shortness of breath). ■ BioMarin Pharmaceutical has established a registry and encourages all patients to participate to further evaluate the effects of therapy with possible long-term follow-up.

Maternal/Child:

Category B: use during pregnancy only if clearly needed. ■ Effects during breast-feeding unknown; use caution.

Elderly:

Specific information not available. Clinical studies did not include patients 65 years of age or older. Response compared to younger adults unknown.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

The most common infusion-related reactions include fever, flushing, headache, and rash. Abdominal pain, arthralgia, chills, cough, decreased oxygen saturation, diarrhea, dyspnea, hypertension, nausea, pruritus, urticaria, and vomiting have also occurred. Frequency may decrease with continued use of laronidase. Serious infusion-related hypersensitivity reactions have been reported and may include anaphylaxis, angioedema, airway obstruction, bradycardia, bronchospasm, hypotension, hypoxia, respiratory distress or failure, stridor, and tachypnea. Other side effects include injection site reaction or pain and upper respiratory tract infection. Abscess, bilirubinemia, chest pain, corneal opacity, edema (dependent and facial), hyperreflexia, hypotension, paresthesia, thrombocytopenia, and vein disorders have been reported. Relationship to laronidase versus MPS I disease not established.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. If a mild to moderate infusion or hypersensitivity reaction occurs, reduce rate or discontinue laronidase until symptoms subside. Additional antipyretics (e.g., acetaminophen), or antihistamines (e.g., diphenhydramine) may be indicated. With additional premedication and/or a reduction in rate of infusion, patients may be able to continue treatment. If a severe hypersensitivity or anaphylactic reaction occurs, discontinue laronidase immediately and treat as indicated; however, use caution if epinephrine is required due to the prevalence of coronary artery disease in patients with MPS I disease. Resuscitate as necessary.

LEFAMULIN

(le-**FAM**-ue-lin)
Xenleta
Antibacterial (pleuromutilin)
pH 4.5 to 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status.

Lefamulin:

150 mg every 12 hours as an IV infusion over 60 minutes for 5 to 7 days **OR** 600 mg PO every 12 hours for 5 days; see Precautions. May switch to oral therapy at a dose of 600 mg PO every 12 hours to complete a treatment course.

DOSE ADJUSTMENTS

Reduce dose to 150 mg IV every 24 hours in patients with severe hepatic impairment (Child-Pugh Class C). No adjustment is needed for patients with mild (Child-Pugh Class A) or moderate (Child-Pugh Class B) hepatic impairment. ■ No clinically significant differences in pharmacokinetics of lefamulin were observed based on age, gender, race, weight, or renal impairment, including patients receiving hemodialysis.

DILUTION

Lefamulin injection is available as a clear, colorless solution in a single-dose vial containing 150 mg/15 mL (10 mg/mL). It is supplied with a diluent bag containing 250 mL of 10 mM citrate-buffered 0.9% sodium chloride. Dilute the entire 15-mL vial of lefamulin into the supplied diluent bag. Mix thoroughly. Do not use the diluent bag in series connections.

Filter:

Data not available.

Storage:

Store unopened vials under refrigeration at 2° to 8° C (36° to 46° F). ***Do not freeze.*** The diluent bag may be stored at CRT. After dilution, may be stored for up to 24 hours at RT and up to 48 hours when refrigerated at 2° to 8° C (36° to 46° F).

COMPATIBILITY

The manufacturer states, "Do not add other additives to the diluent bag because their **compatibilities** with lefamulin have not been established."

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 60 minutes. Do not exceed the recommended rate of administration; may increase the magnitude of QT prolongation; see Precautions. Do not use the diluent bag in series connections.

ACTIONS

A semi-synthetic systemic pleuromutilin antibacterial that inhibits bacterial protein synthesis through various interactions with the 50S ribosomal subunit. Lefamulin is bactericidal in vitro against *Streptococcus pneumoniae*, *Haemophilus influenzae,* and *Mycoplasma pneumoniae* (including macrolide-resistant strains) and is bacteriostatic against *Staphylococcus aureus* and *Streptococcus pyogenes* at clinically relevant concentrations.

Lefamulin is not active against Enterobacteriaceae and *Pseudomonas aeruginosa*. Plasma protein binding is 94.8% to 97.1%. Lefamulin is primarily metabolized by CYP3A4. The mean elimination half-life is approximately 8 hours (range 3 to 20 hours). Excreted primarily in feces and to a lesser extent in urine.

INDICATIONS AND USES

Treatment of adults with community-acquired bacterial pneumonia (CABP) caused by the following susceptible microorganisms: *S. pneumoniae*, *S. aureus* (methicillin-susceptible isolates), *H. influenzae, Legionella pneumophila*, *M. pneumoniae*, and *Chlamydophila pneumoniae*.

CONTRAINDICATIONS

History of known severe hypersensitivity to lefamulin, pleuromutilin class drugs, or to any component of lefamulin.

PRECAUTIONS

May prolong the QT interval of the electrocardiogram (ECG) in some patients. Avoid use in patients with known prolongation of the QT interval, patients with ventricular arrhythmias (including torsades de pointes), patients receiving Class IA (e.g., quinidine, procainamide) or Class III (e.g., amiodarone) antiarrhythmic agents, or patients receiving other drugs that prolong the QT interval such as antipsychotics, erythromycin, pimozide, moxifloxacin, and tricyclic antidepressants. ■ Use with caution in patients with renal failure who require dialysis and in patients with any degree of hepatic impairment. Metabolic disturbances may lead to QT prolongation; see Monitor. ■ The magnitude of QT prolongation may increase with increasing concentrations of lefamulin or increasing rate of infusion. Do not exceed recommended dose or rate of administration. ■ Specific sensitivity studies indicated to determine susceptibility of causative organism to lefamulin. ■ Some isolates resistant to beta-lactams, glycopeptides, macrolides, mupirocin, quinolones, tetracyclines, and trimethoprim-sulfamethoxazole may be susceptible to lefamulin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, lefamulin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with lefamulin.

Monitor:

Monitor patients with hepatic impairment for adverse reactions associated with lefamulin. ■ Monitor ECG in patients at risk for QT prolongation; see Precautions. ■ Monitoring of electrolytes may be indicated in patients at risk for QT prolongation due to metabolic disturbances related to impaired renal or hepatic impairment.

Patient Education:

Verify pregnancy status. Women of reproductive potential should use effective contraception during treatment and for 2 days after the final dose. The manufacturer has a surveillance program for pregnant women who have inadvertently taken lefamulin during pregnancy; see prescribing information. ■ Review list of medications with provider. ■ Nausea and vomiting are common adverse reactions seen with lefamulin. ■ Promptly report any symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Based on animal studies, lefamulin may cause fetal harm when administered to pregnant women. ■ Because of the potential for serious adverse reactions, including QT prolongation, a woman should pump and discard breast milk for the duration of treatment with lefamulin and for 2 days after the final dose. ■ Safety and efficacy for use in pediatric patients younger than 18 years of age have not been established.

Elderly:

Safety and efficacy are similar to that seen in younger patients.

DRUG/LAB INTERACTIONS

Concomitant use of lefamulin with **strong CYP3A4 inducers or P-gp inducers** (e.g., rifampin) decreases lefamulin AUC and C_{max}, which may reduce the efficacy of lefamulin. Avoid concomitant use unless the benefit outweighs the risks. ■ The pharmacodynamic interaction potential to prolong the QT interval between lefamulin and other drugs that affect cardiac conduction is unknown. Avoid concomitant use of lefamulin with **drugs that can prolong the QT interval** (e.g., Class IA and III antiarrhythmics, antipsychotics, erythromycin, moxifloxacin, tricyclic antidepressants); see Precautions and Monitor. ■ In vitro studies have demonstrated no antagonism between lefamulin and amikacin, azithromycin, aztreonam, ceftriaxone, levofloxacin, linezolid, meropenem, penicillin, tigecycline, trimethoprim/sulfamethoxazole, and vancomycin. ■ Lefamulin has demonstrated synergy in vitro with **doxycycline** against *S. aureus*.

SIDE EFFECTS

The most common adverse reactions include headache, hepatic enzyme elevation, hypokalemia, injection site reactions, insomnia, and nausea. Other reported reactions include abdominal pain, anemia, anxiety, atrial fibrillation, CDAD, constipation, diarrhea, dyspepsia, epigastric discomfort, erosive gastritis, increased creatine phosphokinase, oropharyngeal candidiasis, QT prolongation, palpitations, somnolence, thrombocytopenia, urinary retention, vomiting, and vulvovaginal candidiasis.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated. Mild cases of CDAD may respond to discontinuation of lefamulin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Lefamulin and its primary metabolite are not dialyzable.

LETERMOVIR

(le-**TERM**-oh-vir)
Prevymis
Antiviral
pH 7.5

USUAL DOSE

480 mg PO or IV once daily. Initiate between Day 0 and Day 28 posttransplantation (before or after engraftment) and continue through Day 100 posttransplantation. Reserve IV formulation for patients unable to take oral preparation. Transfer to oral dosing as soon as practical. IV and oral dose may be used interchangeably at the discretion of the physician. No dose adjustment necessary when switching formulations.

DOSE ADJUSTMENTS

If cyclosporine is initiated after starting letermovir, decrease letermovir to 240 mg once daily beginning with the next scheduled dose. ■ If cyclosporine is discontinued after starting letermovir, increase letermovir to 480 mg once daily beginning with the next scheduled dose. ■ If cyclosporine dosing is interrupted due to high cyclosporine levels, no dose adjustment of letermovir is required. ■ No dose adjustment required based on renal impairment for patients with a creatinine clearance (CrCl) greater than 10 mL/min. ■ Data insufficient to make dosing recommendations in patients with CrCl 10 mL/min or less or in patients on dialysis. ■ No dose adjustment required for patients with mild or moderate hepatic impairment. Not recommended for patients with severe hepatic impairment. ■ No dose adjustment indicated based on age, body weight (up to 100 kg), gender, or race.

DILUTION

Available in single-dose vials containing 240 mg/12 mL or 480 mg/24 mL (both are 20 mg/mL). Do not shake the vial. Withdraw the desired dose and add to an IV bag containing 250 mL of NS or D5W; see Compatibility. Mix gently. Do not shake. May be colorless to slightly yellow.

Filters:

Specific information not available.

Storage:

Store single-dose vials at CRT in carton to protect from light. Diluted solutions are stable for up to 24 hours at RT or up to 48 hours under refrigeration (time includes time in storage through completion of the infusion).

COMPATIBILITY

Consider any item NOT listed as compatible to be INCOMPATIBLE.

Manufacturer states, "Should not be coadministered through the same IV line or cannula with other drug products and diluent combinations except those specifically listed."

Compatible With:

IV Bags:

Polyvinyl chloride (PVC), ethylene vinyl acetate (EVA), polyolefin (polypropylene and polyethylene).

Infusion Sets:

PVC, polyethylene (PE), polybutadiene (PBD), silicone rubber (SR), styrene-butadiene copolymer (SBC), styrene-butadiene-styrene copolymer (SBS), polystyrene (PS).

Plasticizers:

Diethylhexyl phthalate (DEHP), tris (2-ethylhexyl) trimellitate (TOTM), benzyl butyl phthalate (BBP).

Catheters:

Radiopaque polyurethane.

Y-site:

Diluted with NS:

Ampicillin, ampicillin/sulbactam, caspofungin, daptomycin, fentanyl citrate, fluconazole, furosemide, human insulin, magnesium sulfate, methotrexate, micafungin.

Diluted with D5W:

Amphotericin B, anidulafungin, cefazolin, ceftaroline, ceftriaxone, doripenem, famotidine, folic acid, ganciclovir, hydrocortisone sodium succinate, morphine, norepinephrine, pantoprazole, potassium chloride, potassium phosphate, tacrolimus, telavancin, tigecycline.

RATE OF ADMINISTRATION

A single dose as an infusion at a constant rate over 1 hour. May be infused via a peripheral catheter or a central venous line.

ACTIONS

Letermovir is an antiviral drug against CMV. It inhibits the CMV DNA terminase complex, which is required for viral DNA processing and packaging. 99% bound to human plasma proteins in vitro. Metabolized in the liver via UGT1A1/1A3. Mean terminal half-life is 12 hours. Primarily eliminated in feces (93%) as unchanged drug (70%) with minimal excretion in urine.

INDICATIONS AND USES

Prophylaxis of cytomegalovirus (CMV) infection and disease in adult CMV-seropositive recipients [R+] of an allogeneic hematopoietic stem cell transplantation (HSCT).

CONTRAINDICATIONS

Patients receiving pimozide or ergot alkaloids. ■ Concomitant use with pitavastatin and simvastatin when coadministered with cyclosporine; see Drug/Lab Interactions.

PRECAUTIONS

Do not administer an IV bolus injection. ■ Concomitant use of letermovir and certain drugs may result in potentially significant drug interactions, which may lead to adverse reactions (letermovir or concomitant drug) or decreased therapeutic effect of letermovir or the concomitant drug; see Contraindications and Drug/Lab Interactions.

Monitor:

See Drug/Lab Interactions for specific monitoring requirements when letermovir is administered with other drugs. ■ See Contraindications. ■ After the completion of letermovir prophylaxis, monitoring for CMV reactivation is recommended. ■ Monitor SCr in patients with a CrCl less than 50 mL/min. Accumulation of the intravenous vehicle (hydroxypropyl betadex) can occur.

Patient Education:

Interacts with many drugs. Report the use of all prescription and nonprescription medications and herbal products to a health care provider.

Maternal/Child:

Data on safety for use in pregnancy not available; benefit must justify potential risks to fetus. ■ There are no data on the presence of letermovir in human milk, the effects on breast-fed infants, or the effects on milk production. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar across older and younger subjects.

DRUG/LAB INTERACTIONS

The following drug interactions apply only to coadministration of letermovir alone (without cyclosporine) unless otherwise noted. The magnitude of letermovir drug interactions on coadministered drugs may be different when letermovir is coadministered with cyclosporine; see cyclosporine monograph.

Potentially Significant Drug Interactions of Letermovir When Administered Without Cyclosporine[a]

Concomitant Drug Class and/or Clearance Pathway and Drug Name	Effect on Concentration	Clinical Comments Suggested When Letermovir Administered With Each Drug
Antiarrhythmic Agents		
Amiodarone	Concentration of amiodarone increased	Monitor closely for amiodarone side effects. Monitor amiodarone concentrations frequently.
Antibiotics		
Nafcillin	Concentration of letermovir decreased	Coadministration not recommended.
Anticoagulants		
Warfarin	Concentration of warfarin decreased	Monitor INR frequently.
Anticonvulsants		
Carbamazepine	Concentration of letermovir decreased	Coadministration not recommended.
Phenobarbital	Concentration of letermovir decreased	Coadministration not recommended.
Phenytoin	Concentration of letermovir decreased Concentration of phenytoin decreased	Coadministration not recommended.

Antidiabetic Agents		
Glyburide, repaglinide, rosiglitazone, others	Concentration of all three agents increased	Monitor glucose concentrations frequently. If letermovir is coadministered with cyclosporine, use of repaglinide is not recommended.
Antifungals		
Voriconazole	Concentration of voriconazole decreased	Monitor closely for reduced effectiveness of voriconazole.
Antimycobacterials		
Rifabutin	Concentration of letermovir decreased	Coadministration not recommended.
Rifampin	Concentration of letermovir decreased	Coadministration not recommended.
Antipsychotics		
Pimozide	Concentration of pimozide increased	Contraindicated due to risk of QT prolongation and torsades de pointes.
Thioridazine	Concentration of letermovir decreased	Coadministration not recommended.
Endothelin Antagonists		
Bosentan	Concentration of letermovir decreased	Coadministration not recommended.
Ergot Alkaloids		
Ergotamine, dihydroergotamine	Concentration of ergot alkaloids increased	Contraindicated due to risk of ergotism.
Herbal Products		
St. John's wort *(Hypericum perforatum)*	Concentration of letermovir decreased	Coadministration not recommended.
HIV Medications		
Efavirenz	Concentration of letermovir decreased	Coadministration not recommended.
Etravirine	Concentration of letermovir decreased	Coadministration not recommended.
Nevirapine	Concentration of letermovir decreased	Coadministration not recommended.
HMG-CoA Reductase Inhibitors		

Atorvastatin	Concentration of atorvastatin increased	Do not exceed an atorvastatin dose of 20 mg daily. Monitor closely for myopathy and rhabdomyolysis. If letermovir is coadministered with cyclosporine, use of atorvastatin is not recommended.
Pitavastatin, simvastatin	Concentration of HMG-CoA reductase inhibitors increased	Coadministration not recommended. Contraindicated if letermovir is coadministered with cyclosporine because of significant increases of concentrations of pitavastatin and simvastatin and risk of myopathy or rhabdomyolysis.
Fluvastatin, lovastatin, pravastatin, rosuvastatin	Concentration of HMG-CoA reductase inhibitors increased	A statin dose reduction may be necessary. Monitor closely for myopathy and rhabdomyolysis. If letermovir is coadministered with cyclosporine, use of lovastatin is not recommended. Refer to the prescribing information for other statins for specific statin dosing recommendations.
Immunosuppressants		
Cyclosporine	Concentration of cyclosporine and letermovir increased	Decrease dose of letermovir to 240 mg once daily. Monitor cyclosporine whole blood concentrations frequently during treatment and after discontinuation of letermovir, and adjust dose of cyclosporine accordingly.
Sirolimus	Concentration of sirolimus increased	Monitor sirolimus whole blood concentrations frequently during treatment and after discontinuation of letermovir, and adjust dose of sirolimus accordingly. If letermovir is coadministered with cyclosporine and sirolimus, refer to the sirolimus prescribing information for specific sirolimus dosing recommendations.
Tacrolimus	Concentration of tacrolimus increased	Monitor tacrolimus whole blood concentrations frequently during treatment and after discontinuation of letermovir, and adjust dose of tacrolimus accordingly.
Proton Pump Inhibitors		
Omeprazole Pantoprazole	Concentration of omeprazole and pantoprazole decreased	Clinical monitoring and dose adjustment may be needed.
Wakefulness-Promoting Agents		
Modafinil	Concentration of letermovir decreased	Coadministration not recommended.
CYP3A Substrates		
Alfentanil, fentanyl, midazolam, quinidine, others	Concentration of CYP3A substrate increased	When letermovir is coadministered with a CYP3A substrate, refer to the prescribing information for dosing of the CYP3A substrate with a moderate CYP3A inhibitor. When letermovir is coadministered with cyclosporine, the combined effect on CYP3A substrates may be similar to a strong CYP3A inhibitor. Refer to the prescribing information for dosing of the CYP3A substrate with a strong CYP3A inhibitor. CYP3A substrates pimozide and ergot alkaloids are contraindicated.

[a] Table is not all-inclusive.

■ Letermovir is an inhibitor of OATP1B1/3 transporters; coadministration with drugs that are substrates of OATP1B1/3 transporters may result in clinically relevant increases in the plasma concentrations of the substrates. ■ If dose adjustments of concomitant medications are made due to treatment with letermovir, doses should be readjusted after treatment with letermovir is completed. Clinically significant interactions were ***not*** observed with acyclovir, digoxin, mycophenolate mofetil, fluconazole, posaconazole, ethinyl estradiol, and levonorgestrel.

SIDE EFFECTS

Abdominal pain, cough, diarrhea, fatigue, headache, nausea, peripheral edema, and vomiting are most common. Cardiac events (atrial fibrillation, tachycardia) have been reported. Laboratory abnormalities include decreased ANC, hemoglobin, and platelets and increased serum creatinine. A hypersensitivity reaction with associated moderate dyspnea occurred in one subject after the first infusion of letermovir, leading to discontinuation. Nausea was the most common reason for drug discontinuation.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. There is no specific antidote for overdose, and the effects of dialysis on removal of letermovir from the systemic circulation are unknown. Monitor drug/drug interactions closely for risk of increased side effects or reduced therapeutic effect. Should a hypersensitivity reaction occur, treat as necessary (e.g., antihistamines, epinephrine, corticosteroids). Resuscitate if indicated.

LEUCOVORIN CALCIUM

(loo-koh-**VOR**-in **KAL**-see-um)
Citrovorum Factor, Folinic Acid, Leucovorin Calcium PF
Antidote
Antineoplastic adjunct
pH 6 to 8.1

USUAL DOSE

May be given IV/IM or PO. If GI toxicity is present, should be administered parenterally.

Delayed excretion or overdose of methotrexate (MTX):

10 mg/M² every 6 hours until the serum MTX level is less than 0.05 micromolar. Milligram for milligram or greater than the dose of MTX is common. Administer within the first hour (or as soon as possible) in overdose or within 24 hours of MTX dose if there is delayed excretion. At least every 24 hours, obtain a SCr and MTX level. If SCr is more than 50% above pretreatment level, increase the leucovorin dose to 100 mg/M² every 3 hours until the serum MTX level is less than 0.05 micromolar.

Leucovorin rescue after high-dose MTX therapy:

With high-dose methotrexate (12 to 15 Gm/M^2 as an infusion over 4 hours), begin leucovorin 15 mg (approximately 10 mg/M^2) 24 hours after MTX infusion started. Repeat every 6 hours for 10 doses. If MTX elimination is delayed, extend every-6-hour dosing until MTX level is less than 0.05 micromolar. If there is evidence of acute renal injury, increase leucovorin to 150 mg every 3 hours until MTX level is less than 1 micromolar, then 15 mg every 3 hours until MTX level is less than 0.05 micromolar. In both situations obtain SCr and MTX level at least every 24 hours. Other protocols are in use. Amount of leucovorin is dependent on MTX dose, MTX serum levels, and SCr.

Megaloblastic anemia:

Up to 1 mg daily.

Advanced colorectal cancer:

200 mg/M^2 followed by fluorouracil (5-FU) 370 mg/M^2 or leucovorin 20 mg/M^2 followed by 5-FU 425 mg/M^2 daily for 5 days. Repeat at 4-week intervals twice, then repeat every 28 to 35 days based on complete recovery from toxic effects. Reduce 5-FU dose based on tolerance to previous course, 20% for moderate hematologic or GI toxicity, 30% for severe. Leucovorin doses remain the same. Increase 5-FU dose 10% if no toxicity. Other protocols are in use. Also approved for use with irinotecan and 5-FU.

Pemetrexed toxicity (unlabeled):

A single dose of 100 mg/M^2. Follow with 50 mg/M^2 every 6 hours for 8 days.

DOSE ADJUSTMENTS

See adjustments in Usual Dose; larger reductions may be required in the elderly based on the potential for decreased renal function, especially in combination with fluorouracil. ■ See Precautions/Monitor.

DILUTION

Each 50-mg, 100-mg, or 350-mg vial should be diluted to a 10 mg/mL to 20 mg/mL solution. For total doses less than 10 mg/M^2, dilute with bacteriostatic water for injection (contains benzyl alcohol as a preservative). Use SWFI without a preservative for any dose 10 mg/M^2 or greater. May be further diluted in 100 to 500 mL of D5W, D10W, NS, R, or LR. 1-mL (3-mg) ampules may be given undiluted (contain benzyl alcohol).

Storage:

If prepared without a preservative, use immediately; stable up to 7 days with a preservative.

COMPATIBILITY

Several sources, including the manufacturer, cite **incompatibility** with fluorouracil (5-FU) as an additive; may form a precipitate.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Because of calcium content, do not exceed a rate of 160 mg/min (16 mL of a 10-mg/mL or 8 mL of a 20-mg/mL solution). May be given more slowly. Large doses may be infused equally distributed over 1 to 6 hours. Never exceed above limits.

ACTIONS

Potent agent for neutralizing immediate toxic effects of methotrexate (and other folic acid antagonists) on the hematopoietic system. Preferentially rescues normal cells without reversing the oncolytic effect of methotrexate. Also enhances the therapeutic and toxic effects of fluoropyrimidines (e.g., fluorouracil).

INDICATIONS AND USES

Treatment of accidental folic acid antagonist (e.g., methotrexate) overdose or delayed excretion of MTX. ■ Folinic acid rescue to prevent or decrease the toxicity of massive MTX doses used to treat resistant neoplasms. ■ Treatment of megaloblastic anemia due to folic acid deficiency when oral therapy not appropriate. ■ In combination with fluorouracil or fluorouracil and irinotecan to treat colorectal cancer.

Unlabeled uses:

Adjunct in the treatment of Ewing’s sarcoma, head and neck cancer, non-Hodgkin lymphomas, and trophoblastic tumors. ■ Treatment of pemetrexed toxicity.

CONTRAINDICATIONS

Pernicious anemia and other megaloblastic anemias secondary to lack of vitamin B_{12}. None when used as indicated for other specific uses.

PRECAUTIONS

Usually administered in the hospital by or under the direction of the physician specialist. ■ Permits use of massive doses of methotrexate. ■ Do not discontinue leucovorin calcium until methotrexate serum levels fall below toxic levels. ■ Much less effective in accidental overdose after a 1-hour delay. ■ Delayed MTX excretion may occur from third-space fluid accumulation (ascites, pleural effusion), renal insufficiency, or inadequate hydration. ■ All doses over 25 mg should be given IM or IV (no more than 25 mg can be absorbed orally). ■ IM or IV dosing required in presence of GI toxicity, nausea, or vomiting. ■ Benzyl alcohol associated with gasping syndrome in premature infants.

Monitor:

Monitor serum blood levels of MTX and SCr levels at least daily until level is less than 0.05 micromolar. Death can occur in 5 to 10 days if MTX remains at toxic levels longer than 48 hours. ■ Minimum fluid intake of 3 L/24 hr and alkalinization of urine to a pH of 7 or more with oral sodium bicarbonate recommended. Begin 12 hours before MTX dose and continue for 48 hours after final dose in each sequence. Does not reduce nephrotoxicity of MTX from drug or metabolite precipitation in the kidney. ■ See methotrexate or fluorouracil monograph.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established. Benefits must outweigh risks. ■ Contains benzyl alcohol; do not use in neonates or dilute with SWFI if indicated; see Dilution.

Elderly:

Response similar to that seen in younger patients; however, use caution; may have greater sensitivity to its toxic effects (e.g., greater risk for GI toxicity and severe diarrhea in combination with fluorouracil). Monitoring of renal function suggested. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

May inhibit **phenytoin, phenobarbital, and primidone;** may cause increased frequency of seizures. ■ Is used in combination with **fluorouracil;** use caution; leucovorin calcium may increase toxic as well as therapeutic effects of fluorouracil. ■ When given with **MTX,** avoid any drug that may interfere with MTX elimination or binding to serum albumin (e.g., **NSAIDs, probenecid, procarbazine, salicylates, sulfonamides**). Consider as a possible cause of toxicity. ■ High doses of leucovorin may reduce the effectiveness of intrathecally administered **methotrexate.** ■ Leucovorin may enhance the toxic effects of **capecitabine**; monitor closely. ■ Concurrent use with **sulfamethoxazole and trimethoprim** may cause treatment failure and increased morbidity in HIV patients being treated for *Pneumocystis jiroveci* pneumonia.

SIDE EFFECTS

Allergic reactions including anaphylaxis have occurred rarely. Methotrexate or fluorouracil may cause many serious and dose-limiting side effects; see individual monographs.

ANTIDOTE

Keep physician informed of patient’s condition. Symptomatic treatment indicated.

LEVETIRACETAM INJECTION

(lee-ve-tye-**RA**-se-tam in-**JEK**-shun)
Keppra
Anticonvulsant
pH 5.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Serum levels similar by oral or IV route; no dose or frequency adjustment is necessary. Transfer to oral therapy as soon as practical. Administer levetiracetam at the same dose and frequency whether given by the IV or oral route. There is no clinical study experience with administration of IV levetiracetam for longer than 4 days.

All indications:

Monotherapy or adjunctive therapy:

Initiate treatment with a daily dose of 1,000 mg/day, given as twice-daily dosing (500 mg twice daily). Monitor for 2 weeks. Dose may be increased by 1,000 mg/day (500 mg twice daily) every 2 weeks to a maximum recommended daily dose of 3,000 mg (1,500 mg twice daily).

Partial-onset seizures in adults 16 years of age and older:

There is no evidence that doses *greater* than 3,000 mg/day offer additional benefit.

Myoclonic seizures in adults and adolescents 12 years of age and older with juvenile myoclonic epilepsy and primary generalized tonic-clonic seizures in adults 16 years of age and older:

The effectiveness of doses *lower* than 3,000 mg/day has not been adequately studied.

PEDIATRIC DOSE

Partial-onset seizures:

1 month to less than 6 months of age:

Initiate treatment with a daily dose of 14 mg/kg in 2 divided doses (7 mg/kg twice daily). Increase the daily dose every 2 weeks in increments of 14 mg/kg to the recommended daily dose of 42 mg/kg (21 mg/kg twice daily). In the clinical trial, the mean daily dose was 35 mg/kg in this age-group.

6 months to less than 4 years of age:

Initiate treatment with a daily dose of 20 mg/kg in 2 divided doses (10 mg/kg twice daily). Increase the daily dose every 2 weeks in increments of 20 mg/kg to the recommended daily dose of 50 mg/kg (25 mg/kg twice daily). If the patient cannot tolerate a daily dose of 50 mg/kg, the daily dose may be reduced. In the clinical trial, the mean daily dose was 47 mg/kg in this age-group.

4 years to less than 16 years of age:

Initiate treatment with a daily dose of 20 mg/kg in 2 divided doses (10 mg/kg twice daily). Increase the daily dose every 2 weeks in increments of 20 mg/kg to the recommended daily dose of 60 mg/kg (30 mg/kg twice daily). If the patient cannot tolerate a daily dose of 60 mg/kg, the daily dose may be reduced. In the clinical trial, the mean daily dose was 44 mg/kg in this age-group. The maximum daily dose was 3,000 mg.

Myoclonic seizures in adolescents 12 years of age and older with juvenile myoclonic epilepsy:

See Usual Dose.

Primary generalized tonic-clonic seizures:

6 years to less than 16 years of age:

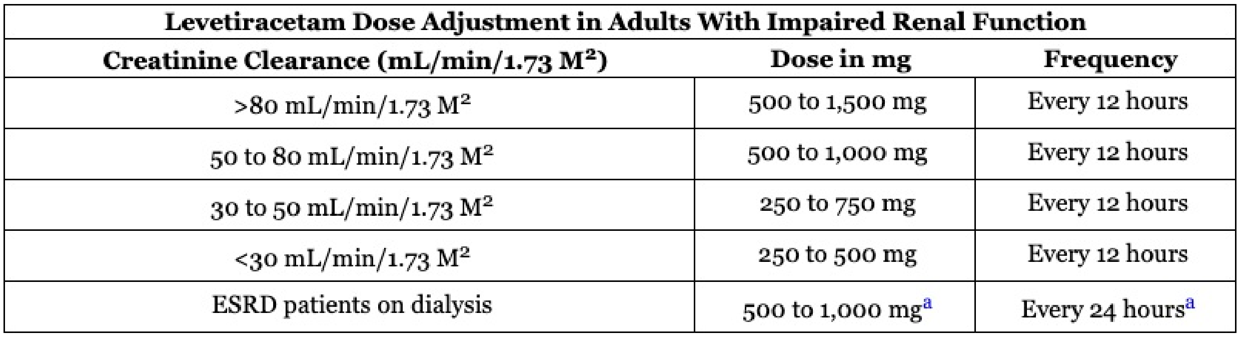
Initiate treatment with a daily dose of 20 mg/kg in 2 divided doses (10 mg/kg twice daily). Increase the daily dose every 2 weeks in increments of 20 mg/kg (10 mg/kg twice daily) to the recommended daily dose of 60 mg/kg (30 mg/kg twice daily). The effectiveness of doses lower than 60 mg/kg/day has not been adequately studied.

DOSE ADJUSTMENTS

No dose adjustment is required for gender, race, or impaired hepatic function. ■ Dose adjustment may be required in the elderly based on impaired renal function. ■ Information is unavailable for dosage adjustments in pediatric patients with renal impairment. ■ Dose adjustment for adults with impaired renal function is calculated based on CrCl adjusted for body surface area using the following formula:

$$\text{CrCl (mL/min/1.73 M}^2\text{)} = [\text{CrCl (mL/min)} \div \text{BSA (M}^2\text{)}] \times 1.73$$

Adjust dose according to the following chart.



Levetiracetam Dose Adjustment in Adults With Impaired Renal Function

Creatinine Clearance (mL/min/1.73 M^2)	Dose in mg	Frequency
>80 mL/min/1.73 M^2	500 to 1,500 mg	Every 12 hours
50 to 80 mL/min/1.73 M^2	500 to 1,000 mg	Every 12 hours
30 to 50 mL/min/1.73 M^2	250 to 750 mg	Every 12 hours
<30 mL/min/1.73 M^2	250 to 500 mg	Every 12 hours
ESRD patients on dialysis	500 to 1,000 mg[a]	Every 24 hours[a]

[a] Administration of a 250- to 500-mg supplemental dose following dialysis is recommended.

DILUTION

Adults:

Each vial contains 500 mg/5 mL (100 mg/mL). A single dose (500, 1,000, or 1,500 mg [1, 2, or 3 vials]) must be diluted in 100 mL of NS, LR, or D5W for infusion. Doses of 500, 1,000, or 1,500 mg are available prediluted in 100 mL of NS.

Pediatric patients:

A smaller volume of infusion solution may be required due to limitations around the total daily fluid intake of the patient. The amount of diluent should be calculated such that the final concentration of the levetiracetam solution does not exceed 15 mg/mL. For example, a 1-year-old, 10-kg child beginning therapy for treatment of partial-onset seizures would initiate therapy at 20 mg/kg/day = 200 mg/day = 100 mg twice daily. 100 mg (1 mL) mixed in 24 mL of **compatible** solution will provide a final concentration of 4 mg/mL. In a fluid-restricted patient, the solution volume could be decreased to as low as 5.7 mL [100 mg ÷ (1 mL from drug + 5.7 mL of solution) = 14.9 mg/mL].

Filters:

Specific information not available.

Storage:

Store at CRT. Diluted solution should not be stored for more than 4 hours at CRT in polyvinyl chloride (PVC) bags. Discard any unused portion of vial.

COMPATIBILITY

Manufacturer lists solutions NS, LR, and D5W and other antiepileptic drugs lorazepam (Ativan), diazepam (Valium), and valproate sodium (Depacon) as **compatible** for 4 hours stored in polyvinyl chloride (PVC) bags at CRT.

RATE OF ADMINISTRATION

A single dose properly diluted as an infusion over 15 minutes.

ACTIONS

An antiepileptic (anticonvulsant) drug. The precise mechanism of action is unknown. In animal studies it inhibited burst firing without affecting normal neuronal excitability, which suggests that it may selectively prevent hypersynchronization of epileptiform burst firing and propagation of seizure activity in human complex partial seizures. Less than 10% bound to plasma proteins. Not extensively metabolized in humans and not liver (cytochrome P_{450}) dependent. Undergoes enzymatic hydrolysis. Half-life is 6 to 8 hours. Primarily excreted in urine as unchanged drug and metabolites. Crossed the placental barrier in animal studies. Secreted in breast milk.

INDICATIONS AND USES

Treatment of partial-onset seizures in adults and pediatric patients 1 month of age and older. ■ Adjunctive therapy in the treatment of myoclonic seizures in adults and adolescents 12 years of age and older with juvenile myoclonic epilepsy (JME). ■ Adjunctive therapy in the treatment of primary generalized tonic-clonic seizures in adults and pediatric patients 6 years of age and older with idiopathic generalized epilepsy.

Limitations of Use:

For IV use only as an alternative for patients when oral administration is temporarily not feasible.

CONTRAINDICATIONS

Known hypersensitivity to levetiracetam.

PRECAUTIONS

For IV use only. ■ Associated with CNS side effects (e.g., somnolence and fatigue, coordination difficulties [abnormal gait, ataxia, incoordination], behavioral abnormalities [e.g., aggression, agitation, anger, anxiety, apathy, depersonalization, depression, emotional lability, hostility, hyperkinesias, irritability, nervousness, neurosis, personality disorders], and psychotic symptoms [paranoia, psychosis, suicidal tendencies]). Somnolence and fatigue and coordination difficulties occurred most frequently within the first 4 weeks of treatment and resolved or improved with dose reduction or discontinuation of levetiracetam. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. Some behavioral changes resolved without intervention. Others required dose reduction or discontinuation of levetiracetam. ■ Serious dermatologic reactions, including Stevens-Johnson syndrome and toxic epidermal necrolysis, have been reported. Median time to onset is 14 to 17 days, but development up to 4 months after initiation of therapy has been reported. ■ Hypersensitivity reactions, including angioedema and anaphylaxis, have been reported. ■ To minimize the potential of increased seizure frequency, withdraw antiepileptic drugs (including levetiracetam) gradually. If withdrawal is needed because of a serious adverse reaction, rapid discontinuation can be considered. ■ Hematologic abnormalities have been reported. ■ Increase in diastolic BP has been reported in patients 1 month to under 4 years of age who are receiving the oral formulation of levetiracetam. This side effect was not observed in older pediatric patients or adults.

Monitor:

Baseline CBC and CrCl indicated; monitor as needed. Decreases in WBC, neutrophils, RBC, hemoglobin, and hematocrit have been reported, but a change or discontinuation of therapy was not required. Increases in eosinophil counts and cases of agranulocytosis, pancytopenia, and thrombocytopenia have also been reported. A CBC is recommended in patients experiencing significant coagulation disorders, fever, recurrent infections, or significant weakness. ■ Monitor for psychiatric S/S. ■ Monitor for somnolence and fatigue. ■ Monitor for seizure activity. ■ Observe patient closely for signs of CNS side effects; see Precautions. ■ Monitor vital signs. Pediatric patients 1 month to under 4 years of age should be monitored for a possible increase in diastolic BP. ■ Monitor for serious dermatologic reactions. ■ Monitor for S/S of a hypersensitivity reaction, which can occur with the first dose or any time throughout treatment.

Patient Education:

May cause dizziness, coordination difficulties, and somnolence; use caution when performing tasks that require alertness or coordination (e.g., operating machinery, driving). ■ Inform your health care professional if you are pregnant or breast-feeding. ■ May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry. ■ May cause serious dermatologic reactions; promptly report development of a rash. ■ Discontinue levetiracetam and seek medical care if S/S of a hypersensitivity reaction (e.g., facial edema, hives, hypotension, respiratory distress) develop.

Maternal/Child:

Although available studies cannot definitively establish the absence of risk, data from the published literature and pregnancy registries have not established an association between levetiracetam use during pregnancy and major birth defects or miscarriage. Animal studies demonstrated evidence of developmental toxicity, including teratogenic effects. ■ Physiologic changes during pregnancy may decrease levetiracetam concentration. Monitor carefully during pregnancy. Extend monitoring to postpartum period if dose adjustments were required during the pregnancy. ■ Effects during labor and delivery unknown. ■ There are no data on the effects of levetiracetam on the breast-fed infant or the effects on milk production. ■ Safety and effectiveness for use in certain pediatric populations have been established; see Indications. ■ Pharmacokinetic analysis showed that body weight was significantly correlated to the clearance of levetiracetam in pediatric patients; clearance increased with an increase in body weight.

Elderly:

Safety similar to that seen in younger adults; however, total body clearance is decreased and half-life is increased. ■ Reduced doses may be indicated; see Dose Adjustments. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Manufacturer states that levetiracetam “is unlikely to produce, or be subject to, pharmacokinetic interactions.” ■ An increase in the clearance of levetiracetam was seen in pediatric patients when it was coadministered with **enzyme-inducing AEDs** (e.g., carbamazepine, phenytoin). Dose adjustment was not recommended. ■ **Probenecid** decreases renal clearance and increases serum concentrations of one of the metabolites of levetiracetam. ■ Levetiracetam may increase serum concentration of **methotrexate**, resulting in serious adverse events, including acute kidney failure. Careful monitoring of serum levels of methotrexate is recommended.

SIDE EFFECTS

Adults:

Asthenia, dizziness, infection, and somnolence occurred most frequently during the first 4 weeks of treatment.

Pediatric patients:

Aggression, decreased appetite, fatigue, irritability, and nasal congestion were most commonly reported.

Patients of all ages:

Other side effects reported and presenting anywhere from 1 to 4 weeks included amnesia; anorexia; anxiety; ataxia; cough; decreased RBC, WBC, Hct, and Hgb; depersonalization; depression; diarrhea; diplopia; emotional lability; headache; hostility; influenza; insomnia; irritability; mood swings; neck pain; nervousness; pain; paresthesia; pharyngitis; rhinitis; seizures; sinusitis; and vertigo.

Post-Marketing:

Abnormal liver function tests, acute kidney injury, agranulocytosis, anaphylaxis, angioedema, choreoathetosis, drug rash with eosinophilia and systemic symptoms (DRESS), dyskinesia, erythema multiforme, hepatic failure, hepatitis, hyponatremia, leukopenia, muscle weakness, neutropenia, pancreatitis, pancytopenia (with bone marrow suppression), panic attack, Stevens-Johnson syndrome (SJS), suicidal behavior, thrombocytopenia, toxic epidermal necrolysis (TEN), and weight loss. Alopecia has been reported; recovery occurred in the majority of cases if levetiracetam was discontinued.

Overdose:

Aggression, agitation, coma, depressed level of consciousness, drowsiness, respiratory depression, and somnolence.

ANTIDOTE

Keep physician informed of all side effects. Some may not require intervention, and others may improve with a reduced dose or discontinuation of levetiracetam; see Precautions and Side Effects. Discontinue at first sign of rash, unless the rash is clearly not drug related. If S/S suggest SJS/TEN, use of this drug should not be resumed and alternative therapy should be considered. Discontinue if a hypersensitivity reaction occurs and treat as indicated. If a clear alternative etiology for the reaction cannot be established, levetiracetam should be discontinued permanently. Support patient as required in treatment of overdose. No specific antidote in overdose; however, hemodialysis will remove approximately 50% of a dose in 4 hours.

LEVOCARNITINE

(**LEE**-voh-**KAR**-nih-teen)
Carnitor
Nutritional supplement
pH 6 to 6.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Metabolic disorders in adults and pediatric patients:

50 mg/kg/24 hr in equally divided doses every 3 to 4 hours is preferred (i.e., 6.25 mg/kg every 3 hours or 8.3 mg/kg every 4 hours). Intervals between administration must never exceed 6 hours. Repeat daily and adjust dose as indicated by clinical response or as therapy may require. In ***severe metabolic crisis*** an initial loading dose of 50 mg/kg may be given followed by an equivalent dose (50 mg/kg) in equally divided doses every 3 to 4 hours over the following 24 hours. Then give 50 mg/kg/day and adjust dose as indicated. Doses up to 300 mg/kg/day have been given.

Carnitine deficiency in adult and pediatric dialysis patients:

10 to 20 mg/kg of dry body weight into the venous return line after each dialysis session. Initiate therapy if trough (pre-dialysis) plasma levocarnitine concentrations are below a normal of 40 to 50 mcM/L. Do not use oral levocarnitine in patients with end-stage renal disease (ESRD); see Precautions.

DOSE ADJUSTMENTS

In dialysis patients, adjust dose based on trough (pre-dialysis) plasma levocarnitine concentrations. Reductions to 5 mg/kg may be indicated as early as the third or fourth week of therapy. ■ See Precautions.

DILUTION

May be given by IV injection or added to NS or LR for infusion.

Storage:

Store vials at CRT. Discard any unused portion; contains no preservative. Infusion solutions ranging from 0.5 to 8 mg/mL are stable for 24 hours at RT in PVC plastic bags.

COMPATIBILITY

Specific information not available; consult pharmacist. Manufacturer lists **compatibility** with NS or LR in PVC infusion bags.

RATE OF ADMINISTRATION

IV injection:

A single dose equally distributed over 2 to 3 minutes.

Infusion:

Give at rate ordered for primary infusion. Do not exceed direct IV rate.

ACTIONS

A naturally occurring substance required in energy metabolism. Facilitates entry of long-chain fatty acids into cellular mitochondria, providing substrate for oxidation and subsequent energy production. Fatty acids are used as an energy source in all tissues except the brain. Primary systemic carnitine deficiency is characterized by low concentrations of carnitine in plasma, RBCs and/or tissues. Secondary carnitine deficiency may be caused by inborn errors in metabolism or by iatrogenic factors such as hemodialysis. Carnitine deficiency is associated with accumulation of excess acyl CoA esters and disruption of intermediary metabolism. The subsequent hydrolysis of the acyl CoA compound to its free acid results in acidosis, which can be life threatening. Levocarnitine promotes the excretion of excess organic or fatty acids in patients with defects in fatty acid metabolism and/or specific organic acidopathies that bioaccumulate acyl CoA esters. Clears toxic organic acids by forming acylcarnitine, which is excreted primarily in the urine. Following IV administration, 76% of the levocarnitine dose is excreted in the urine during a 0- to 24-hour interval. Half-life is 17.4 hours.

INDICATIONS AND USES

Acute and chronic treatment of adult and pediatric patients with an inborn error of metabolism that results in secondary carnitine deficiency (e.g., glutaric aciduria II, methyl malonic aciduria, propionic acidemia, medium chain fatty acyl CoA dehydrogenase deficiency). ■ Prevention and treatment of carnitine deficiency in end-stage renal disease patients undergoing dialysis.

Unlabeled uses:

Treatment of valproate toxicity.

CONTRAINDICATIONS

None known at this time when used as directed for specific indications.

PRECAUTIONS

Oral dose form used to treat primary carnitine deficiency and when feasible in secondary deficiency. ■ Serious hypersensitivity reactions, including anaphylaxis, laryngeal edema, and bronchospasm have occurred (mostly in patients with end-stage renal disease who are undergoing dialysis). ■ Safety and effectiveness of oral levocarnitine has not been evaluated in patients with renal dysfunction. Chronic administration in patients with severe renal impairment may lead to accumulation of potentially toxic metabolites that are normally excreted in urine. Use only the IV formulation in patients with ESRD, patients receiving dialysis, or patients with severe impaired renal function. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline plasma carnitine levels before treatment and monitor weekly and then monthly based on response (normal range of free carnitine levels is 35 to 60 micromoles/L). ■ Monitor blood chemistries, vital signs, and overall clinical condition before treatment, as indicated during acute phase and weekly to monthly thereafter. ■ Monitor for S/S of a hypersensitivity reaction (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). ■ End stage renal disease (ESRD) patients on maintenance hemodialysis may have low plasma carnitine concentrations and an increased ratio of acylcarnitine/carnitine because of reduced intake of meat and dairy products, reduced renal synthesis and dialytic losses. Certain clinical conditions common in hemodialysis patients such as malaise, muscle weakness, cardiomyopathy, and cardiac arrhythmias may be related to abnormal carnitine metabolism.

Patient Education:

Stress importance of follow-up evaluation and treatment.

Maternal/Child:

No adequate studies; use only if clearly needed. ■ Has not been studied in breast-feeding mothers. Consider risks of excess carnitine intake to the nursing infant against benefit of levocarnitine supplementation to the mother. Consideration may be given to discontinuation of breast-feeding or of levocarnitine treatment.

DRUG/LAB INTERACTIONS

Increases in INR have been reported in patients receiving levocarnitine and warfarin. Monitor INR in patients undergoing warfarin therapy after the initiation of treatment with levocarnitine therapy or after any dose adjustment.

SIDE EFFECTS

Transient nausea and vomiting have been observed. Less frequently reported adverse reactions are body odor, gastritis, and nausea. The prescribing information lists several other possible adverse events without regard to causality.

Post-marketing:

Hypersensitivity reactions, including anaphylaxis, bronchospasm, and laryngeal edema. Seizures have been reported with or without a history of seizures. An increased incidence of seizures has been reported in patients with a history of seizures.

ANTIDOTE

Keep physician informed. If clinically appropriate, dose reduction may decrease or eliminate body odor and GI symptoms. Discontinue levocarnitine if a severe hypersensitivity reaction occurs and initiate appropriate medical treatment. Consider risks and benefits of re-administering levocarnitine to individual patients following a severe reaction. No reports of toxicity, but treatment would be supportive. Removed by dialysis.

LEVOFLOXACIN BBW

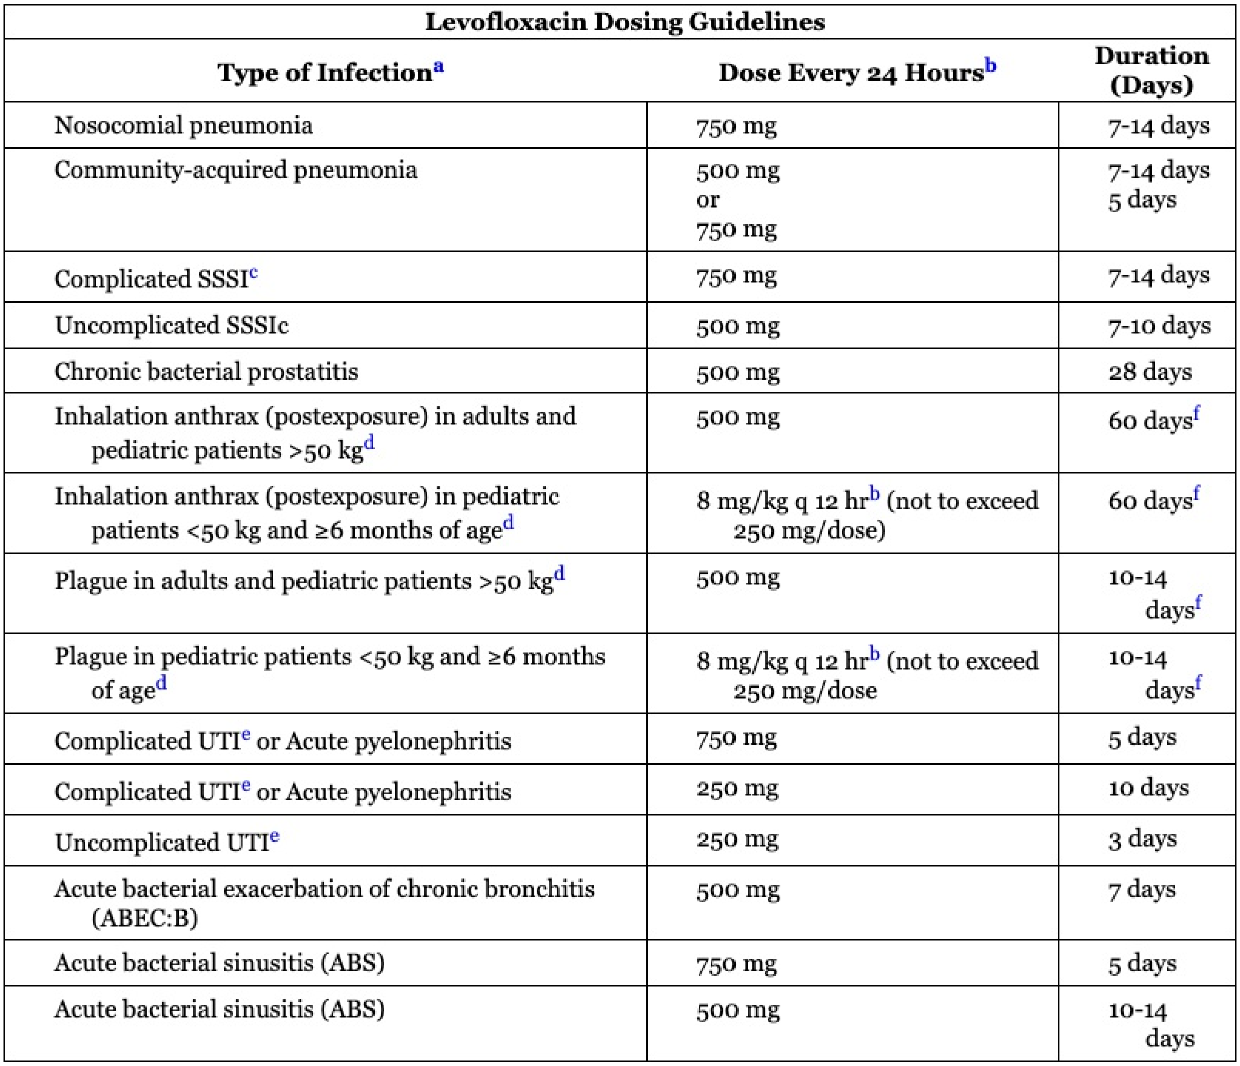
(**lee**-voh-**FLOX**-ah-sin)
Levaquin
Antibacterial (fluoroquinolone)
pH 3.8 to 5.8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

250 to 750 mg once every 24 hours. Dose and duration of treatment are based on degree of infection and specific diagnosis. CrCl equal to or greater than 50 mL/min is required. Dose and serum levels similar by oral or IV route. Transfer to oral dose as soon as practical.



Levofloxacin Dosing Guidelines

Type of Infection[a]	Dose Every 24 Hours[b]	Duration (Days)
Nosocomial pneumonia	750 mg	7-14 days
Community-acquired pneumonia	500 mg or 750 mg	7-14 days 5 days
Complicated SSSI[c]	750 mg	7-14 days
Uncomplicated SSSIc	500 mg	7-10 days
Chronic bacterial prostatitis	500 mg	28 days
Inhalation anthrax (postexposure) in adults and pediatric patients >50 kg[d]	500 mg	60 days[f]
Inhalation anthrax (postexposure) in pediatric patients <50 kg and ≥6 months of age[d]	8 mg/kg q 12 hr[b] (not to exceed 250 mg/dose)	60 days[f]
Plague in adults and pediatric patients >50 kg[d]	500 mg	10-14 days[f]
Plague in pediatric patients <50 kg and ≥6 months of age[d]	8 mg/kg q 12 hr[b] (not to exceed 250 mg/dose	10-14 days[f]
Complicated UTI[e] or Acute pyelonephritis	750 mg	5 days
Complicated UTI[e] or Acute pyelonephritis	250 mg	10 days
Uncomplicated UTI[e]	250 mg	3 days
Acute bacterial exacerbation of chronic bronchitis (ABEC:B)	500 mg	7 days
Acute bacterial sinusitis (ABS)	750 mg	5 days
Acute bacterial sinusitis (ABS)	500 mg	10-14 days

[a] Due to the designated pathogens (see Indications and Usage in manufacturer's prescribing information).

[b] Frequency is every 12 hours (not 24 hours) for treatment of inhalation anthrax and plague in pediatric patients less than 50 kg and age 6 months or more.

[c] Skin and skin structure infections.

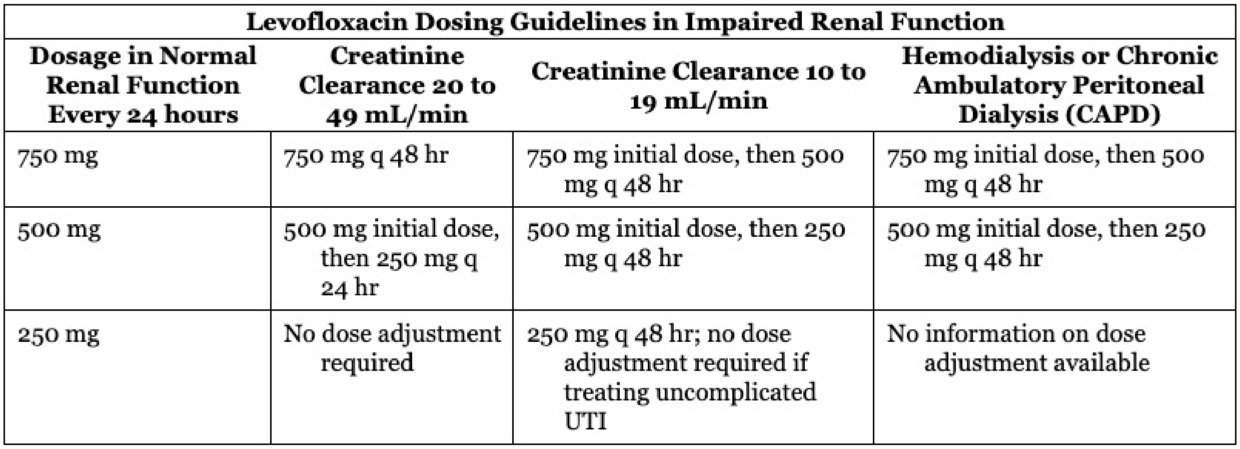
[d] Begin drug administration as soon as possible after suspected or confirmed exposure to aerosolized Bacillus anthracis or to Yersinia pestis.

[e] Urinary tract infections.

[f] See Precautions and Maternal/Child.

DOSE ADJUSTMENTS

No dose adjustment is required specifically for age, gender, race, or in impaired hepatic function. ■ Clearance is reduced and half-life is prolonged in patients with a CrCl less than 50 mL/min. See the following chart for dosing guidelines. See Important IV Therapy Facts on p. xix for formula to convert SCr to CrCl. ■ Supplemental doses are not required after hemodialysis or peritoneal dialysis.



Levofloxacin Dosing Guidelines in Impaired Renal Function

Dosage in Normal Renal Function Every 24 hours	Creatinine Clearance 20 to 49 mL/min	Creatinine Clearance 10 to 19 mL/min	Hemodialysis or Chronic Ambulatory Peritoneal Dialysis (CAPD)
750 mg	750 mg q 48 hr	750 mg initial dose, then 500 mg q 48 hr	750 mg initial dose, then 500 mg q 48 hr
500 mg	500 mg initial dose, then 250 mg q 24 hr	500 mg initial dose, then 250 mg q 48 hr	500 mg initial dose, then 250 mg q 48 hr
250 mg	No dose adjustment required	250 mg q 48 hr; no dose adjustment required if treating uncomplicated UTI	No information on dose adjustment available

DILUTION

Available in single-use vials and as prediluted, ready-to-use infusions.

Single-use vials:

Withdraw desired dose from single-use vial (10 mL for 250 mg, 20 mL for 500 mg, 30 mL for 750 mg). Each 10 mL (250 mg) must be further diluted with a minimum of 40 mL NS, D5W, D5NS, D5LR, or D5/½NS. Desired concentration is 5 mg/mL. No preservatives; enter vial only once. When 500-mg (20-mL) vial is used to prepare two 250-mg doses, withdraw entire contents of vial at once using a single-entry procedure. Prepare and store second dose for subsequent use.

Premix flexible containers:

No further dilution necessary. Available as 250 mg in 50 mL, 500 mg in 100 mL, or 750 mg in 150 mL D5W. Instructions for access to and use of premix flexible containers are on its storage carton. Do not use flexible containers in series connections.

Filters:

Not required; however, contents of both vials and premixed solutions were filtered during manufacturing with polyvinyl mixed ester cellulose filters. Size not specified by manufacturer. No significant loss of potency expected.

Storage:

Store vials at CRT; protect from light. Store premix at or below 25° C (77° F); protect from freezing, light, and excessive heat. Premixed product may also be stored in the refrigerator. Brief exposure up to 40° C (104° F) does not adversely affect the product. Both are stable to expiration date. Solutions diluted from vials are stable at or below 25° C (77° F) for 3 days and for up to 14 days if refrigerated. May be frozen for up to 6 months. Do not force thaw (e.g., microwave or water bath) and do not refreeze. Discard any unused portion of premixed solutions and/or opened vials.

COMPATIBILITY

Manufacturer states, “Limited **compatibility** information available; other intravenous substances, additives, or other medications should not be added to levofloxacin or infused simultaneously through the same intravenous line.” Never administer in the same IV or through the same tubing with any solution containing multivalent cations (e.g., calcium, magnesium). Flush line with a **compatible** solution before and after administration of levofloxacin and/or any other drug through the same IV line.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 250- or 500-mg dose must be given over 60 minutes as an infusion. A 750-mg dose must be given over 90 minutes as an infusion. Too-rapid administration may cause hypotension. May be given through a Y-tube or three-way stopcock of infusion set. Temporarily discontinue other solutions infusing at the same site and flush tubing with **compatible** solutions before and after levofloxacin.

ACTIONS

A synthetic, broad-spectrum, fluoroquinolone antibacterial agent. Bactericidal to aerobic gram-negative and gram-positive organisms through interference with enzymes (type II topoisomerases) needed for bacterial DNA replication, transcription, repair, and recombination. May be active against bacteria resistant to aminoglycosides, beta-lactam antibiotics, and macrolides. Onset of action is prompt, and serum levels are dose related. Mean terminal half-life is 6 to 8 hours. Steady state is achieved within 48 hours. Widely distributed into body tissues, including blister fluid and lung tissues. Moderately bound to serum protein (24% to 38%). Metabolism is minimal; primarily excreted as unchanged drug in urine. Very small amounts found in bile and feces. May cross placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Treatment of adults with mild, moderate, and severe infections caused by susceptible strains of designated microorganisms in conditions listed in this section. ■ Treatment of nosocomial pneumonia. For cases in which *Pseudomonas aeruginosa* is a documented or presumptive organism, combination therapy with an anti-pseudomonal beta-lactam is recommended. ■ Treatment of community-acquired pneumonia due to many organisms, including *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP]). MDRSP strains are resistant to two or more of the following antibiotics: penicillin, second-generation cephalosporins (e.g., cefuroxime), macrolides, tetracyclines, and sulfamethoxazole/trimethoprim. ■ Treatment of complicated skin and skin structure infections and mild to moderate uncomplicated skin and skin structure infections. ■ Treatment of complicated urinary tract infections and acute pyelonephritis (including cases with concurrent bacteremia). ■ Treatment of uncomplicated urinary tract infections. Because fluoroquinolones, including levofloxacin, have been associated with serious adverse reactions and because for some patients uncomplicated urinary tract infection is self-limiting, reserve levofloxacin for treatment of uncomplicated urinary tract infections in patients who have no alternative treatment options. ■ Treatment of acute bacterial exacerbation of chronic bronchitis (ABECB) and acute bacterial sinusitis (ABS). Because fluoroquinolones, including levofloxacin, have been associated with serious adverse reactions and because for some patients ABECB and ABS are self-limiting, reserve levofloxacin for treatment in patients who have no alternative treatment options. ■ To reduce the incidence or progression of inhalational anthrax following exposure to *Bacillus anthracis* in adults and pediatric patients. Begin administration as soon as possible after suspected or confirmed exposure. Transfer to oral therapy when practical. ■ Treatment of plague, including pneumonic and septicemic plague, due to *Yersinia pestis,* as well as prophylaxis for plague in adults and pediatric patients 6 months of age and older. ■ Treatment of chronic bacterial prostatitis (usually oral therapy).

CONTRAINDICATIONS

History of hypersensitivity to levofloxacin, its components, or any other quinolone antimicrobial agents (e.g., ciprofloxacin, norfloxacin).

PRECAUTIONS

For IV use only. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, levofloxacin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Culture and sensitivity studies indicated to determine susceptibility of the causative organism to levofloxacin. ■ *Pseudomonas aeruginosa* may develop resistance during treatment. Ongoing culture and sensitivity studies indicated. ■ The emergence of bacterial resistance to fluoroquinolones and the occurrence of crossresistance with other fluoroquinolones have been observed and are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ Cross-resistance may occur with other fluoroquinolones, but some microorganisms resistant to other fluoroquinolones may be susceptible to levofloxacin. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ Fluoroquinolones, including levofloxacin, have been associated with disabling and potentially irreversible serious adverse reactions that have occurred together in the same patient. Commonly seen adverse reactions include tendinitis and tendon rupture, arthralgia, myalgia, peripheral neuropathy, CNS effects (e.g., anxiety, confusion, depression, hallucinations, insomnia, severe headaches), and hypoglycemia or hyperglycemia. Due to the potential for side effects, the FDA suggests not using levofloxacin unless there are no other alternatives. These reactions can occur within hours to weeks after starting levofloxacin and have been seen in patients of any age and in patients without any pre-existing risk factors. Discontinue levofloxacin immediately and avoid the use of fluoroquinolones, including levofloxacin, in patients who experience any of these serious adverse reactions. ■ Fluoroquinolones, including levofloxacin, have been associated with an increased risk of seizures (convulsions), increased intracranial pressure (pseudotumor cerebri), tremors, and light-headedness. May trigger seizures or lower the seizure threshold. Use caution in patients with epilepsy or known or suspected CNS disorders that may predispose patients to seizures or lower the seizure threshold (e.g., severe cerebral arteriosclerosis, previous history of convulsions, reduced cerebral blood flow, altered brain structure, or stroke) or in the presence of other risk factors that may predispose patients to seizures (e.g., drugs that may lower the seizure threshold, renal dysfunction). ■ Fluoroquinolones, including levofloxacin, have been associated with an increased risk of psychiatric adverse reactions, including toxic psychosis; psychotic reactions progressing to suicidal ideations/thoughts, hallucinations, or paranoia; depression or self-injurious behavior such as attempted or completed suicide; anxiety, agitation, restlessness, or nervousness; confusion, delirium, disorientation, or disturbances in attention; insomnia or nightmares; and memory impairment. These reactions may occur after the first dose. ■ Use caution in patients with impaired renal function; see Dose Adjustments. ■ Severe, sometimes fatal hepatotoxicity has been reported. Symptoms appeared within 6 to 14 days of initiating therapy, and most cases were not associated with hypersensitivity. The majority of fatal hepatotoxicity reports occurred in patients 65 years of age or older; see Patient Education and Antidote. ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients of all ages receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Tendon rupture or tendinitis may occur during or up to months after fluoroquinolone therapy and may occur bilaterally. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. Avoid levofloxacin in patients who have a history of tendon disorders or have experienced tendinitis or tendon rupture. Discontinue levofloxacin immediately if patient experiences pain, swelling, inflammation, or rupture of a tendon. ■ Prolongation of the QT interval on ECG and infrequent cases of arrhythmia (including torsades de pointes) have been reported. The risk of arrhythmia may be reduced by avoiding the use of levofloxacin in patients with known prolongation of the QT interval, uncorrected electrolyte imbalances (e.g., hypokalemia, hypomagnesemia), significant bradycardia, cardiomyopathy, or concurrent treatment with Class Ia antiarrhythmic agents (e.g., quinidine, procainamide) or Class III antiarrhythmic agents (e.g., amiodarone, sotalol) and any other drug that can prolong the QT interval; avoid coadministration; see Drug/Lab Interactions. ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Serious adverse events, including a requirement for ventilatory support and deaths, have been reported in these patients. Avoid use in patients with a known history of myasthenia gravis. ■ Fluoroquinolones, including levofloxacin, have been associated with an increased risk of peripheral neuropathy. Cases of sensory or sensorimotor axonal polyneuropathy resulting in paresthesias, hypoesthesias, dysesthesias (impairment of sensitivity or touch), or weakness have been reported. Symptoms may occur soon after initiation of therapy and may be irreversible. Avoid levofloxacin in patients who have previously experienced peripheral neuropathy. ■ Serious and occasionally fatal hypersensitivity and/or anaphylactic reactions have been reported. Often occur after the first dose. ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including levofloxacin; usually occur after multiple doses. Manifestations may include allergic pneumonitis, arthralgia, myalgia, renal or hepatic impairment/failure, hematologic toxicity, dermatologic toxicity, serum sickness, and vasculitis; see Side Effects, Post-Marketing. Immediately discontinue levofloxacin at the first appearance of a skin rash, jaundice, or other signs of hepatotoxicity or hypersensitivity. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with levofloxacin. ■ Epidemiologic studies report an increased rate of aortic aneurysm and dissection within 2 months after use of fluoroquinolones, particularly in elderly patients. In patients with a known aortic aneurysm or in patients who are at greater risk for aortic aneurysms, levofloxacin use should be limited to cases in which no alternative antibacterial treatments are available. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see Patient Education. ■ Fluoroquinolones, including levofloxacin, have been associated with disturbances of blood glucose, including symptomatic hyperglycemia and hypoglycemia, usually in patients with diabetes who are receiving concomitant treatment with an oral hypoglycemic agent (e.g., glyburide) or with insulin. In these patients careful monitoring of blood glucose is recommended. Severe cases of hypoglycemia resulting in coma or death have been reported. ■ Not tested in humans for postexposure prevention of inhalation anthrax; however, plasma concentrations are considered to be in a range to produce effective results. ■ Safety for use in adults beyond 28 days or in pediatric patients beyond 14 days not studied; use only for prescribed indication; benefits must outweigh risks. An increased incidence of musculoskeletal adverse events has been observed in pediatric patients.

Monitor:

Obtain baseline CBC with differential, CrCl, and blood glucose. Periodic monitoring of organ systems, including hematopoietic, hepatic, and renal, is recommended. ■ Monitor for S/S of a hypersensitivity reaction (e.g., airway obstruction, angioedema, cardiovascular collapse, dyspnea, hypotension/shock, itching, loss of consciousness, seizure, tingling, urticaria, and other serious skin reactions). May cause anaphylaxis with the first or succeeding doses, even in patients without known hypersensitivity. Emergency equipment must always be available; see Precautions. ■ Monitor for S/S of peripheral neuropathy. Discontinue levofloxacin at the first symptoms of neuropathy (e.g., pain, burning, tingling, numbness and/or weakness) or if patient is found to have deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ ECG monitoring for QT prolongation may be indicated in select patients. ■ Monitor for CNS adverse effects, including altered mental status, seizures, and changes in mood or behavior. ■ Monitor for S/S of tendinitis or tendon rupture. ■ Maintain adequate hydration to prevent concentrated urine throughout treatment. Crystalluria and cylindruria have been reported with quinolones. ■ Monitor infusion site for inflammation and/or extravasation. ■ Monitor blood glucose, especially in patients with diabetes. ■ See Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

A patient medication guide is available from the manufacturer. ■ Discontinue levofloxacin and promptly report the development of any severe adverse reaction. ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Inform physician of any history of myasthenia gravis. ■ Patients with a history of myasthenia gravis should avoid the use of levofloxacin. ■ Drink fluids liberally. ■ Promptly report skin rash or any other hypersensitivity reaction. ■ Promptly report pain, burning, tingling, numbness and/or weakness in extremities. Nerve damage can be permanent. ■ Photosensitivity has been reported. Avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Promptly report development of any CNS side effects (e.g., convulsions, dizziness, light-headedness, change in mood or behavior). ■ Inform physician of any history of seizures. ■ Request assistance with ambulation; may cause dizziness and light-headedness. Use caution in tasks that require alertness. ■ Effects of caffeine, theophylline preparations, and/or warfarin (Coumadin) may be increased; notify your physician if you take any of these agents. If diabetic and on medication, monitor your blood glucose carefully. If a hypoglycemia reaction occurs, discontinue levofloxacin and consult physician. ■ Promptly report S/S of liver injury (e.g., dark-colored urine, fever, itching, jaundice [yellowing of skin or whites of eyes], light-colored bowel movements, loss of appetite, nausea, right upper quadrant tenderness, tiredness, vomiting, weakness). ■ Promptly report tendon pain or inflammation, weakness, or the inability to use a joint; rest and refrain from exercise. ■ Before initiating therapy, parents should inform their child's physician if their child has a history of joint-related problems, and they should notify their child's physician of any tendon or joint-related problems that occur during or after therapy. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Seek emergency medical care if sudden chest, stomach, or back pain is experienced. ■ See Precautions, Monitor, Drug/Lab Interactions, and Antidote.

Maternal/Child:

Safety for use in pregnancy not established; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age not established. Indicated in pediatric patients 6 months of age or older only for prevention of inhalation anthrax (postexposure) and prevention and treatment of plague. The risk-benefit assessment indicates that administration of levofloxacin to pediatric patients for these indications is appropriate. Safety for use in pediatric patients under 6 months of age not established. ■ An increased incidence of musculoskeletal disorders (arthralgia, arthritis, tendinopathy, and gait abnormality) compared with controls has been observed in pediatric patients receiving levofloxacin. May erode cartilage of weight-bearing joints or cause other signs of arthropathy in infants and children.

Elderly:

Half-life may be slightly extended due to age-related renal impairment. Dose reduction required only in the elderly with a CrCl of less than 50 mL/min. ■ Safety and effectiveness similar to that in younger adults; however, they may experience an increased risk of side effects (e.g., aortic aneurysm and dissection, CNS effects, hepatotoxicity, tendinitis, tendon rupture, risk of QT prolongation). Monitoring of renal function may be useful. ■ See Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

May cause ventricular arrhythmias or torsades de pointes with **drugs that prolong the QT interval,** such as **Class Ia antiarrhythmic agents** (e.g., quinidine, procainamide), **Class III antiarrhythmic agents** (e.g., amiodarone, sotalol), **phenothiazines** (e.g., chlorpromazine), **tricyclic antidepressants** (e.g., imipramine, amitriptyline). Avoid coadministration. ■ Risk of CNS stimulation and convulsive seizures may be increased with **NSAIDs**. ■ May cause hyperglycemia and hypoglycemia with concurrent administration of **antidiabetic agents**; monitoring of blood glucose recommended. ■ Interactions with **theophylline** that occur with other quinolones have not been noted, but monitoring of theophylline levels is recommended with concomitant use. ■ May enhance effects of **warfarin**; monitoring of PT or INR is recommended with concomitant use. ■ May cause **false-positive when testing urine for opiates;** more specific testing methods may be indicated.

SIDE EFFECTS

The most common side effects are constipation, diarrhea, dizziness, headache, insomnia, and nausea. Abdominal pain, chest pain, crystalluria, cylindruria, dyspepsia, dyspnea, edema, injection site reaction, moniliasis, photosensitivity/phototoxicity (sun sensitivity), pruritus, rash, vaginitis, and vomiting have occurred. Abnormal dreaming, abnormal gait, abnormal hepatic function, abnormal renal function, acute renal failure, agitation, anemia, anorexia, anxiety, arthralgia, cardiac arrest, CDAD, confusion, convulsions, depression, epistaxis, esophagitis, gastritis, gastroenteritis, genital moniliasis, glossitis, granulocytopenia, hallucinations, hyperglycemia, hyperkalemia, hyperkinesia, hypersensitivity reactions, hypertonia, hypoglycemia, increased alkaline phosphatase, increased hepatic enzymes, myalgia, nightmares, palpitation, pancreatitis, paresthesia, phlebitis, pseudomembranous colitis, skeletal pain, sleep disorders, somnolence, stomatitis, syncope, tendinitis, thrombocytopenia, tremor, urticaria, ventricular arrhythmia, ventricular tachycardia, and vertigo have also been reported in fewer than 1% of patients.

Post-Marketing:

Abnormal EEG; hematologic abnormalities (agranulocytosis, anemia [hemolytic and aplastic], eosinophilia, leukopenia, pancytopenia, thrombocytopenia [including thrombotic thrombocytopenic purpura]); exacerbation of myasthenia gravis; eye disorders (e.g., blurred vision, diplopia, reduced visual acuity, scotoma, uveitis); hepatic failure, including fatal cases; fever; hepatitis; hypersensitivity reactions (sometimes fatal, including angioneurotic edema, anaphylaxis); interstitial nephritis; jaundice; leukocytoclastic vasculitis; multiorgan failure; muscle injury and increased muscle enzymes; paranoia; peripheral neuropathy; photosensitivity/phototoxicity reactions; prolonged INR; prolonged PT; prolonged QT interval; pseudotumor cerebri; psychosis; rhabdomyolysis; serum sickness; severe dermatologic reactions (e.g., acute generalized exanthematous pustulosis [AGEP], fixed drug eruptions, erythema multiforme, toxic epidermal necrolysis [Lyell’s syndrome], Stevens-Johnson syndrome); tachycardia; tendon rupture; tinnitus; vasodilation; and isolated reports of allergic pneumonitis, encephalopathy, suicidal ideation, suicide attempts, completed suicide, and torsades de pointes.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically; monitor closely. Discontinue levofloxacin at the first sign of any major side effect (CDAD, CNS symptoms, dermatologic reactions, hepatotoxicity, hypersensitivity, hypoglycemic reactions, phototoxicity, symptoms of peripheral neuropathy, or tendon rupture). Treat hypersensitivity reactions as indicated with epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids, and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated. Mild cases of CDAD may respond to discontinuation of levofloxacin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Complete rest is indicated for an affected tendon until treatment is available. Maintain hydration in overdose. No specific antidote; not removed by hemodialysis or peritoneal dialysis. Maintain patient until drug is excreted and symptoms subside.

LEVOLEUCOVORIN

(lee-voh-loo-koh-**VOR**-in)
Fusilev, Khapzory
Folate analog
Antidote

USUAL DOSE

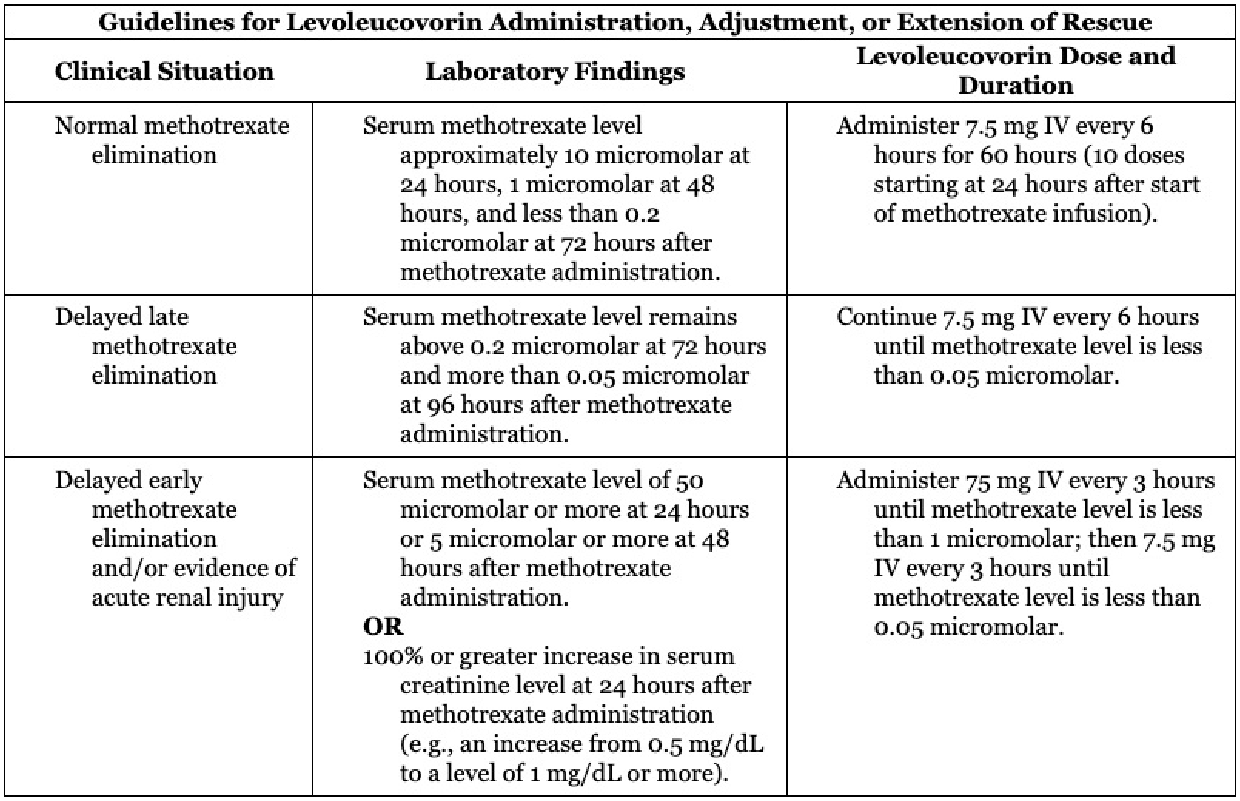
Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

Levoleucovorin, when substituted for leucovorin calcium, is dosed at one-half the usual dose of the racemic form (leucovorin calcium).

Levoleucovorin rescue after high-dose methotrexate therapy:

Dose is based on a methotrexate dose of 12 Gm/M^2 infused over 4 hours; see methotrexate monograph. Obtain serum creatinine and methotrexate levels at least once daily. Additional hydration and urinary alkalinization (pH 7 or greater) are indicated and should be continued until the methotrexate level is less than 0.05 micromolar. Twenty-four hours after starting the methotrexate infusion, initiate levoleucovorin rescue at a dose of 7.5 mg (approximately 5 mg/M^2) as an IV infusion every 6 hours. Administer and/or adjust the levoleucovorin dose or extend rescue based on the following guidelines. See Dose Adjustments, Precautions, and Monitor.



Guidelines for Levoleucovorin Administration, Adjustment, or Extension of Rescue

Clinical Situation	Laboratory Findings	Levoleucovorin Dose and Duration
Normal methotrexate elimination	Serum methotrexate level approximately 10 micromolar at 24 hours, 1 micromolar at 48 hours, and less than 0.2 micromolar at 72 hours after methotrexate administration.	Administer 7.5 mg IV every 6 hours for 60 hours (10 doses starting at 24 hours after start of methotrexate infusion).
Delayed late methotrexate elimination	Serum methotrexate level remains above 0.2 micromolar at 72 hours and more than 0.05 micromolar at 96 hours after methotrexate administration.	Continue 7.5 mg IV every 6 hours until methotrexate level is less than 0.05 micromolar.
Delayed early methotrexate elimination and/or evidence of acute renal injury	Serum methotrexate level of 50 micromolar or more at 24 hours or 5 micromolar or more at 48 hours after methotrexate administration. **OR** 100% or greater increase in serum creatinine level at 24 hours after methotrexate administration (e.g., an increase from 0.5 mg/dL to a level of 1 mg/dL or more).	Administer 75 mg IV every 3 hours until methotrexate level is less than 1 micromolar; then 7.5 mg IV every 3 hours until methotrexate level is less than 0.05 micromolar.

Treatment of folic acid antagonist overdose or impaired methotrexate elimination:

7.5 mg as an IV infusion every 6 hours (approximately 5 mg/M^2) until the serum methotrexate level is less than 5×10^{-8} M (0.05 micromolar). Begin levoleucovorin rescue in adult and pediatric patients as soon as possible after an overdose of methotrexate or within 24 hours of methotrexate administration when there is impaired methotrexate elimination. The effectiveness of levoleucovorin in diminishing toxicity may decrease as the time interval between methotrexate administration and levoleucovorin rescue increases. See Dose Adjustments and Monitor.

Colorectal cancer:

Several regimens are in use. See fluorouracil (5-FU) monograph for 5-FU specific information. Administer 5-FU and levoleucovorin separately to avoid the formation of a precipitate.

Flush the IV line with NS between drugs.

Levoleucovorin 100 mg/M² by IV injection over a minimum of 3 minutes (see Rate of Administration) followed by ***5-FU*** 370 mg/M² by IV injection ***or levoleucovorin*** 10 mg/M² by IV injection followed by ***5-FU*** at 425 mg/M² by IV injection. Repeat either regimen daily for 5 days. This 5-day course is repeated at 4-week intervals for 2 courses and then at 4- to 5-week intervals provided that complete recovery from the toxic effects of the previous course has occurred. See Dose Adjustments.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

Levoleucovorin rescue after high-dose methotrexate therapy:

Decreased methotrexate elimination or renal impairment, which are clinically important but less severe than abnormalities described in the preceding chart, can occur after methotrexate administration. These abnormalities may or may not be associated with significant clinical toxicity. If toxicity is observed, extend levoleucovorin rescue for an additional 24 hours (a total of 14 doses over 84 hours) in subsequent courses. If lab abnormalities or clinical toxicities are observed, consider the possibility that the patient is taking other medications that interact with methotrexate (e.g., medications that may interfere with methotrexate elimination or binding to serum albumin [see methotrexate monograph]). ■ Accumulation in a third space fluid collection (i.e., ascites, pleural effusion), inadequate hydration, or renal insufficiency can cause delayed methotrexate elimination. Higher doses of levoleucovorin or prolonged administration may be indicated.

Treatment of folic acid antagonist overdose or impaired methotrexate elimination:

Monitor serum creatinine and methotrexate levels at least every 24 hours. If the 24-hour serum creatinine has increased 50% over baseline or if the 24-hour methotrexate level is greater than 5×10^{-6} M or the 48-hour level is greater than 9×10^{-7} M, increase the dose of levoleucovorin to 50 mg/M² as an IV infusion every 3 hours until the methotrexate level is less than 10^{-8} M (0.01 micromolar). Hydrate with a minimum of 3 liters/day and use sodium bicarbonate for urinary alkalinization (adjust to maintain a urine pH of 7 or greater).

Colorectal cancer:

In subsequent courses, adjust the dose of 5-FU based on patient tolerance of the previous treatment course. Reduce 5-FU dose by 20% for patients who experienced moderate hematologic or GI toxicity in the previous course and 30% for patients who experienced severe toxicity. 5-FU dose may be increased by 10% if no toxicity was experienced in the previous course. Levoleucovorin doses are not adjusted for toxicity.

DILUTION

Fusilev for injection:

Available in a single-dose vial containing 50 mg of a lyophilized powder. Reconstitute each 50-mg vial with 5.3 mL of preservative-free NS (concentration equals 10 mg/mL). Do not use other diluents. A single dose may be further diluted immediately in NS or D5W to a concentration of 0.5 to 5 mg/mL.

Levoleucovorin for injection (generic):

Multiple manufacturers and strengths; consult individual prescribing information. Available in a single-dose vial containing 50 mg or 175 mg of a lyophilized powder. Reconstitute each 50-mg vial with 5.3 mL (175 mg with 17.7 mL) of preservative-free NS (concentration equals 10 mg/mL). Dilute immediately to a concentration of 0.5 to 5 mg/mL in NS or D5W. Also available as a solution in single-use vials containing 175 mg (17.5 mL) or 250 mg (25 mL). Concentration equals 10 mg/mL. A single dose may be further diluted to a concentration of 0.5 mg/mL in NS or D5W.

Fusilev injection:

Available as a solution in single-use vials containing 175 mg (17.5 mL) or 250 mg (25 mL). Concentration equals 10 mg/mL. A single dose may be further diluted to a concentration of 0.5 mg/mL in NS or D5W.

Khapzory:

Available in single-dose vials containing 175 mg or 300 mg of a lyophilized powder. Reconstitute each 175-mg vial with 3.6 mL (300-mg vial with 6.2 mL) of preservative-free NS. Concentration equals 50 mg/mL. Do not use other diluents. A single dose may be further diluted immediately in NS or D5W to a concentration of 0.5 to 5 mg/mL.

All formulations:

Do not use if solution is cloudy or if a precipitate is observed.

Filters:

Specific information not available.

Storage:

Consult individual product instructions in the package insert. Some formulations can be stored at CRT protected from light; others require refrigeration also protected from light. All formulations may be further diluted in NS or D5W protected from light, but storage times at RT differ.

COMPATIBILITY

Manufacturer states, “Due to the risk of precipitation, do not coadminister levoleucovorin with other agents in the same admixture.” Dilute only with preservative-free NS; do not use other diluents or NS with preservatives.

RATE OF ADMINISTRATION

Because of the calcium content of the solution, do not exceed a rate of administration of 16 mL/min of reconstituted solution (160 mg of levoleucovorin). When given in combination with 5-FU, flush the IV line with NS between drugs.

ACTIONS

A folate analog and the pharmacologically active levo-isomer of d,l-leucovorin. A replacement for leucovorin calcium, which also contains the pharmacologically inactive dextro isomer. Levoleucovorin does not require reduction by the enzyme dihydrofolate reductase. Levoleucovorin can counteract the therapeutic and toxic effects of folic acid antagonists such as methotrexate, which act by inhibiting dihydrofolate reductase. Also enhances the activity and toxicity of fluorouracil by stabilizing the binding of FdUMP (a fluorouracil metabolite) to thymidylate synthase (an enzyme important in DNA repair and replication), resulting in inhibition of this enzyme. Actively and passively transported across cell membranes. Terminal half-life is from 5.1 to 6.8 hours.

INDICATIONS AND USES

Rescue after high-dose methotrexate therapy in patients with osteosarcoma. ■ To diminish the toxicity associated with overdosage of folic acid antagonists (e.g., methotrexate, pemetrexed) or impaired methotrexate elimination. ■ Palliative treatment of patients with advanced metastatic colorectal cancer in combination with 5-fluorouracil.

Limitation of use:

Not indicated for the treatment of pernicious anemia or megaloblastic anemias secondary to vitamin B_{12} deficiency because of the risk of progression of neurologic manifestations despite hematologic remission.

CONTRAINDICATIONS

Contraindicated in patients who have had severe hypersensitivity reactions to leucovorin products, folic acid, or folinic acid.

PRECAUTIONS

For IV use only; do not administer by any other route. ■ Contains calcium; limit rate of administration to no more than 16 mL/min (160 mg of levoleucovorin per minute). ■ Levoleucovorin enhances the toxicities of fluorouracil. Although toxicities during combination use with 5-fluorouracil (5-FU) are similar to those observed with 5-FU alone, GI toxicities (particularly stomatitis and diarrhea) are observed more commonly and may be more severe or of prolonged duration. Deaths from severe enterocolitis, diarrhea, and dehydration have been reported. Do not initiate or continue therapy with levoleucovorin and fluorouracil in patients with symptoms of GI toxicity until those symptoms have resolved. ■ Seizures and/or syncope have been reported, usually in association with fluoropyrimidine administration and most commonly in patients with CNS metastases or other predisposing factors. ■ See Drug/Lab Interactions.

Monitor:

All situations with methotrexate:

Obtain baseline serum creatinine, electrolytes, and urine pH. Monitor SCr and methotrexate levels at least daily. ■ Adequate hydration and maintenance of a urinary pH of 7 or greater with sodium bicarbonate are indicated.

Levoleucovorin rescue after high-dose methotrexate therapy:

Patients who experience delayed early methotrexate elimination are likely to develop reversible renal failure. Continuing hydration and urinary alkalinization and monitoring of fluid and electrolyte status are required until the serum methotrexate level has fallen to below 0.05 micromolar and the renal failure has resolved.

Inadvertent methotrexate overdose:

See Dose Adjustments; hydration with a minimum of 3 liters/day and the use of sodium bicarbonate for urinary alkalinization (adjust to maintain a urine pH of 7 or greater) may be indicated.

Combination with 5-FU:

Monitor for S/S of GI toxicity. Monitor patients with diarrhea until it has resolved, because rapid deterioration leading to death can occur. See the 5-fluorouracil monograph for hematologic monitoring requirements.

Maternal/Child:

Use during pregnancy only if clearly needed. Levoleucovorin is administered in combination with methotrexate and fluorouracil, which can cause embryo-fetal harm. ■ Not known if levoleucovorin is excreted in human milk; has potential for harmful effects; discontinue breast-feeding. Levoleucovorin is administered in combination with methotrexate and fluorouracil. ■ Safety and effectiveness for use in pediatric patients have been established for rescue after high-dose methotrexate therapy in osteosarcoma and in diminishing toxicity associated with overdose of folic acid antagonists or impaired methotrexate elimination. Safety and effectiveness have not been established for the treatment of pediatric patients with advanced metastatic colorectal cancer; see literature.

Elderly:

Studies of levoleucovorin in the treatment of osteosarcoma did not include adults age 65 or older. ■ Deaths from severe dehydration, diarrhea, and severe enterocolitis have been reported in elderly patients receiving weekly leucovorin and fluorouracil.

DRUG/LAB INTERACTIONS

May ameliorate the hematologic toxicity associated with **high-dose methotrexate,** but levoleucovorin has no effect on other established toxicities of methotrexate, such as nephrotoxicity resulting from drug and/or metabolite precipitation in the kidney. ■ Folic acid in large amounts may counteract the antiepileptic effects of **phenobarbital, phenytoin, and primidone**. Seizure activity may be increased in susceptible patients. Levoleucovorin may or may not have the same effect due to shared metabolic pathways; use caution when administering concurrently with anticonvulsant drugs. ■ Leucovorin products increase the toxicities of **fluorouracil**; see Precautions. ■ Concomitant use with **sulfamethoxazole/trimethoprim** for the acute treatment of *Pneumocystis jiroveci* pneumonia in patients with HIV infection may cause treatment failure and morbidity. ■ Small amounts of systemically administered levoleucovorin may enter the cerebrospinal fluid (CSF). High doses of levoleucovorin may reduce the effectiveness of intrathecally administered **methotrexate.** ■ Levoleucovorin may enhance the toxic effects of **capecitabine**; monitor closely.

SIDE EFFECTS

Nausea and vomiting and stomatitis were reported most commonly. Abnormal renal function, confusion, dermatitis, diarrhea, dyspepsia, dyspnea, hypersensitivity reactions, neuropathy, taste perversion, and typhlitis (inflammation of the cecum) have been reported. Serious side effects reported include hypercalcemia and increased GI toxicities in combination with fluorouracil.

Combination therapy with 5-fluorouracil (5-FU):

Abdominal pain, alopecia, anorexia, dermatitis, diarrhea, fatigue, nausea, stomatitis, vomiting. Hypersensitivity reactions have been reported.

Post-Marketing:

Dyspnea, pruritus, rash, rigors, temperature change.

ANTIDOTE

Keep physician informed of patient’s condition. Symptomatic treatment and support may be indicated.

LEVOTHYROXINE SODIUM BBW

(lee-voh-thigh-**ROX**-een **SO**-dee-um)
T_4, L-Thyroxine
Hormone (thyroid)

USUAL DOSE

When oral ingestion is not practical, IV dose should be ½ of any previously established oral dose; see Indications and Uses, Limitation of Use. Adjust in small increments as indicated. Initiate oral treatment as soon as possible.

Hypothyroidism (when oral therapy is not possible):

Usual IV starting dose would be 6.25 to 12.5 mcg/day. Increase in increments of 12.5 mcg every 2 to 4 weeks. Base dosing on clinical response and serum thyroid and TSH levels. Average maintenance dose is 50 to 100 mcg/day PO.

Myxedema coma:

300 to 500 mcg as an initial dose. Follow with once-daily intravenous maintenance doses between 50 and 100 mcg.

PEDIATRIC DOSE

Given orally (may be crushed in food or liquid). See Precautions. Any IV dose should be 50% to 75% of the established oral dose. See pediatric literature for dosing guidelines.

DOSE ADJUSTMENTS

Age, general condition, cardiac risk factors, and clinical severity of myxedema symptoms should be considered when determining the starting and maintenance dosages. ■ Reduce dose in elderly, functional or ECG evidence of cardiovascular disease (including angina), long-standing thyroid disease, other endocrinopathies, and severe hypothyroidism. ■ See Drug/Lab Interactions.

DILUTION

Available in different strengths; read label carefully. Each vial of lyophilized powder is diluted with 5 mL of NS for injection (without preservatives). Shake well to dissolve completely. **Reconstituted concentrations will be 20 mcg/mL for the 100-mcg vial and 100 mcg/mL for the 500-mcg vial.** Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

Storage:

Store dry product at CRT and protect from light. Reconstituted solution is preservative-free and stable for 4 hours; any remaining solution is discarded.

COMPATIBILITY

Manufacturer states, “Do not add to other IV fluids.”

RATE OF ADMINISTRATION

100 mcg or fraction thereof over 1 minute.

ACTIONS

A synthetic thyroid hormone. Effective replacement for decreased or absent thyroid hormone. Thyroid hormone synthesis and secretion is regulated by the hypothalamic-pituitary-thyroid axis. Thyroid hormones regulate multiple metabolic processes and play an essential role in normal growth and development. Actions are produced predominantly by T_3 (triiodothyronine). Approximately 80% of T_3 is derived from T_4 (levothyroxine) by deiodination in peripheral tissues. The metabolic actions of thyroid hormones include augmentation of cellular respiration and thermogenesis, as well as metabolism of proteins, carbohydrates, and lipids. Circulating thyroid hormones are greater than 99% bound to plasma proteins (thyroxine-binding globulin [TBG], thyroxine-binding prealbumin [TBPA], and albumin [TBA]). The higher affinity of both TBG and TBPA for T_4 partially explains the higher serum levels, slower metabolic clearance, and longer half-life of T_4 (6 to 8 days) compared with T_3 (less than 2 days). The major pathway of thyroid hormone metabolism is through sequential deiodination. The liver is the major site of degradation for both T_4 and T_3. Primary route of elimination is through the kidneys. Small amounts are eliminated into the bile and feces.

INDICATIONS AND USES

Treatment of myxedema coma. ■ Specific replacement therapy for reduced or absent thyroid function due to any cause (usually given orally).

Limitation of use:

The relative bioavailability between oral and intravenous levothyroxine sodium for injection has not been established but has been estimated to be between 48% and 74%. Caution should be used when switching patients from oral products to the parenteral product because adequate dosing conversions have not been studied.

CONTRAINDICATIONS

None. ■ Not indicated for use in treatment of obesity. Risk can outweigh benefit.

PRECAUTIONS

Excessive bolus doses (greater than 500 mcg) are associated with cardiac complications, particularly in the elderly and in patients with underlying cardiac disease; see Dose Adjustments. ■ Patients with undiagnosed endocrine disorders (e.g., adrenal insufficiency, hypopituitarism, diabetes insipidus) may experience new or worsening symptoms of these endocrinopathies. Patients should be treated with replacement glucocorticoids before initiation of treatment with levothyroxine until adrenal function has been adequately assessed. Failure to do so may precipitate an acute adrenal crisis when thyroid hormone therapy is initiated as a result of increased metabolic clearance of glucocorticoids by thyroid hormone. Patients with myxedema coma should be monitored for previously undiagnosed diabetes insipidus. ■ Not indicated for treatment of obesity or for weight loss. Doses within the range of daily hormonal requirements are ineffective for weight reduction. Larger doses may produce serious or even life-threatening manifestations of toxicity, particularly when given in conjunction with sympathomimetic amines, such as those used for the anorectic effects.

Monitor:

Observe patient closely and monitor vital signs. ■ Monitor thyroid function tests (e.g., free T_4 index, TSH). ■ TSH and thyroid hormone levels should be measured a few weeks after switching from IV to oral therapy. Adjust dose according to results and clinical status. ■ Monitor TSH every 6 to 8 weeks until normalized, every 8 to 12 weeks after dose changes, and every 6 to 12 months throughout therapy.

Maternal/Child:

Category A: may be used during pregnancy. ■ Presumed safe in breast-feeding; use caution and observe infant. ■ Myxedema coma is a disease of the elderly. An approved oral dosage form should be used in pediatric patients for maintaining a euthyroid state in noncomplicated hypothyroidism; see Pediatric Dose.

Elderly:

See Dose Adjustments; more sensitive to effects. Atrial fibrillation is a common side effect associated with levothyroxine treatment in the elderly.

DRUG/LAB INTERACTIONS

Addition of levothyroxine to **antidiabetic or insulin** therapy may result in increased antidiabetic or insulin requirements. Monitor glucose values closely, especially when thyroid therapy is initiated, changed, or discontinued. ■ Levothyroxine increases response to **oral anticoagulant** therapy (e.g., warfarin). Reduction in dose of oral anticoagulant may be required. Monitor PT/INR. ■ May decrease therapeutic effects of **digoxin**, necessitating an increase in the digoxin dose. Monitor serum digoxin levels. ■ Concurrent use of **tricyclic** (e.g., amitriptyline) or **tetracyclic** (e.g., maprotiline) **antidepressants** and levothyroxine may increase the therapeutic and toxic effects of both drugs, possibly due to increased receptor sensitivity to catecholamines. ■ Administration of **sertraline** in patients stabilized on levothyroxine may result in increased levothyroxine requirements. ■ Concurrent use with **ketamine** may produce marked hypertension and tachycardia. Use caution. ■ Concurrent use with **sympathomimetics** (e.g., epinephrine, norepinephrine) may increase the effects of sympathomimetics or thyroid hormone. May increase risk of coronary insufficiency. ■ **Carbamazepine, fosphenytoin, phenytoin, and rifampin** may decrease the serum concentration of thyroid hormones. Monitor levels closely. ■ Levothyroxine can increase the metabolism of **theophylline**, necessitating an increase in theophylline dose. Monitor theophylline levels. ■ Changes in TBG concentration must be considered when interpreting T_3 and T_4 values, which necessitates measurement and evaluation of unbound (free) hormone and/or determination of the free levothyroxine index. Several medications and disease states can alter TBG concentrations. See manufacturer's prescribing information.

SIDE EFFECTS

Abdominal cramps, angina, arrhythmias, chest pain, diarrhea, heart palpitations, heat intolerance, increased pulse and BP, insomnia, menstrual irregularities, muscle cramps, nervousness, sweating, tachycardia, tremors, vomiting, and weight loss.

ANTIDOTE

Notify the physician of any side effect. A reduction in dose will usually decrease symptoms. Supportive treatment should be initiated as dictated by the patient's medical status.

LIDOCAINE HYDROCHLORIDE

(**LYE**-doh-kayn hy-droh-**KLOR**-eyed)
Lidocaine PF, Xylocaine PF, Xylocard 🍁
Antiarrhythmic
pH 5 to 7 (Injection) 3 to 7 (IV infusion)

USUAL DOSE

1 to 1.5 mg/kg of body weight as a ***bolus dose.*** ACLS guidelines recommend repeat doses of 0.5 to 0.75 mg/kg every 5 to 10 minutes to desired effect, up to a maximum cumulative dose of 3 mg/kg. Follow with a continuous infusion of 1 to 4 mg/min (0.02 to 0.05 mg/kg/min in an average 70-kg adult). Transition to maintenance oral antiarrhythmic therapy as soon as possible. Infusions beyond 24 hours should rarely be needed; see Dose Adjustments. Exact dosage regimen is determined by patient characteristics and response.

Perfusing arrhythmia (stable VT, wide-complex tachycardia of uncertain type, significant ectopy):

AHA guidelines recommend doses ranging from 0.5 to 0.75 mg/kg and up to 1 to 1.5 mg/kg. Repeat 0.5 to 0.75 mg/kg every 5 to 10 minutes to a maximum total dose of 3 mg/kg. Follow with a continuous infusion of 1 to 4 mg/min (20 to 50 mcg/kg/min).

PEDIATRIC DOSE

See Maternal/Child (unlabeled).

Antiarrhythmic:

AHA recommends 1 mg/kg as an IV bolus followed immediately by an infusion of 20 to 50 mcg/kg/min (average of 30 mcg/kg/min). If 15 minutes have elapsed since the initial bolus dose before the infusion is started, administration of an additional bolus (1 mg/kg) is recommended when the infusion is initiated.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in elderly patients based on potential for decreased organ function and concomitant disease or drug therapy. ■ Reduce maintenance dose in patients with impaired liver function or severe renal impairment and in patients receiving drugs that may decrease clearance of lidocaine or decrease liver blood flow (e.g., beta-blockers [propranolol, cimetidine]). ■ Reduce infusion rate by approximately one-half after prolonged infusion (24 hours) to compensate for decreased rate of clearance (accumulation of the drug) and potential toxicity.

DILUTION

Available premixed in 0.4% or 0.8% solutions (4 or 8 mg/mL) and as prefilled syringes. Label must state “for IV use” and be preservative free. Bolus dose may be given undiluted.

Filters:

One PI states “Use of a final filter is recommended, where possible.” Another source suggests use of a 0.45 micron cellulose membrane filter.

Storage:

Store at CRT. Protect from freezing.

COMPATIBILITY

Manufacturer states, “Because doses of lidocaine are titrated to response, additives should not be introduced into solutions of lidocaine.” Should not be added to blood transfusion assemblies because of the possibilities of pseudoagglutination or hemolysis.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Bolus dose:

25 to 50 mg or fraction thereof over 1 minute.

Infusion:

1 to 4 mg/min (0.02 to 0.05 mg/kg/min in an average 70-kg adult). Use of a calibrated infusion device recommended. Adjust as indicated by progress in patient’s condition; see Dose Adjustments.

IV infusions in flexible plastic containers:

With or without a pump:

Do not hang in series connection, do not pressurize to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets. All may result in air embolism.

ACTIONS

Intravenous lidocaine exerts an antiarrhythmic effect by increasing the electric stimulation threshold of the ventricle during diastole. In usual therapeutic doses, produces no change in myocardial contractility, systemic arterial pressure, or absolute refractory period. Decreases neuronal membrane permeability to sodium ions, resulting in inhibition of depolarization. Plasma protein binding is concentration dependent; fraction bound decreases with increasing concentration. Onset of action should occur within 1 to 2 minutes and last approximately 10 to 20 minutes. Terminal half-life is 1.5 to 2 hours. Primarily metabolized in the liver. Excreted in the urine with about 10% excreted unchanged and 90% excreted as various metabolites. Crosses the blood-brain and placental barriers and is secreted in breast milk.

INDICATIONS AND USES

Acute management of life-threatening ventricular arrhythmias (e.g., ventricular tachycardia [VT], ventricular fibrillation [VF]), such as occur during acute myocardial infarction, or ventricular arrhythmias occurring during cardiac manipulations such as cardiac surgery.

Unlabeled uses:

Pediatric ventricular arrhythmias, seizures unresponsive to other therapy.

CONTRAINDICATIONS

Known sensitivity to lidocaine or any other local anesthetic of the amide type. ■ Patients with Stokes-Adams syndrome, Wolff-Parkinson-White syndrome, or severe degrees of sinoatrial, atrioventricular, or intraventricular block. ■ Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Administered by health care professionals knowledgeable in its use with access to adequate equipment and appropriate emergency drugs to monitor the patient and respond to any medical emergency. ■ In patients with bradycardia or incomplete heart block, administration of lidocaine for the elimination of ventricular ectopic beats without prior acceleration in heart rate (e.g., by isoproterenol or electric pacing) may promote more frequent and serious ventricular arrhythmias or complete heart block. ■ Acceleration of ventricular rate may occur in patients with atrial fibrillation or flutter treated with lidocaine. ■ Use caution in patients with any degree of liver impairment or severe renal impairment; accumulation may occur and lead to toxicity. ■ Systemic toxicity (usually with plasma levels above 6 mcg/mL) may result in CNS depression (sedation) or irritability (twitching). May progress to frank convulsions with respiratory depression and/or arrest. ■ Has been associated with malignant hyperthermia. ■ Hypersensitivity reactions, including anaphylaxis, have been reported.

Monitor:

Monitor ECG continuously. ■ Discontinue lidocaine when patient’s cardiac condition is stable or any signs of toxicity become apparent (signs of excessive depression of cardiac conductivity, such as prolongation of the PR interval, widening of the QRS interval, or appearance or aggravation of arrhythmias). ■ Therapeutic serum levels range from 1.5 to 5 mcg/mL; above 6 mcg/mL is usually toxic. ■ Monitor electrolytes, fluid balance, and acid-base balance. ■ Half-life increases over time. Reduce rate of continuous infusion after 24 hours and monitor blood levels. ■ Keep patient lying down to reduce hypotensive effects. ■ Monitor for S/S of hypersensitivity (e.g., large hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face). ■ Discontinue infusion if malignant hyperthermia develops and treat as appropriate. ■ See Drug Interactions.

Patient Education:

May cause dizziness; remain at bed rest; request assistance if ambulation permitted.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Present in human milk. Safety for use in breast-feeding, the effects on the breast-fed infant, or the effects on milk production are unknown. Consider risk versus benefit. ■ Safety for use in pediatric patients not established.

Elderly:

Data are limited. Difference in responses between elderly patients and younger patients has not been identified. Lower-end initial dosing may be appropriate. See Dose Adjustments. ■ Consider age-related renal and hepatic impairment.

DRUG/LAB INTERACTIONS

Administration with other **antiarrhythmic agents** (e.g., amiodarone, procainamide, propranolol, quinidine) may result in additive or antagonistic cardiac effects, and toxic effects may be additive. ■ Concomitant use with **inhibitors of CYP1A2** (such as fluvoxamine) **and/or CYP3A4** (such as propofol) may decrease lidocaine clearance, increase lidocaine plasma levels, and prolong the elimination half-life. Monitor for toxicity with concurrent use. ■ Concomitant use with **inducers of CYP1A2 and/or CYP3A4** (e.g., phenytoin) may decrease lidocaine plasma levels, and higher doses of lidocaine may be required. ■ Concomitant use with a **weak CYP1A2 and CYP3A4 inhibitor** (e.g., cimetidine) may decrease clearance and increase lidocaine plasma levels, by 24% to 75%, resulting in toxic accumulation of lidocaine. Monitor lidocaine serum concentrations and monitor closely for signs of toxicity. ■ Concomitant use with **beta-adrenergic blockers** may increase lidocaine plasma levels by decreasing hepatic blood flow resulting in decreased lidocaine clearance. Monitor for toxicity when co-administering lidocaine with **drugs that decrease hepatic blood flow**. ■ May potentiate neuromuscular blockade of succinylcholine. ■ Monitor toxicity when lidocaine is used in patients with digitalis toxicity accompanied by supraventricular arrhythmia and/or atrioventricular block; see Contraindications.

SIDE EFFECTS

Side effects include agitation; apprehension; asystole; blurred or double vision; bradycardia; cardiac arrest; confusion; convulsions; disorientation; dizziness; drowsiness; dysarthria; euphoria; hypoesthesia (oral); hypotension; light-headedness; malignant hyperthermia (tachycardia, tachypnea, metabolic acidosis, fever); methemoglobinemia; nausea; paresthesia; prolonged PR interval; QRS complex widening; respiratory depression and arrest; sensations of heat, cold, and numbness; tinnitus; tremors; twitching; unconsciousness; ventricular arrhythmia; VF; VT; and vomiting. Hypersensitivity reactions, including anaphylaxis, have been reported (infrequent). Cross-sensitivity between lidocaine and procainamide or between lidocaine and quinidine has not been reported.

Overdose:

In addition to many of the previously listed side effects, arrhythmias (including asystole, bradycardia, heart block, tachycardia, and ventricular arrhythmias), cardiorespiratory arrest (sometimes fatal), cardiovascular collapse, CNS depression, coma, myocardial depression, nystagmus, and tingling of the tongue and lips have been reported.

ANTIDOTE

Notify the physician of any side effects. For major side effects, discontinue the drug immediately and institute appropriate measures. Ensure patency of airway and adequacy of ventilation. Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. There is no specific antidote for overdose of lidocaine. Maintain and support patient using appropriate corrective, resuscitative, and other supportive measures.

LINCOMYCIN HYDROCHLORIDE BBW

(link-oh-**MY**-sin hy-droh-**KLOR**-eyed)
Lincocin
Antibacterial (lincosamide)
pH 3 to 5.5

USUAL DOSE

Doses based on severity of the infection.

Serious infections:

600 mg to 1 Gm every 8 to 12 hours.

More serious infections:

Above doses may be increased.

Life-threatening infections:

Total doses up to 8 Gm/24 hr have been used.

PEDIATRIC DOSE

Pediatric patients over 1 month of age:

10 to 20 mg/kg of body weight/24 hr divided into 2 or 3 doses (5 to 10 mg/kg every 12 hours or 3.33 to 6.66 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Reduce dose to 25% to 30% of the recommended dose in patients with severe impaired renal function.

DILUTION

Each 1 Gm or fraction thereof must be diluted with 100 mL of D5W, D5NS, or other **compatible** solution (e.g., 2 Gm in 200 mL, 3 Gm in 300 mL, 4 Gm in 400 mL).

Storage:

Prior to dilution, store at CRT. Stable at CRT for up to 24 hours in **compatible** diluents and infusion solutions.

COMPATIBILITY

Manufacturer lists as **incompatible** with kanamycin and novobiocin. Manufacturer lists the following **compatibilities:**

Solutions:

D5W, D10W, D5NS, D10NS.

Additive:

Ampicillin, cephaloridine, cephalothin, colistimethate (4 hours), chloramphenicol, methicillin, penicillin G (4 hours), polymyxin B sulfate, tetracycline HCl, vitamin B-complex, vitamin B-complex with ascorbic acid. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Severe hypotension, syncope, other cardiopulmonary reactions and cardiac arrest can occur with too-rapid injection. Infuse properly diluted solution at a rate not to exceed 100 mL/hr (1 Gm/hr).

ACTIONS

Interferes with bacterial protein synthesis. Inhibits protein synthesis by binding to the 23S RNA of the 50S subunit of the bacterial ribosome. May be bactericidal or bacteriostatic. A single dose yields therapeutic concentrations for up to 14 hours and has a half-life of 4.4 to 6.4 hours. Well distributed in most body tissues but has poor CNS penetration. Partially metabolized in the liver and excreted in urine and bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections due to susceptible strains of streptococci, pneumococci, and staphylococci. It should be reserved for patients allergic to penicillins or in patients whose infections do not respond to or are resistant to other less toxic antibiotics such as erythromycin or penicillins. Reserve use for serious infections in which less toxic antimicrobial agents are inappropriate.

CONTRAINDICATIONS

Known hypersensitivity to lincomycin or clindamycin. ■ Not indicated for the treatment of meningitis, minor bacterial infections, or viral infections. ■ Should not be used in patients with nonbacterial infections (e.g., most upper respiratory tract infections).

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, lincomycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to lincomycin. ■ Cross-resistance has been demonstrated between lincomycin and clindamycin and between lincomycin and erythromycin. ■ Has been associated with severe colitis, which may be fatal. ■ Use caution in patients with a history of GI disease (e.g., colitis) or severe renal or liver disease and in patients with a history of asthma or significant allergies. ■ Certain infections may require incision and drainage or other indicated surgical procedures in addition to antibacterial therapy. ■ Severe hypersensitivity reactions, including anaphylaxis, and severe cutaneous adverse reactions (SCAR) such as acute generalized exanthematous pustulosis (AGEP), erythema multiforme (EM), Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN) have been reported. ■ Half-life may be extended twofold in patients with severe renal or hepatic impairment. ■ Avoid prolonged use; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or following treatment with lincomycin. Because lincomycin therapy has been associated with severe colitis (which may end fatally), it should be reserved for serious infections in which less toxic antimicrobial agents are inappropriate. ■ Concurrent anti-monilial treatment is indicated in patients with pre-existing monilial infections. ■ See Maternal/Child.

Monitor:

Avoid hypotension by keeping the patient lying down during the infusion and monitoring the rate of infusion carefully. ■ Observe carefully for S/S of a hypersensitivity reaction (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing) and S/S of severe cutaneous reactions (e.g., SCAR, AGEP, SJS, TEN). ■ Periodic blood cell counts and liver and kidney studies are indicated in prolonged therapy. ■ Capable of causing severe or even fatal colitis; observe for symptoms of diarrhea; see Elderly. ■ Dose patients with severe renal function and/or abnormal hepatic function with caution and monitor serum lincomycin levels during high-dose therapy.

Patient Education:

Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Do not treat diarrhea without notifying physician.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Discontinue breast-feeding; has potential for serious adverse reactions in nursing infants. ■ Contains benzyl alcohol, which has been associated with serious adverse events, including “gasping syndrome” and death in pediatric patients. Premature and low-birth-weight infants may be more likely to develop toxicity. Safety and effectiveness in pediatric patients under 1 month of age have not been established.

Elderly:

Dose selection should be cautious; see Dose Adjustments. Consider age-related organ impairment. ■ Monitor carefully for changes in bowel frequency; may not tolerate diarrhea well.

DRUG/LAB INTERACTIONS

Has neuromuscular blocking properties and may have additive effects with **other neuromuscular blocking agents** (e.g., atracurium, aminoglycosides); apnea can result.

SIDE EFFECTS

Abdominal discomfort; abdominal pain; agranulocytosis; aplastic anemia; azotemia; cardiorespiratory arrest; CDAD; diarrhea; dizziness; elevated liver function tests (e.g., ALT, AST, transaminases); glossitis; headache; hypersensitivity reactions (including anaphylaxis and angioedema); hypotension; injection site abscess (sterile), induration, irritation, and pain; jaundice; leukopenia; nausea; neutropenia; oliguria; pancytopenia; proteinuria; pruritus; pseudomembranous colitis; renal impairment; rash; serum sickness; severe skin and subcutaneous tissue disorders (e.g., AGEP, dermatitis bullous, dermatitis exfoliative, erythema multiforme, SJS, TEN); somnolence; stomatitis; thrombocytopenic purpura; tinnitus; urticaria; vaginal infection; vertigo; vomiting.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated (e.g., hypersensitivity reactions, colitis, diarrhea, severe skin reactions). Treat allergic reactions as indicated (e.g., epinephrine, corticosteroids, antihistamines [e.g., diphenhydramine], airway management, oxygen, IV fluids, and BP support [e.g., dopamine]). Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Initiate appropriate therapy if severe skin reactions occur. Resuscitate as necessary. Hemodialysis or CAPD is not effective in overdose and will not decrease blood levels in toxicity.

LINEZOLID

(lih-**NAY**-zoh-lid)
Zyvox
Antibacterial (oxazolidinone)
pH 4.8

USUAL DOSE

Dose and duration of therapy are based on diagnosis and designated pathogens. May be transferred to oral dosing when appropriate; no dose adjustment is necessary. See Precautions.

Recommended Linezolid Doses in Pediatric and Adult Patients			
Infection[a]	**Dosage and Route of Administration**		**Recommended Duration of Treatment (Consecutive Days)**
Complicated skin and skin structure infections	10 mg/kg IV or PO[c] q 8 hr	600 mg IV or PO[c] q 12 hr	10 to 14
Community-acquired pneumonia, including concurrent bacteremia			
Nosocomial pneumonia			
Vancomycin-resistant *Enterococcus faecium* infections, including concurrent bacteremia	10 mg/kg IV or PO[c] q 8 hr	600 mg IV or PO[c] q 12 hr	14 to 28
Uncomplicated skin and skin structure infections	Under 5 years: 10 mg/kg PO[c] q 8 hr 5 to 11 years: 10 mg/kg PO[c] q 12 hr	Adults: 400 mg PO[c] q 12 hr Adolescents: 600 mg PO[c] q 12 hr	10 to 14

[a] Due to the designated pathogens (see Indications and Uses and package insert).

[b] Neonates under 7 days of age: Most preterm neonates under 7 days of age (gestational age under 34 weeks) have lower systemic linezolid clearance values and larger AUC values than many full-term neonates and older infants. These neonates should be initiated with a dosing regimen of 10 mg/kg q 12 hr. Consideration may be given to the use of 10 mg/kg q 8 hr regimen in neonates with a suboptimal clinical response. All neonatal patients should receive 10 mg/kg q 8 hr by 7 days of life.

[c] Oral dosing using either linezolid tablets or linezolid for oral suspension.

PEDIATRIC DOSE

See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Dose adjustment based on age, gender, renal insufficiency, or hepatic insufficiency is not required. ■ 30% of a dose is removed during a 3-hour dialysis session. Administer linezolid after hemodialysis.

DILUTION

Available in ready-to-use flexible plastic infusion bags in a foil laminate overwrap. Available as a 2 mg/mL solution in 200- and 600-mg infusion bags. Before use, remove overwrap and check for leaks by squeezing the bag. Each overwrap contains a peel-off label that should be applied to the infusion bag for barcode scanning before use. Do not use flexible containers in series connections.

Storage:

Store at CRT. Protect from light and freezing. Keep in overwrap until ready to use. Solution may exhibit a yellow color that can intensify with time. Will not adversely affect potency.

COMPATIBILITY

Additives should not be introduced into this solution. If administered through the same tubing as other medications, flush line before and after infusion of linezolid with a solution that is **compatible** with linezolid (e.g., D5W, NS, LR) and with any medications administered through the common line. **Incompatible** at the **Y-site** with amphotericin B, ceftriaxone, chlorpromazine, diazepam, erythromycin, pentamidine, phenytoin, and sulfamethoxazole/trimethoprim.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an infusion over 30 to 120 minutes. Flush line before and after administration if indicated; see Compatibility.

ACTIONS

A synthetic antibacterial agent. The first agent of a new class of antibiotics, the oxazolidinones. Clinically useful in the treatment of infections caused by aerobic gram-positive bacteria. See Indications and Uses and manufacturer's literature. Inhibits bacterial protein synthesis through a mechanism of action different from that of other antibacterial agents; therefore cross-resistance between linezolid and other classes of antibiotics is unlikely. Bacteriostatic against enterococci and staphylococci. Bactericidal against most strains of streptococci. Readily distributes into well-perfused tissues. Metabolized to two inactive metabolites. Metabolic pathway is not fully understood. Half-life is 4.8 hours. Approximately 30% of a dose is excreted in the urine as linezolid and 50% is excreted as metabolites.

INDICATIONS AND USES

Treatment of adults, adolescents, and other pediatric patients with the following infections caused by susceptible strains of the designated microorganisms: vancomycinresistant *Enterococcus faecium* infections, including cases with concurrent bacteremia; nosocomial pneumonia caused by *Staphylococcus aureus* (methicillin-susceptible and methicillin-resistant strains) or *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP]); complicated skin and skin-structure infections (including diabetic foot infections without concomitant osteomyelitis) caused by *Staphylococcus aureus* (methicillin-susceptible and methicillin-resistant strains), *Streptococcus pyogenes,* or *Streptococcus agalactiae;* uncomplicated skin and skin-structure infections caused by *Staphylococcus aureus* (methicillin-susceptible strains only) or *Streptococcus pyogenes;* and community-acquired pneumonia caused by *Streptococcus pneumoniae* (including multidrug-resistant strains [MDRSP] and cases with concurrent bacteremia) or *Staphylococcus aureus* (methicillin-susceptible strains only). ■ Treatment of decubitus ulcers has not been studied. ■ Given orally to treat uncomplicated skin and skin-structure infections. ■ Not indicated for treatment of gram-negative infections. Critical that specific gram-negative therapy be initiated immediately if a concomitant gram-negative pathogen is documented or suspected. ■ Not approved for and should not be used for treatment of patients with catheter-related bloodstream infections or catheter-site infections.

CONTRAINDICATIONS

History of hypersensitivity to linezolid or any of its components. ■ Avoid use in patients taking any medicinal products that inhibit monoamine oxidase A or B (e.g., isocarboxazid, phenelzine) or within 2 weeks of taking any such product. ■ Unless closely monitored for potential increases in BP, avoid use in patients with uncontrolled hypertension, pheochromocytoma, or thyrotoxicosis and/or in patients taking any of the following types of medications: directly and indirectly acting sympathomimetic agents (e.g., pseudoephedrine), vasopressive agents (e.g., epinephrine, norepinephrine), dopaminergic agents (e.g., dobutamine, dopamine); see Precautions and Drug/Lab Interactions. ■ Unless closely monitored for S/S of serotonin syndrome or neuroleptic malignant syndrome–like (NMS-like) reactions, avoid use in patients with carcinoid syndrome and/or in patients taking any of the following medications: serotonin reuptake inhibitors, tricyclic antidepressants, serotonin 5-HT_1 receptor agonists, meperidine, or buspirone; see Precautions and Drug/Lab Interactions.

PRECAUTIONS

Culture and sensitivity studies are indicated to determine susceptibility of the causative organism to linezolid. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, linezolid should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Reports of vancomycin-resistant *Enterococcus faecium* (VRE) becoming resistant to linezolid during its clinical use have been published. ■ There has been a report of methicillin-resistant *Staphylococcus aureus* (MRSA) developing resistance to linezolid during its clinical use. ■ Combination therapy may be clinically indicated in treatment of nosocomial pneumonia or complicated skin and skin-structure infections if the documented or presumptive pathogens include gram-negative organisms. ■ Should not be used for treatment of patients with catheter-related bloodstream infections or catheter site infections. ■ Myelosuppression (including anemia, leukopenia, pancytopenia, and thrombocytopenia) has been reported; see Monitor. ■ Hypoglycemia, including symptomatic episodes, has been reported in patients with diabetes who have been treated with insulin or oral hypoglycemic agents and linezolid; see Monitor and Drug/Lab Interactions. ■ Use with caution in patients with renal failure. Although dose adjustments are not recommended in this patient population, the metabolites may accumulate. The clinical significance of this accumulation is unknown. Dose should be given after hemodialysis. ■ Use with caution in patients with uncontrolled hypertension, severe hepatic insufficiency, pheochromocytoma, carcinoid syndrome, or untreated hyperthyroidism; see Contraindications. Use has not been studied in these patient populations. ■ Safety and efficacy of linezolid given for longer than 28 days have not been evaluated. ■ Neuropathy (peripheral and optic) has been reported, primarily in patients treated for longer than the maximum recommended duration of 28 days. May occur in patients treated with linezolid for shorter periods, as well as in patients treated for more than 28 days. ■ Superinfection, caused by the overgrowth of nonsusceptible organisms, may occur with antibiotic use. Treat as indicated. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with linezolid. ■ Lactic acidosis has been reported. In most cases, patients experienced repeated episodes of N/V. ■ Serotonin syndrome (including fatal cases) and neuroleptic malignant syndrome–like (NMS-like) reactions have been reported in patients receiving linezolid and concomitant serotonergic agents; see Contraindications, Monitor, and Drug/Lab Interactions. ■ Convulsions have been reported; however, a history of seizures was reported in some of the cases. ■ See Monitor, Patient Education, and Drug/Lab Interactions.

Monitor:

CBC with differential and platelet count should be monitored weekly, especially in patients who receive linezolid for longer than 2 weeks; those with pre-existing myelosuppression; those receiving concomitant drugs that produce bone marrow suppression (e.g., antineoplastics, chloramphenicol, immunosuppressants) or affect platelet function (e.g., aspirin, NSAIDs, platelet aggregation inhibitors, selected antibiotics, valproic acid); or those with a chronic infection who have received previous or concomitant antibiotics. Consider discontinuing therapy in patients who develop or have worsening myelosuppression. Myelosuppression appears to be reversible following discontinuation of linezolid. ■ Monitor patients with diabetes who are receiving insulin or hypoglycemic agents for hypoglycemia; see Drug/Lab Interactions. ■ Monitoring of visual function is recommended in patients taking linezolid for extended periods (3 months or more). Prompt ophthalmic evaluation is recommended if symptoms of visual impairment appear (e.g., blurred vision, changes in visual acuity or color vision, or visual field defect). ■ Monitor for S/S of lactic acidosis (e.g., recurrent N/V, unexplained acidosis, or a low bicarbonate level); immediate medical evaluation is indicated. ■ Monitor for S/S of serotonin syndrome or NMS-like reactions (autonomic instability, hyperthermia, myoclonus, rigidity, and mental status changes that include extreme agitation progressing to delirium and coma) when administered concurrently with serotonergic agents; see Drug/Lab Interactions. ■ Monitor dietary intake of tyramine; see Patient Education. Hypertension may result from excessive tyramine intake (less than 100 mg/day). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Avoid foods or beverages high in tyramine (e.g., aged cheeses, fermented or air-dried meats, sauerkraut, soy sauce, tap beers, red wines). ■ Inform physician of any history of hypertension or seizures. See Precautions. ■ Inform physician if taking any medications containing pseudoephedrine or phenylpropanolamine (found in many cold or allergy preparations or diet aids), if taking serotonin reuptake inhibitors (e.g., fluoxetine, sertraline, paroxetine) or other antidepressants, or if taking an antidiabetic agent (e.g., insulin or an oral hypoglycemic agent). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report any hypoglycemic reactions (e.g., diaphoresis and tremulousness) along with low blood glucose measurements. ■ Report any vision changes promptly. See Drug Interactions.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established; benefits must outweigh risks. ■ Volume of distribution is similar regardless of age in pediatric patients; however, clearance varies as a function of age. With the exception of preterm neonates under 1 week of age, clearance is most rapid in the youngest age-groups (ranging from under 1 week to 11 years of age), resulting in lower single-dose systemic exposure (AUC) and a shorter half-life. ■ Most preterm neonates under 7 days of age (gestational age under 34 weeks) have lower systemic linezolid clearance values and larger AUC values than many full-term neonates and older infants; see Usual Dose. ■ AUC values in patients from birth to 11 years of age dosed every 8 hours are similar to adolescents and adults dosed every 12 hours. ■ Therapeutic concentrations are not consistent in CSF; not indicated for empiric treatment of CNS infections in pediatric patients.

Elderly:

No overall difference in safety or effectiveness has been observed between these patients and younger patients. Pharmacokinetics is not significantly altered in the elderly. See Dose Adjustments.

DRUG/LAB INTERACTIONS

Linezolid is a reversible, nonselective inhibitor of monoamine oxidase and therefore has the potential to interact with **adrenergic and serotonergic agents and with tyramine-containing foods.** ■ A reversible enhancement of the pressor response to **indirect-acting sympathomimetic agents or vasopressor or dopaminergic agents** (e.g., pseudoephedrine, epinephrine, dopamine) may be seen with concomitant use. Initial doses of adrenergic agents, such as epinephrine or dopamine, should be reduced and titrated to achieve the desired response; see Contraindications. ■ Serotonin syndrome has been reported in patients receiving concurrent therapy with linezolid and **selective serotonin reuptake inhibitors** (SSRIs) or **serotonin norepinephrine reuptake inhibitors** (SNRIs). Linezolid use in patients taking serotonergic drugs should be limited to life-threatening or urgent situations in which linezolid is considered to be the drug of choice (e.g., treatment of vancomycin-resistant enterococcus [VRE] infections, serious infections such as nosocomial pneumonia, or complicated skin and skin structure infections, including cases caused by MRSA). The serotonergic agent should be stopped promptly when linezolid therapy is initiated. Patients should be monitored for the development of serotonin syndrome for 2 weeks (5 weeks if fluoxetine was taken) or until 24 hours after the last dose of linezolid, whichever comes first. If S/S of serotonin syndrome develop, consider discontinuing linezolid. Patients should also be monitored for specific symptoms due to discontinuation of the serotonergic agent; see prescribing information for the specific agent; see Contraindications and Monitor. ■ May cause hypoglycemia with **insulin or hypoglycemic agents.** Dose reduction or discontinuation of the antidiabetic agent and/or discontinuation of linezolid may be indicated. ■ **Other strong inducers of hepatic enzymes** (e.g., carbamazepine, phenytoin, phenobarbital) may cause a decrease in linezolid concentration. ■ Severe myelosuppression may occur with **bone marrow suppressants and other drugs that affect platelet function;** see Monitor.

SIDE EFFECTS

The most common side effects are anemia, diarrhea, headache, nausea, and vomiting. Other reported side effects include abdominal pain; CDAD; constipation; dizziness; dysgeusia (change in sense of taste); dyspepsia; eosinophilia; fever; fungal infection; hypertension; increased AST, BUN, SCr, total bilirubin; insomnia; lactic acidosis; myelosuppression (anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia); neuropathy (peripheral and optic [optic neuropathy may progress to vision loss]); oral moniliasis; pruritus; rash; seizures; serotonin syndrome (cognitive dysfunction, hyperpyrexia, hyperreflexia, lack of coordination); tongue discoloration; vaginal moniliasis; vertigo; and vomiting.

Post-Marketing:

Anaphylaxis; angioedema; bullous skin disorders, including severe cutaneous adverse reactions (SCAR) such as toxic epidermal necrolysis and Stevens-Johnson syndrome; convulsions; hypoglycemia (including symptomatic episodes); sideroblastic anemia; and superficial tooth and tongue discoloration.

ANTIDOTE

Keep physician informed of all side effects. Discontinue drug if indicated. If S/S of serotonin syndrome develop, consider discontinuing linezolid or the serotonergic agent. Consider discontinuing linezolid in patients who develop or have worsening myelosuppression. Mild cases of CDAD may respond to discontinuation of linezolid. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. In the event of an overdose, initiate supportive care and maintain glomerular filtration. Both linezolid and its metabolites are partially removed by hemodialysis.

LIOTHYRONINE SODIUM BBW

(lye-oh-**THIGH**-roh-neen **SO**-dee-um)
T_3, Triostat
Hormone (thyroid)
pH 9.5 to 11.5

USUAL DOSE

Pretreatment:

Testing and adjunctive therapy with corticosteroids required; see Monitor.

Initial and subsequent doses must be determined on the basis of continuous monitoring of clinical condition and response to liothyronine therapy. An adequate dose is important in determining clinical outcome.

Myxedema coma:

25 to 50 mcg as an initial dose. At least 4 hours but no more than 12 hours should elapse between doses; allows sufficient time to evaluate response and avoids fluctuation in hormone levels. Myxedematous patients have an increased sensitivity to thyroid hormones. Begin with lower doses and increase gradually. Use caution in adjusting dose to avoid large changes that may precipitate adverse cardiovascular events. A total daily dose of 65 mcg/day in the initial days of treatment has decreased mortality. Experience with doses above 100 mcg/day is limited.

Transfer to oral therapy:

Initiate oral therapy as soon as condition is stabilized and patient is able to take oral medications. With oral liothyronine, discontinue IV liothyronine and begin with low doses. Increase gradually based on response. If levothyroxine (L-thyroxine, T_4) is used, discontinue IV therapy gradually to compensate for several-day delay in effectiveness of oral levothyroxine.

DOSE ADJUSTMENTS

Reduce initial dose to 10 to 20 mcg in known or suspected cardiovascular disease. ■ Begin with lower doses in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. Available as 10 mcg/mL in 1-mL vials.

Storage:

Must be refrigerated until administration. Discard unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 10 mcg or fraction thereof over 1 minute.

ACTIONS

A synthetic form of the natural thyroid hormone triiodothyronine (T_3). Enters peripheral tissues readily and binds to specific nuclear receptor(s) to initiate hormonal, metabolic effects. Affinity for these receptors is 10-fold higher than prohormone T_4

(levothyroxine) and no additional conversion (T_4 to T_3) is required. Increases metabolic rate and reverses the loss of consciousness, hypothermia, lactic acidosis, and other symptoms of myxedema coma. Thyroid hormones have many beneficial effects on general metabolism and the cardiovascular system. Liothyronine produces a detectable metabolic response in 2 to 4 hours. Achieves maximum therapeutic response within 48 hours. Has a rapid cutoff of activity, permitting quick dose adjustments and/or control of overdose. Metabolized in the liver to an inactive metabolite. Does not readily cross the placental barrier. Minimal secretion in breast milk.

INDICATIONS AND USES

Treatment of myxedema coma and precoma (patient not completely unconscious). ■ May be used in patients allergic to desiccated thyroid or thyroid extract derived from pork or beef.

CONTRAINDICATIONS

Concomitant use with artificial patient rewarming; generally contraindicated in diagnosed but uncorrected adrenal cortical insufficiency or untreated thyroxicosis; hypersensitivity to any components (no documented evidence of true hypersensitivity idiosyncratic reactions). Not indicated for use in treatment of obesity or male or female infertility without hypothyroidism. Risk can outweigh benefit.

PRECAUTIONS

For IV use only. ■ Myxedema coma is a medical emergency usually precipitated in a hypothyroid patient by illness, sedatives, or anesthetics. Has a 50% to 70% mortality rate even with aggressive therapy. ■ Use with caution in presence of any compromised cardiac function or cardiac disease, particularly of the coronary arteries. ■ May precipitate a hyperthyroid state or may aggravate existing hyperthyroidism. ■ Due to the rarity of myxedema coma and precoma, no systematic studies have been performed with IV liothyronine.

Monitor:

Confirm diagnosis with serum TSH (greater than 60 mcU/mL), serum total T_4 and free T_4 (low), and serum total T_3 and free T_3 (normal or low). Repeat as indicated to evaluate response to treatment. ■ ECG, chest x-ray, CBC, AST, CPK, LDH, lipids, serum electrolytes, serum cortisol, cerebrospinal fluid examination, and EEG are helpful before dose administration. Monitor progress by repeat evaluations at selected intervals. ■ Correct adrenocortical insufficiency before administration or acute adrenal crisis and death may result. Corticosteroids (e.g., dexamethasone, methylprednisolone) should be administered routinely in the initial emergency treatment of all myxedema coma patients; required before starting liothyronine or simultaneously with administration in pituitary myxedema; recommended in primary myxedema. During therapy metabolism increases at a greater rate than adrenocortical activity; can precipitate adrenocortical insufficiency and shock; corticosteroids may be needed throughout therapy. ■ In any patient with compromised cardiac function, monitoring of cardiac function is required. ■ Assisted or artificial ventilation may be required. ■ Treatment should correct electrolyte disturbances, possible infection, or other illness. ■ IV fluids will be required, but use caution to prevent cardiac decompensation and be alert for water intoxication from inappropriate secretion of ADH. ■ Do not rewarm patient artificially; may further decrease circulation to vital internal organs and increase shock. Normal body temperature can be restored in 24 to 48 hours by preventing heat loss. Keep patient covered with blankets in a warm room. ■ See Drug/Lab Interactions.

Maternal/Child:

Category A: clinical experience does not indicate adverse effect on fetus. ■ Observe infant carefully for any adverse symptoms if breast-feeding; minimal amounts secreted in breast milk. ■ Experience with pediatric patients under 18 years of age is limited; safety and effectiveness not established.

Elderly:

Response similar to other age-groups; however, may be more sensitive to effects. Evaluate carefully for any occult cardiac disease; see Precautions/Monitor. ■ Reduced dose may be indicated; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Metabolic requirements are markedly reduced in hypothyroid patients. Concomitant use with **vasopressors** (e.g., epinephrine, dopamine) may increase risk of coronary insufficiency, arrhythmias, or circulatory collapse. Use lower doses and extreme caution. ■ Observe any patient previously stabilized on **anticoagulants** carefully; dose reduction may be required. Monitor PT. ■ Increased doses of **insulin or oral hypoglycemics** may be required. ■ Higher doses of levothyroxine may be required with **estrogens or estrogen-containing oral contraceptives** in the patient with a nonfunctioning thyroid. ■ May cause transient cardiac arrhythmias with **tricyclic antidepressants** (e.g., imipramine [Tofranil]). ■ May potentiate toxic effects of **digoxin,** whereas increased metabolism may require a higher digoxin dose. ■ Hypertension and tachycardia are probable with **ketamine anesthesia.** Be prepared to treat promptly. ■ Pregnancy, as well as many drugs (e.g., androgens, corticosteroids, estrogens, estrogen oral contraceptives, iodine preparations, salicylates) in combination with thyroid preparations, **interfere with accurate interpretation of lab tests.** Consult with lab personnel.

SIDE EFFECTS

Average dose:

Arrhythmia (6%), cardiopulmonary arrest (2%), hypotension (2%), myocardial infarction (2%), tachycardia (3%). Angina, congestive heart failure, fever, hypertension, phlebitis, and twitching occurred in 1% or less.

Overdose:

Acute myocardial infarction, angina pectoris, arrhythmia, congestive heart failure, headache, increased bowel motility, irritability, menstrual irregularities, nervousness, shock, sweating, tachycardia, thyroid storm, tremor.

ANTIDOTE

Keep physician informed of all side effects. If side effects progress or overdose occurs, reduce or temporarily discontinue liothyronine. Restart at lower doses when feasible. Treatment is symptomatic and supportive. Oxygen and artificial ventilation may be required. Treat increased sympathetic activity with beta-adrenergic antagonists (e.g., esmolol [Brevibloc]). Monitor fever, hypoglycemia, and fluid loss and treat as needed. Digoxin (Lanoxin) may be required in congestive heart failure.

LORAZEPAM BBW

(lor-**AYZ**-eh-pam)
Ativan, Lorazepam PF
Benzodiazepine
Sedative-hypnotic
Antianxiety agent
Anticonvulsant

USUAL DOSE

Pretreatment:

Verify pregnancy status; see Maternal/Child.

Dose must be individualized, especially when used in conjunction with other medications that may cause CNS depression. See Dose Adjustments, Precautions, and Drug/Lab Interactions.

Preoperative sedation/antianxiety/amnestic:

2 mg or 0.044 mg/kg of body weight, whichever is smaller, 15 to 20 minutes before procedure. For greater lack of recall 0.05 mg/kg up to 4 mg may be given. 2 mg is usually the maximum dose for patients over 50 years of age.

Sedation in intubated and mechanically ventilated ICU patients (unlabeled):

0.02 to 0.04 mg/kg (maximum single dose: 2 mg). Follow with a maintenance dose of 0.02 to 0.06 mg/kg every 2 to 6 hours as needed or with an infusion of 0.01 to 0.1 mg/kg/hr. Titrate to achieve adequate sedation. Up to 5 to 10 mg/hr has been used. When sedation is adequate, reduce to lowest amount needed.

Status epilepticus:

4 mg as the initial dose. May repeat once in 10 to 15 minutes if seizures continue or recur. Experience with further doses is very limited. Additional intervention (e.g., concomitant administration of phenytoin) may be required. Another source suggests 0.1 mg/kg of body weight to a total dose of 4 mg. May repeat once in 5 to 10 minutes. If still not effective, use another anticonvulsant agent (e.g., phenytoin).

Management of emetic-inducing chemotherapy (unlabeled):

One source recommends 0.5 to 2 mg every 6 hours as needed. Another source suggests 1.5 mg/M^2 (up to a maximum of 3 mg) over 5 minutes. Administer 30 to 45 minutes before administration of antineoplastic agent. May be given in combination with other antiemetics (e.g., ondansetron [Zofran], dexamethasone).

PEDIATRIC DOSE

Safety for use in pediatric patients under 12 years of age has not been fully studied, but it has been used for status epilepticus in neonates, infants, and children; see Maternal/Child.

Sedation in intubated and mechanically ventilated pediatric ICU patients (unlabeled):

0.025 to 0.05 mg/kg/dose up to a maximum of 2 mg/dose every 2 to 4 hours or as an infusion at a rate of 0.025 mg/kg/hr (up to 2 mg/hr). Titrate to effect.

Status epilepticus (unlabeled; see Maternal/Child):

Neonates, infants, and children:

0.05 to 0.1 mg/kg up to a maximum of 4 mg/dose. Another source suggests a maximum dose of 2 mg/dose. May repeat 0.05 mg/kg once in 10 to 15 minutes if needed.

Antiemetic, adjunct therapy (unlabeled):

0.02 to 0.05 mg/kg/dose up to a maximum of 2 mg/dose. May repeat every 6 hours as needed.

DOSE ADJUSTMENTS

Start with a small dose in the elderly and increase gradually based on response. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Dose adjustments are not required with impaired liver function. ■ Dose adjustments are not required with impaired renal function unless frequent doses are given over a short period of time. ■ Reduced dose may be indicated in the presence of other CNS depressants. ■ Reduce dose by 50% when given concurrently with probenecid or valproate. ■ See Drug/Lab Interactions.

DILUTION

IV injection:

Dilute immediately before use with an equal volume of SWFI, D5W, or NS. Do not shake vigorously; will result in air entrapment. Gently invert repeatedly until completely in solution. May be given by IV injection or through Y-tube or three-way stopcock of infusion tubing.

Infusion (unlabeled):

One source recommends further diluting the 2-mg/mL concentration in a non-PVC (glass or polyolefin) container to a concentration of 1 mg/mL or less using D5W or NS.

Alternatively, the 2-mg/mL concentration has been administered undiluted as an infusion using a patient-controlled analgesia infusion pump.

Very viscous; mix well and observe for crystallization. Crystallization does occur and is thought to be due to propylene glycol preservative. May occur more frequently with 4-mg/mL vials of lorazepam base than with 2-mg/mL vials.

Filter:

Use of an in-line filter is required with administration of an infusion (unlabeled).

Storage:

Refrigerate before dilution; protect from light. Use only freshly prepared solutions; discard if discolored or precipitate forms. Infusions stable at room temperature for 24 hours in glass.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 2 mg or fraction thereof over 1 to 5 minutes.

Infusion:

Use a microdrip or infusion pump for accuracy to deliver desired dose and/or titrate to desired level of sedation.

Pediatric rate:

2 mg/min is the maximum rate of administration.

ACTIONS

A benzodiazepine with antianxiety, sedative, and anticonvulsant effects. Inhibits ability to recall events. Interacts with the GABA-benzodiazepine receptor complex in the brain. Effective in 15 to 20 minutes. Effects last an average of 6 to 8 hours but may last as long as 12 to 24 hours. Half-life is 9 to 19 hours. Metabolized by the liver to inactive metabolites; excreted in urine and to a lesser extent in the feces. Crosses the placental barrier. Excreted in breast milk.

INDICATIONS AND USES

Preanesthetic medication for adult patients. Produces sedation, relieves anxiety, and provides anterograde amnesia. ■ Management of status epilepticus.

Unlabeled uses:

Chemotherapy-associated nausea and vomiting (adjunct, breakthrough, or anticipatory). ■ Treatment of alcohol withdrawal. ■ Amnestic during endoscopic procedures.

CONTRAINDICATIONS

Hypersensitivity to benzodiazepines or the components (e.g., polyethylene glycol, propylene glycol, or benzyl alcohol). ■ Patients with acute narrow-angle glaucoma, sleep apnea syndrome, or severe respiratory insufficiency (except patients requiring relief of anxiety and/or diminished recall of events while being mechanically ventilated). ■ Intra-arterial injection. ■ Use in premature infants because the formulation contains benzyl alcohol.

PRECAUTIONS

Rapidly and completely absorbed IM. ■ When given as a sedative, patient is able to respond to simple instructions. ■ Increased risk of airway obstruction and respiratory depression; airway support, emergency drugs, and equipment must be immediately available. ■ Dependence is possible with prolonged use or high dose. ■ Use with extreme caution in the elderly, the very ill, or patients with limited pulmonary reserve; risk of hypoventilation and/or hypoxic cardiac arrest is increased. ■ Use as a premedicant before local or regional anesthesia may cause excessive drowsiness and interfere with assessment of levels of anesthesia. More likely to occur with doses greater than 0.05 mg/kg or when narcotic agents are used concomitantly. ■ Use with caution in patients with mild to moderate renal or hepatic disease. Not recommended for use in patients with hepatic and/or renal failure. ■ There have been reports of possible propylene and polyethylene glycol toxicity (e.g., lactic acidosis, hyperosmolality, hypotension, acute tubular necrosis) when lorazepam has been administered at higher than recommended doses. Patients with renal impairment may be at increased risk of developing toxicity. ■ Paradoxical reactions may occur. ■ There are insufficient data to support the use of lorazepam injection for outpatient endoscopic procedures. Inpatient endoscopic procedures require adequate recovery room observation time. ■ When lorazepam is used for peroral endoscopic procedures, adequate topical or regional anesthesia is recommended to minimize the reflex activity associated with such procedures. ■ See Antidote (e.g., risk of seizure with flumazenil).

Monitor:

To reduce incidence of thrombophlebitis, avoid smaller veins. Extravasation is hazardous; arterial administration may cause arteriospasms and gangrene and/or require amputation. ■ Monitor patients for respiratory depression and sedation, especially when used concomitantly with opioids and other CNS depressants; see Drug/Lab Interactions. ■ Monitor and maintain patent airway. Respiratory assistance and flumazenil must be available. ■ Monitor vital signs. ■ Monitor depth of sedation in critically ill patients (e.g., Richmond Agitation-Sedation Scale [RASS]). ■ Contains propylene glycol. Monitor for toxicity if administered as a continuous infusion (e.g., acute renal failure, lactic acidosis, and/or osmol gap). ■ ***Status epilepticus:*** Establish an IV and monitor vital signs. In addition to the above, observe for and correct any other possible cause of seizure (e.g., hypoglycemia, hyponatremia, other metabolic disorders). ■ Sedative effects may add to the impairment of consciousness seen in the post-ictal state (e.g., after a seizure). ■ Neurologic consult is suggested for any patient who fails to regain consciousness.

Patient Education:

May produce drowsiness or dizziness; request assistance with ambulation and use caution when performing tasks that require alertness for 24 to 48 hours or until the effects of the drug have subsided. ■ Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates) for 24 to 48 hours or until the effects of the drug have subsided. ■ Has amnestic potential; may impair memory. ■ Discuss with parents or caregivers the risks, benefits, timing, and duration of surgery or procedures requiring anesthetic and sedation drugs; see Maternal/Child.

Maternal/Child:

Category D: avoid pregnancy. May cause fetal harm. Not recommended during pregnancy except in serious or life-threatening conditions in which safer drugs cannot be used or are ineffective. Status epilepticus may represent a serious and life-threatening condition. Not recommended for use in labor and delivery, breast-feeding, or in pediatric patients under 12 years of age. ■ Has FDA approval for treatment of status epilepticus in adults over 18 years of age. Safety and effectiveness for use in status epilepticus have not been established in pediatric patients. A randomized, double-blind, superiority-designed clinical trial of lorazepam versus diazepam failed to establish the efficacy of lorazepam for this indication. ■ There are insufficient data to support the efficacy of injectable lorazepam as a preanesthetic agent in patients under 18 years of age. ■ May cause paradoxical excitement in pediatric patients. ■ Seizure activity and myoclonus have been reported in low-birth-weight neonates. ■ Published studies suggest that repeated or prolonged exposures to certain anesthetic and sedation agents in utero (third trimester) and early in life (up to 3 years of age) may have negative effects on the developing brain, resulting in adverse cognitive or behavioral effects; see prescribing information for further discussion. Balance the benefits of appropriate anesthesia/sedation in pregnant women, neonates, and young children who require procedures with the potential risks described. ■ Contains benzyl alcohol. Exposure to excessive amounts of benzyl alcohol has been associated with toxicity (hypotension, metabolic acidosis), particularly in neonates, and an increased incidence of kernicterus, particularly in preterm infants. There have been rare reports of death; see Contraindications. ■ Half-life prolonged in pediatric patients.

Elderly:

Dosing should be cautious in the elderly; see Dose Adjustments. ■ More sensitive to therapeutic and adverse effects (e.g., ataxia, central nervous system depression, dizziness, oversedation, respiratory depression). ■ See Precautions and Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

Concomitant use of **benzodiazepines and opioids** (e.g., morphine, meperidine, fentanyl) may result in profound sedation, respiratory depression, coma, and death. If used concomitantly with opioids, monitor patients closely for respiratory depression and sedation. ■ Concurrent use with **other CNS depressants** such as alcohol, antihistamines, barbiturates, MAO inhibitors, phenothiazines, and tricyclic antidepressants may result in additive effects for up to 48 hours. Reduced dose may be indicated. Monitor for S/S of respiratory depression and sedation. ■ Concurrent administration with **valproate or probenecid** will decrease clearance of lorazepam. Reduce dose of lorazepam by one-half in patients receiving concurrent valproate or probenecid. ■ Apnea, arrhythmia, bradycardia, cardiac arrest, coma, and death have been reported when used concurrently with **haloperidol**. ■ May increase serum concentrations of **digoxin and phenytoin**; monitor digoxin and phenytoin serum levels. ■ **Theophyllines** (aminophylline) antagonize the sedative effects of benzodiazepines. ■ Marked sedation, excessive salivation, ataxia and, rarely, death have been reported with concomitant use of **clozapine** and lorazepam. ■ Estrogen-containing **oral contraceptives** increase clearance and decrease the effects of lorazepam. ■ Inhibits antiparkinson effectiveness of **levodopa.** ■ Incidence of hallucinations and irrational behavior and an increased incidence of sedation have been observed with concurrent use of scopolamine.

SIDE EFFECTS

Airway obstruction, apnea, blurred vision, central nervous system depression (e.g., drowsiness, excessive sleepiness), confusion, crying, delirium, depression, hallucinations, headache, hypotension, hypoventilation, injection site reaction, paradoxical reactions, respiratory depression/failure, restlessness, somnolence, stupor.

Overdose:

Ataxia, coma, hypnosis, hypotension, hypotonia and, very rarely, death.

ANTIDOTE

Notify physician of all symptoms. Reduction of dose may be required. Treat hypotension with dopamine or norepinephrine. In overdose, flumazenil will reverse all sedative effects of benzodiazepines. See flumazenil monograph (risk of seizures). A patent airway, artificial ventilation, oxygen therapy, and other symptomatic and supportive treatment must be instituted promptly. Monitor vital signs and fluid status carefully. Forced diuresis and osmotic diuretics (e.g., mannitol) may increase rate of lorazepam elimination. The value of dialysis has not been adequately determined.

LURBINECTEDIN

(**LOOR**-bin-**EK**-te-din)
Zepzelca
Antineoplastic agent
Alkylating agent

USUAL DOSE

3.2 mg/M^2/dose IV every 21 days until disease progression or unacceptable toxicity; initiate therapy only if ANC is 1500/mm^3 or greater and platelets are 100,000/mm^3 or greater.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

Grade 2 hepatoxicity during treatment:

Withhold until improved to Grade 1 or less, then resume at same dose.

Grade 3 hepatotoxicity during treatment:

Withhold until improved to Grade 1 or less, then resume at reduced dose.

DILUTION

Reconstitute each vial with 8 mL of SWFI to a concentration of 0.5 mg/mL. Shake the vial until completely dissolved. Withdraw prescribed dose from vial and add to infusion container of at least 100 mL if given through central line or at least 250 mL if given through peripheral line of NS or D5W.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS or D5W.

RATE OF ADMINISTRATION

Administer as an IV infusion over 60 minutes.

ACTIONS

Lurbinectedin is an alkylating drug and a selective inhibitor of oncogenic transcription, which results in tumor cell apoptosis.

INDICATIONS AND USES

Metastatic small-cell lung cancer.

CONTRAINDICATIONS

No contraindications listed by manufacturer.

PRECAUTIONS

Bone marrow suppression and hepatotoxicity can occur.

Monitor:

Blood counts and LFTs must be done prior to each cycle and then periodically during treatment and as clinically necessary.

Patient Education:

Advise patients to call physician if they experience infection, vomiting blood (coffee ground emesis), liver problems (dark urine, lack of appetite, abdominal pain, yellow skin), high blood sugar (confusion, increased thirst, hunger, frequent urination, fruity-smelling breath), electrolyte problems (mood changes, confusion, muscle weakness or pain, irregular heartbeat, vomiting), shortness of breath, numbness, not passing urine.

Maternal/Child:

Check pregnancy status prior to use. Advise patient to use effective contraception during therapy and at least 6 months after last dose. May cause fetal harm. Breast-feeding is not recommended.

Elderly:

Refer to Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

5-ASA, bacille Calmette-Guérin (BCG) vaccine, baricitnib, brincidofovir, chloramphenicol ophthalmic, cladribine, clozapine, COVID-19 vaccines (may decrease effectiveness), moderate and strong CYP3A4 inducers (may decrease effectiveness of lurbinectedin; avoid), strong CYP3A4 inhibitors (may increase serum concentration of lurbinectedin; avoid), deferiprone, denosumab, dipyrone, Echinacea, fexinidazole, fingolimod, inebilzumab, leflunomide, MMR vaccine (avoid), natalizumab, ocrelizumab, ofatumumab, ozanimod, pidotimod, pimecrolimus (avoid), ponesimod, promazine, rabies vaccine, siponimod, sipuleucel-T, smallpox and monkey pox vaccine, tacrolimus topical (avoid), talimogene laherparepvec (avoid), tofacitinib, upadacitinib (avoid), live vaccines (avoid), varicella virus vaccine (avoid). Inactivated vaccines may have reduced response; give prior to therapy start. Please refer to package insert for further information.

SIDE EFFECTS

Abdominal pain; anorexia; chest pain; constipation; cough; decreased serum albumin, magnesium, sodium; diarrhea; dyspnea; fatigue; febrile neutropenia; headache; increased ALT and AST enzymes; increased serum creatinine; increased serum glucose; muscle pain; nausea; peripheral neuropathy; pneumonia; respiratory tract infection; sepsis; vomiting.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

LYMPHOCYTE IMMUNE GLOBULIN BBW

(**LIM**-foh-sight ih-**MUNE GLAW**-byoo-lin)
Anti-Thymocyte Globulin [Equine], Atgam
Immunosuppressant
pH 6.8

USUAL DOSE

Pretreatment:

Intradermal skin test required before administration.

Use 0.1 mL of a 1:1,000 dilution in NS and a saline control. If a systemic reaction (rash, dyspnea) occurs, do not administer. If a limited reaction (10-mm wheal or erythema) occurs, proceed with extreme caution. Anaphylaxis can occur even if skin test is negative.

Range is 10 to 30 mg/kg of body weight/24 hr. Actual potency and activity may vary from lot to lot. Given concomitantly with other immunosuppressive therapy (antimetabolites such as azathioprine and corticosteroids).

Delay onset of renal allograft rejection:

15 mg/kg/24 hr for 14 days, then every other day for 7 more doses. Initial dose should be given 24 hours before or after the transplant.

Treat allograft rejection:

10 to 15 mg/kg/24 hr for 14 days, then every other day for 7 more doses (optional). Initial dose should be given when first rejection episode is diagnosed.

Aplastic anemia:

10 to 20 mg/kg/24 hr for 8 to 14 days. Additional alternate-day therapy up to a total of 21 doses may be given.

PEDIATRIC DOSE

Experience with pediatric patients is limited and unlabeled. Intradermal skin test required; see Usual Dose. Has been administered to treat aplastic anemia, to manage renal allograft rejection, and to delay onset of renal allograft rejection using mg/kg doses recommended for adults.

DILUTION

Total daily dose must be further diluted with NS, D5/¼NS, or D5/½NS for infusion. Invert solution while injecting drug so contact is not made with air in infusion bottle. Gently rotate diluted solution. Do not shake. Concentration should not exceed 4 mg/mL. May be infused into a vascular shunt, AV fistula, or high-flow central vein.

Filters:

Use of a 0.2- to 1-micron filter recommended.

Storage:

Keep refrigerated before and after dilution. Discard diluted solution after 24 hours.

COMPATIBILITY

Manufacturer states lymphocyte immune globulin may precipitate in dextrose solutions and may be unstable with highly acidic solutions.

RATE OF ADMINISTRATION

A total daily dose equally distributed over a minimum of 4 hours.

ACTIONS

A lymphocyte-selective immunosuppressant. Reduces the number of thymus-dependent lymphocytes and contains low concentrations of antibodies against other formed elements in blood. Effective without causing severe lymphopenia. Supports an increase in the frequency of resolution of an acute rejection episode. Has a serum half-life of 5 to 8 days.

INDICATIONS AND USES

Management of allograft rejection in renal transplant patients. ■ Adjunctive to other immunosuppressive therapy to delay onset of initial rejection episode. ■ Treatment of moderate to severe aplastic anemia in patients who are not candidates for bone marrow transplant.

CONTRAINDICATIONS

Systemic hypersensitivity reaction to previous injection of lymphocyte immune globulin or any other equine gamma-globulin preparation.

PRECAUTIONS

Administered only under the direction of a physician experienced in immunosuppressive therapy and management of renal transplant patients in a facility with adequate laboratory and supportive medical resources. ■ Use caution in repeated courses of therapy; observe for signs of hypersensitivity reactions.

Monitor:

Will cause chemical phlebitis in peripheral veins. ■ Monitor carefully for signs of infection, leukopenia, or thrombocytopenia. Thrombocytopenia is usually transient in renal transplant patients. Platelet transfusions may be necessary in patients with aplastic anemia. Notify physician immediately so prompt treatment can be instituted and/or drug discontinued. ■ Prophylactic antibiotics may be indicated pending results of C/S. ■ Masked reactions may occur as dose of corticosteroids and antimetabolites is decreased. Observe carefully. ■ Antihistamines (e.g., diphenhydramine) may be required to control itching. ■ Anaphylaxis can occur at any time. Monitor closely for S/S of a hypersensitivity reaction. Emergency equipment and supplies must be at bedside.

Patient Education:

See Appendix D, p. 1311.

Maternal/Child:

Category C: no studies conducted in pregnant patients. Use caution. ■ Safety for use in breast-feeding not established. ■ Limited experience on use in pediatric patients; see Pediatric Dose.

DRUG/LAB INTERACTIONS

See Monitor.

SIDE EFFECTS

Full range of hypersensitivity reactions, including anaphylaxis, is possible. Arthralgia, back pain, chest pain, chills, clotted AV fistula, diarrhea, dyspnea, fever, headache, hypotension, infusion site pain, leukopenia, nausea, night sweats, pruritus, rash, stomatitis, thrombocytopenia, thrombophlebitis, urticaria, vomiting, wheal and flare. Other reactions occur in fewer than 1% of patients.

ANTIDOTE

Notify physician of all side effects. Discontinue if anaphylaxis, severe and unremitting thrombocytopenia, and/or severe and unremitting leukopenia occur; see Monitor. May be discontinued if infection or hemolysis present even if appropriately treated. Clinically significant hemolysis may require erythrocyte transfusion, IV mannitol, furosemide, sodium bicarbonate, and fluids. Prophylactic or therapeutic antihistamines (e.g., diphenhydramine) or corticosteroids should control chills caused by release of endogenous leukocyte pyrogens. Treat anaphylaxis immediately. Epinephrine, diphenhydramine, oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

USUAL DOSE

Individualize dose based on patient requirement and response. Discontinue as soon as desired response is obtained. Doses are expressed as magnesium sulfate unless stated otherwise. 1 Gm of magnesium sulfate = 98.6 mg elemental magnesium = 8.12 mEq of elemental magnesium.

Pre-eclampsia and eclampsia:

Several regimens in literature. The recommended loading dose is 4 to 6 Gm over 15 minutes followed by a recommended maintenance dose of 1 to 2 Gm/hr. For patients with eclampsia, therapy should continue until seizures cease. Consider giving an additional 2-Gm dose for patients with recurrent eclampsia.

Another regimen suggests a total initial dose of 10 to 14 Gm. This may be achieved by administering 4 to 5 Gm in 250 mL of D5W or NS IV. Simultaneously, IM doses of up to 10 Gm (5 Gm or 10 mL of the undiluted 50% solution in each buttock) are given. Alternatively, the initial IV dose of 4 Gm may be given by diluting the 50% solution to a 10% or 20% concentration that is injected over 3 to 4 minutes. Subsequent 4- to 5-Gm doses may be given IM every 4 hours as needed, or a continuous infusion of 1 to 2 Gm/hr may be initiated.

Do not exceed 30 to 40 Gm/24 hr. Frequent monitoring required; see Dose Adjustments, Precautions, and Monitor.

Seizures associated with epilepsy, glomerulonephritis, or hypothyroidism:

1 Gm IV.

Hypomagnesemia (mild):

1 Gm IM every 6 hours for 4 doses. Another source recommends 1 to 4 Gm administered IV at a rate of 1 Gm/hr or less.

Hypomagnesemia (severe):

5 Gm (40 mEq) in 1,000 mL D5W or NS as an infusion evenly distributed over 3 hours. Another source recommends 4 to 8 Gm IV administered at a rate of 1 Gm/hr or less for asymptomatic patients. If symptomatic, may administer a dose of 4 Gm or less over 4 to 5 minutes.

Parenteral nutrition in adults:

8 to 24 mEq/24 hr IV (1 to 3 Gm).

Paroxysmal atrial tachycardia (unlabeled):

3 to 4 Gm IV (30 to 40 mL of a 10% solution) over 30 seconds with extreme caution. Reserve for patients in whom simpler measures have failed and in whom there is no evidence of myocardial damage.

Reduction of cerebral edema (unlabeled):

2.5 Gm IV (25 mL of a 10% solution).

Cardiac arrest (hypomagnesemia or torsades de pointes):

AHA recommends 1 to 2 Gm (2 to 4 mL of a 50% solution) diluted in 10 mL D5W as a bolus.

Torsades de pointes:

AHA recommends a loading dose of 1 to 2 Gm in 50 to 100 mL D5W as an infusion over 5 to 60 minutes. May follow with an infusion of 0.5 to 1 Gm/hr and titrate to control the torsades.

Barium poisoning:

1 to 2 Gm IV.

Alleviate bronchospasm in acute asthma (unlabeled):

2 Gm given IV over 20 minutes. Usually given concurrently with inhaled albuterol (Proventil) and IV corticosteroids.

PEDIATRIC DOSE

All pediatric doses are unlabeled; see Maternal/Child.

Hypomagnesemia:

25 to 50 mg/kg of body weight/dose. May repeat at 6-hour intervals for 2 to 3 doses, then recheck serum magnesium. Maximum recommended single dose is 2 Gm.

Pulseless VT with torsades de pointes:

AHA recommends 25 to 50 mg/kg/dose IV push. A 50% solution equals 500 mg/mL. Maximum recommended dose is 2 Gm.

Status asthmaticus:

25 to 75 mg/kg as an infusion over 20 minutes. Maximum recommended dose is 2 Gm.

Parenteral nutrition:

0.3 to 0.5 mEq/kg/day (dose expressed as elemental magnesium).

DOSE ADJUSTMENTS

Reduce dose of other CNS depressants (e.g., narcotics, barbiturates) when given in conjunction with magnesium sulfate. ■ Reduce dose in impaired renal function and in the elderly. ■ In patients with severe renal impairment and/or a urine output less than 0.5 mL/kg/hr, initiate prevention or treatment of eclampsia with a loading dose of 4 Gm in D5W followed by a maintenance infusion of 1 Gm/hr. Titrate to maintain the concentration in the target range and monitor closely for S/S of magnesium toxicity. A lower maintenance dose requirement is likely in these patients. Do not exceed the maximum recommended dose of 20 Gm of magnesium sulfate over 48 hours. ■ Reduce dose by 50% in patients with renal dysfunction being treated for hypomagnesemia; close monitoring is required.

DILUTION

Concentrated solutions must be diluted to a concentration of 20% (200 mg/mL) or less for IV administration. D5W and NS are the most common diluents. Available in various containers in multiple concentrations and also in multiple concentrations as a premixed solution in sterile water for injection or in 5% dextrose. See Usual Dose for specific dilutions. May be given through Y-tube or three-way stopcock of infusion set.

Storage:

Store at CRT. Protect from freezing. Contains no preservative. Discard any unused solution.

COMPATIBILITY

Will form various precipitates with alcohol (in high concentrations), alkali carbonates and bicarbonates, alkali hydroxides, arsenates, barium, calcium, clindamycin, heavy metals, hydrocortisone sodium succinate, phosphates, salicylates, strontium, and tartrates. Use caution; consult pharmacist.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

150 mg (1.5 mL of a 10% solution or its equivalent) over at least 1 minute, must be diluted first, or as directed in Usual Dose.

IV infusion:

As directed in Usual Dose.

ACTIONS

An important cofactor for enzymatic reactions and plays an important role in neurochemical transmission and muscular excitability. It prevents or controls seizures by blocking neuromuscular transmission and decreasing the amount of acetylcholine release. Acts peripherally to produce vasodilation and may cause a lowering of BP at higher doses. Has a depressant effect on the CNS but does not adversely affect the woman, fetus, or neonate when used as directed in eclampsia or pre-eclampsia. Onset of anticonvulsant action is immediate and lasts for about 30 minutes. Average half-life in women with pre-eclampsia is approximately 4 to 5 hours. Excreted in the urine. Secreted in breast milk. Crosses the placental barrier.

INDICATIONS AND USES

Replacement therapy in magnesium deficiency (e.g., acute hypomagnesemia accompanied by signs of tetany similar to those seen in hypocalcemia). ■ Correction or prevention of hypomagnesemia in patients receiving TPN. ■ Prevention and control of seizures in pre-eclampsia and eclampsia, respectively.

Unlabeled uses:

Control of seizures associated with epilepsy, glomerulonephritis, hypothyroidism. ■ Reduction of cerebral edema. ■ Acute nephritis in pediatric patients to control hypertension, encephalopathy, and convulsions. ■ Treatment of torsades de pointes, ventricular tachycardia, and ventricular fibrillation (VT/VF) caused by hypomagnesemia. ■ Counteract muscle-stimulating effects of barium poisoning. ■ Treatment of paroxysmal atrial tachycardia. ■ Treatment of acute asthma in patients who do not respond to conventional therapy.

CONTRAINDICATIONS

Presence of heart block or myocardial damage. ■ Diabetic coma. ■ Myasthenia gravis.

PRECAUTIONS

Continuous administration of magnesium sulfate beyond 5 to 7 days to pregnant women can lead to hypocalcemia and bone abnormalities in the developing fetus, including skeletal demineralization, osteopenia, and neonatal fracture. ■ Patients receiving magnesium sulfate are at risk for magnesium toxicity, including respiratory depression, acute renal failure and, rarely, pulmonary edema. ■ Use caution in impaired renal function; may result in magnesium toxicity. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. Tissue loading may occur at even lower rates of administration. ■ Administer with caution if flushing and sweating occur (first signs of vasodilation). ■ Solutions containing dextrose should be used with caution in patients with known prediabetes or diabetes mellitus given the risk of elevated blood glucose. ■ Use of magnesium sulfate in patients with underlying myasthenia gravis can precipitate a myasthenic crisis; see Contraindications. ■ See Drug/Lab Interactions.

Monitor:

Discontinue IV administration when the desired therapeutic effect is obtained. ■ Monitor for clinical signs of magnesium toxicity (e.g., facial edema, diminished strength of deep tendon reflexes, respiratory depression). ■ Monitor magnesium levels. Normal plasma magnesium levels range from 1.5 to 2.5 mEq/L. Consider targeting maintenance dose to achieve serum magnesium concentrations of 2.5 to 5 mEq/L (3 to 6 mg/100 mL) in patients with eclampsia. Deep tendon reflexes decrease at plasma magnesium levels above 4 mEq/L and disappear as levels approach 10 mEq/L. Respiratory paralysis will occur at this level. ■ With each repeated dose, test patellar reflex (knee jerks) and observe respirations. If the knee jerk is absent or if respirations are less than 16/min, ***do not*** give additional magnesium sulfate. ■ Equipment to maintain artificial ventilation must be available at all times. Patient must be continuously observed. ■ Maintain minimum of 100 mL of urine or more during the 4 hours preceding each dose.

Patient Education:

If magnesium is given for the treatment of preterm labor, inform the woman that the efficacy and safety of such use have not been established and that use beyond 5 to 7 days may cause fetal abnormalities. ■ Promptly report symptoms of magnesium toxicity (e.g., difficulty breathing, flushing, sweating, weakness).

Maternal/Child:

Continuous administration beyond 5 to 7 days to pregnant women can lead to hypocalcemia and bone abnormalities in the developing fetus; see Precautions. Use during pregnancy only if clearly needed. ■ Administration of magnesium is not approved for treatment for preterm labor. Safety and efficacy have not been established. Administration of magnesium outside its approved indication in pregnant women should be by trained obstetric personnel in a hospital setting with appropriate obstetric care facilities. ■ A continuous infusion given to control convulsions in toxemic mothers before delivery (especially in the 24 hours preceding) may cause signs of magnesium toxicity in the newborn (e.g., neuromuscular or respiratory depression). ■ Use caution during breast-feeding. ■ Safety for use in pediatric patients not established. Safety and effectiveness has been established for the prevention of eclampsia in adolescents with pre-eclampsia and the treatment of seizures and prevention of recurrent seizures in adolescents with eclampsia.

Elderly:

See Dose Adjustments.

DRUG/LAB INTERACTIONS

Additive CNS depressant effects when used concomitantly with **barbiturates, hypnotics, narcotics, or systemic anesthetics.** See Dose Adjustments and Monitor. ■ Potentiation and prolongation of neuromuscular blockade is possible when used with **neuromuscular blocking agents** (e.g., vecuronium, succinylcholine). Monitor patient closely. Dose adjustment of the neuromuscular blocking agent and reversal agent may be necessary. ■ An exaggerated hypotensive response is possible with concomitant use of magnesium and **dihydropyridine calcium channel blockers** (e.g., amlodipine, nicardipine, nifedipine); monitor vital signs frequently. ■ If **calcium** is used to treat magnesium toxicity, use in digitalized patients may cause serious changes in cardiac conduction, resulting in heart block. Use with extreme caution. ■ **Drugs that may induce magnesium loss** (e.g., alcohol, aminoglycosides, amphotericin B, cisplatin, cyclosporine, digitalis, diuretics) may reduce magnesium concentrations, affecting efficacy; monitor magnesium concentrations closely and adjust dose as needed. ■ Avoid use with **unapproved tocolytics** (e.g., beta-adrenergic agents such as terbutaline or calcium channel blockers such as nifedipine); serious adverse events, including pulmonary edema and hypotension, have occurred.

SIDE EFFECTS

Usually the result of magnesium intoxication. Cardiac and CNS depression proceeding to respiratory paralysis, circulatory collapse, depressed or absent knee jerk reflex, flaccid paralysis, flushing, hypocalcemia with signs of tetany, hypotension, hypothermia, and sweating are most common. Other reported side effects include bradycardia, decreased respiratory rate, hypermagnesemia, lethargy, myasthenic crisis, pulmonary edema, sedation, somnolence, and visual disturbances.

ANTIDOTE

Discontinue the drug and notify the physician of the occurrence of any side effect. An intravenous calcium salt (10 to 20 mL of a 5% solution [diluted if desirable with NS]) may be used to counteract the effects of hypermagnesemia. Physostigmine 0.5 to 1 mg SC may be helpful. Treat hypotension with dopamine. Employ artificial ventilation as necessary and resuscitate as necessary. Hemodialysis is effective in overdose. **Hypermagnesemia in the newborn** may require resuscitation, endotracheal intubation, assisted ventilation, and IV calcium.

MANNITOL

(**MAN**-nih-tol)
Osmitrol
Diuretic (osmotic)
pH 4.5 to 7

USUAL DOSE

Pretreatment:

See Monitor.

Mannitol:

Total dose, concentration, and rate of administration should be based on age, weight, and the nature and severity of the condition being treated, including fluid requirements, electrolyte balance, serum osmolality, urine output, and concomitant therapy.

Reduction of intracranial pressure:

One manufacturer recommends 0.25 Gm/kg as an IV infusion over 30 minutes. May be repeated every 6 to 8 hours. Another manufacturer recommends 0.25 to 2 Gm/kg as a 15% to 25% solution administered as an IV infusion over 30 to 60 minutes.

Reduction of intraocular pressure:

One manufacturer recommends a single dose of 1.5 to 2 Gm/kg of body weight as a 15% or 20% solution administered as an IV infusion over at least 30 minutes. Another manufacturer recommends 0.25 to 2 Gm/kg as a 15% to 25% solution administered as an IV infusion over 30 to 60 minutes. When used preoperatively, administer 60 to 90 minutes before surgery to achieve maximal reduction of intraocular pressure before the operation.

Measurement of glomerular filtration rate (GFR):

Dilute 100 mL of a 20% solution (20 Gm) with 180 mL of NS or 200 mL of a 10% solution (20 Gm) with 80 mL of NS. Infuse the 280 mL of diluted solution at a rate of 20 mL /min. See manufacturer’s prescribing information for diagnostic procedure/monitoring.

PEDIATRIC DOSE

See Maternal/Child.

Cerebral or ocular edema:

1 to 2 Gm/kg of body weight or 30 to 60 Gm/M^2 of body surface as an IV infusion over 30 to 60 minutes.

DOSE ADJUSTMENTS

Reduce dose in small or debilitated patients. One manufacturer states that a dose of 500 mg/kg may be sufficient. ■ Dose selection in the elderly should be cautious (usually starting at the low end of the dosing range), reflecting the greater frequency of decreased organ function and of concomitant disease or drug therapy.

DILUTION

Available in concentrations of 5%, 10%, 15%, 20%, or 25%. May be in flexible IV bags or in flip-top vials. No further dilution is necessary; however, if there are any crystals present in the solution, they must be completely dissolved before administration. One manufacturer recommends: To dissolve crystals in the flexible container, warm the unit to 70° C (158° F) with agitation. Heat solution using a dry-heat cabinet with overwrap intact. Use of a water bath is not recommended. To dissolve the crystals in the flip-top vial, warm the bottle in hot water at 80° C (176° F). Shake vigorously periodically. 25% mannitol injection may be autoclaved at 121° C (250° F) for 20 minutes at 15 psi. Consult prescribing information; process may differ with specific brands. Let cool to at least body temperature before administration.

Glomerular filtration rate:

See Usual Dose.

Filters:

Use an in-line filter for 15%, 20%, and 25% solutions.

Storage:

One manufacturer recommends storing at CRT. Protect from freezing. Do not remove container from overwrap until intended for use. Consult prescribing information; may be brand specific. Discard unused portions.

COMPATIBILITY

Admixing with other medications is not recommended. Do not administer simultaneously with blood products through the same administration set because of the possibility of pseudoagglutination or hemolysis. Concomitant administration of electrolyte-free mannitol solutions with whole blood may cause pseudoagglutination. If blood must be given simultaneously, at least 20 mEq of NaCl should be added to each liter of mannitol solution; consult pharmacist. Do not use PVC infusion bags with 25% mannitol; may form a precipitate.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Variable based on indication and patient condition; see Usual Dose.

ACTIONS

A sugar alcohol effective as an osmotic diuretic. Mannitol hinders the tubular reabsorption of water and enhances excretion of sodium and chloride by elevating the osmolarity of the glomerular filtrate. The increase in extracellular osmolarity induces the movement of intracellular water into the extracellular and vascular spaces. This action is responsible for the ability of mannitol to decrease intracranial pressure and edema and to reduce elevated intraocular pressure. Mannitol is confined to the extracellular space, is only slightly metabolized, and is rapidly excreted by the kidney. It is not reabsorbed or secreted by the tubules of the kidneys. It is excreted almost completely in the urine along with water, sodium, and chloride. Onset of diuresis is 1 to 3 hours. Reduction in intracranial pressure occurs within 15 to 30 minutes. Duration of effect is 1.5 to 6 hours. Half-life is 0.5 to 2.5 hours.

INDICATIONS AND USES

Reduction of intracranial pressure (associated with cerebral edema and/or brain mass) and treatment of cerebral edema. ■ Reduction of elevated intraocular pressure. ■ As a diagnostic for measurement of glomerular filtration rate.

CONTRAINDICATIONS

Anuria, hypersensitivity to mannitol, intracranial bleeding except during craniotomy, pre-existing severe pulmonary vascular congestion or pulmonary edema, severe dehydration (hypovolemia).

PRECAUTIONS

For IV use only, preferably into a large central vein. ■ Serious hypersensitivity reactions, including anaphylaxis, hypotension, and dyspnea resulting in cardiac arrest and death, have been reported. ■ Renal complications, including irreversible renal failure and osmotic nephrosis, have been reported. Although osmotic nephrosis is in principle reversible, it may potentially proceed to chronic or even end-stage renal failure. Patients with pre-existing renal disease, patients with conditions that put them at risk for renal failure, or patients receiving potentially nephrotoxic drugs or other diuretics may be at increased risk for renal failure. ■ Patients with oliguric acute kidney injury who subsequently develop anuria while receiving mannitol are at risk of congestive heart failure, pulmonary edema, hypertensive crisis, coma, and death. ■ CNS toxicity manifested by symptoms such as coma, confusion, and lethargy has been reported. In the presence of impaired renal function, CNS toxicity may result from high serum mannitol concentrations, serum hyperosmolarity resulting in intracellular dehydration within CNS, hyponatremia, or other electrolyte or acid/base disturbances. Deaths have occurred. ■ At high concentrations, mannitol may cross the blood-brain barrier and interfere with the ability of the brain to maintain the pH of the cerebrospinal fluid, especially in the presence of acidosis. In patients with pre-existing compromise of the blood-brain barrier, the risk of increasing cerebral edema (general and focal) associated with repeated or continued use of mannitol must be weighed against expected benefits. ■ A rebound increase of intracranial pressure may occur several hours after a mannitol infusion. Patients with a compromised blood-brain barrier are at increased risk. ■ Depending on dose and duration, mannitol administration may cause hypervolemia, leading to or exacerbating existing congestive heart failure. Accumulation of mannitol due to insufficient renal excretion increases the risk of hypervolemia. Mannitol-induced osmotic diuresis may cause or worsen dehydration/hypovolemia and hemoconcentration. Administration may also cause hyperosmolarity. ■ Depending on dose and duration, mannitol administration may cause electrolyte and acid/base imbalances, which may be fatal. Imbalances may include hypernatremia, dehydration, and hemoconcentration; hyponatremia, which can lead to headache, nausea, seizures, lethargy, coma, cerebral edema, and death (acute symptomatic hyponatremic encephalopathy is a medical emergency); hypokalemia or hyperkalemia, which may result in cardiac adverse reactions, especially in patients receiving drugs that are sensitive to such imbalances; other electrolyte disturbances; and metabolic acidosis/alkalosis. ■ Infusion of mannitol through a peripheral vein at a concentration of 10% or greater may result in peripheral venous irritation, including phlebitis. ■ Use with caution in neurosurgical patients. May increase cerebral blood flow and increase risk of postoperative bleeding. ■ Increased cerebral blood flow may worsen intracranial hypertension in pediatric patients who develop a generalized cerebral hyperemia during the first 24 to 48 hours after injury. ■ See Drug/Lab Interactions.

Monitor:

Evaluate renal, cardiac, and pulmonary status and correct fluid and electrolyte imbalances before administration. ■ During and after infusion for reduction of intracranial pressure, monitor clinical condition; fluid and electrolytes (sodium, potassium, calcium, phosphorus); serum osmolarity; the osmol gap; renal (SCr, urine output); cardiac and pulmonary function; and intracranial pressure. Discontinue if renal, cardiac, or pulmonary status worsen or if CNS toxicity develops. ■ Monitor for S/S of a hypersensitivity reaction. ■ Observe infusion site to prevent infiltration.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., dyspnea, itching, rash). ■ Report any adverse reaction, such as change in mental status, decreasing urine output, difficulty breathing, edema, or new or worsening heart failure. ■ Report pain at injection site.

Maternal/Child:

Safety for use in pregnancy, labor, or delivery not established. Mannitol crosses the placenta and may cause fluid shifts that could potentially result in adverse effects in the fetus. Benefits must outweigh risks. ■ Use caution in breast-feeding. ■ Mannitol is approved for use in pediatric patients for the reduction of intracranial and intraocular pressure. Studies have not identified the optimal dose in this patient population. The safety profile for use in pediatric patients is similar to that seen with adults. ■ Pediatric patients under 2 years of age, particularly preterm and term neonates, may be at higher risk for fluid and electrolyte abnormalities after mannitol administration because of decreased glomerular filtration rate and limited ability to concentrate urine. ■ See Precautions.

Elderly:

Response similar to that seen in younger patients. Lower-end initial doses may be appropriate; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May increase **lithium** excretion, thereby decreasing its effectiveness. May also increase risk of lithium toxicity in patients who develop mannitol-induced hypovolemia or renal impairment. Consider holding lithium during treatment with mannitol. If concomitant administration of lithium and mannitol is required, monitor lithium levels carefully. ■ Mannitol-induced electrolyte imbalances (e.g., hyperkalemia, hypokalemia) may result in cardiac adverse reactions in patients receiving drugs that are sensitive to such imbalances (e.g., **digoxin, drugs that prolong the QT interval, neuromuscular blocking agents**). ■ Use with **potentially nephrotoxic drugs** (e.g., aminoglycosides) or other **diuretics** may increase the risk of renal toxicity. Avoid concomitant use, if possible. ■ Concomitant administration of **systemic neurotoxic drugs** (e.g., aminoglycosides) may potentiate neurotoxicity. Avoid concomitant use, if possible. ■ High concentrations of mannitol can cause false low results for inorganic phosphorus blood concentrations with certain assays. ■ Mannitol may produce a false-positive result in tests for blood ethylene glycol concentrations.

SIDE EFFECTS

The most common adverse reactions are CNS toxicity, hypersensitivity reactions, hypokalemia, hyperkalemia, hyponatremia, hypernatremia, hypovolemia, hypervolemia, infusion site reactions, and renal failure; see Precautions. Other reactions may include acidosis, backache, blurred vision, chest pain, chills, convulsions, decreased chloride levels, dehydration, diuresis, dizziness, dryness of mouth, edema, fever, fulminating congestive heart failure, headache, hyperosmolality, hypertension, hypotension, nausea, polyuria then oliguria, pulmonary edema, rhinitis, tachycardia, thirst, thrombophlebitis, and urinary retention.

ANTIDOTE

If minor side effects persist, notify the physician. Discontinue at the first sign of a hypersensitivity reaction and initiate therapeutic measures as clinically indicated. Discontinue for worsening renal function, CNS toxicity, or for fluid, electrolyte, or acid/base abnormalities and notify the physician. Treatment will be supportive to correct fluid and electrolyte imbalances. Hemodialysis may be used to clear mannitol and reduce serum osmolality.

MECHLORETHAMINE HYDROCHLORIDE BBW

(meh-klor-**ETH**-ah-meen hy-droh-**KLOR**-eyed)
HN_2, Mustargen, Nitrogen Mustard
Antineoplastic (alkylating agent/nitrogen mustard)
pH 3 to 5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

0.4 mg/kg of body weight as a single dose is preferred, or may be divided into 2 to 4 equal doses and given daily for 2 to 4 days. Allow about 3 to 6 weeks between courses of therapy. Confirm bone marrow recovery. Results with subsequent courses are rarely as satisfactory as the initial course (MOPP regimen).

Hodgkin disease:

6 mg/M^2 on Days 1 and 8 of a monthly treatment cycle.

DOSE ADJUSTMENTS

Dose based on ideal dry body weight in the presence of ascites or edema. ■ Lower-end doses may be indicated in the elderly. Consider impaired organ function and concomitant disease or other drug therapy. ■ Used with other chemotherapeutic agents to produce tumor remission. ■ See Drug/Lab Interactions.

DILUTION

Specific techniques required; see Precautions. Highly toxic. Both powder and solution must be handled with care. Mix solution immediately before use. Very unstable. Dilute each 10-mg vial with 10 mL of SW or NS. Do not remove needle and syringe. Hold securely and shake vial to dissolve completely. Contains 1 mg/mL. Withdraw desired dose. Do not use if solution is discolored or if droplets of water remain isolated in the vial. May be given by IV injection, but administration through a Y-tube or three-way stopcock of a free-flowing infusion is preferred. Neutralize unused portion with equal volumes of 5% sodium thiosulfate and 5% sodium bicarbonate solution and let stand 45 minutes, then discard appropriately.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Protect from light and humidity. Solutions of mechlorethamine decompose rapidly; prepare immediately before administration.

COMPATIBILITY

Rapidly decomposes in IV solutions; addition not recommended.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Total daily dose equally distributed over 3 to 5 minutes.

ACTIONS

An alkylating agent, cell cycle phase–nonspecific, with antitumor activity. It has a selective cytotoxic effect on rapidly growing cells. Palliative, not curative, in its effects; regression in the size of malignant tumor may occur; pain and fever subside; appetite, strength, and a sense of well-being are increased. Rapidly metabolized. Excreted in changed form in the urine.

INDICATIONS AND USES

Used intravenously for the palliative treatment of Hodgkin disease (Stages III and IV), lymphosarcoma, chronic myelocytic or chronic lymphocytic leukemia, polycythemia vera, mycosis fungoides, and bronchogenic carcinoma. ■ Used intrapleurally, intraperitoneally, or intrapericardially for the palliative treatment of metastatic carcinoma resulting in effusion.

CONTRAINDICATIONS

Not recommended in patients with infectious disease, previous anaphylactic reactions, or in terminal stages of malignancy.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Administered by or under direction of the physician specialist. ■ Highly toxic; a probable carcinogen, mutagen, and teratogen. Avoid exposure during pregnancy. Both powder and solution must be handled and administered with care. Inhalation of dust or vapors and contact with skin or mucous membranes, especially those of the eyes, must be avoided at any stage of mixing, administration, or destruction. For accidental contact, copious irrigation with water for at least 15 minutes is indicated. Follow with rinse of 2% sodium thiosulfate and seek medical attention. If accidental eye exposure occurs, irrigate for 15 minutes with water, NS, or a balanced salt ophthalmic irrigating solution and seek ophthalmologic consultation. Contaminated clothing should be removed and destroyed. ■ Use precaution with radiation therapy, other chemotherapy, severe leukopenia, thrombocytopenia, anemia, and bone marrow infiltrated with malignant cells. ■ If acute or chronic suppurative inflammation is present, do not use nitrogen mustard. May cause rapid development of amyloidosis.

Monitor:

Extremely narrow margin of safety; dose must be individualized. ■ Obtain baseline and monitor CBC and differential frequently, including platelets and renal and hepatic function. ■ Monitor uric acid levels before and during treatment; allopurinol may prevent formation of uric acid crystals. ■ Extravasation into surrounding tissue can cause sloughing and possible necrosis; see Antidote. ■ Often given in the late evening with antiemetics and sedatives to promote patient comfort. ■ Maintain adequate hydration. ■ Observe closely for all signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/ mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Report IV site burning or stinging promptly. ■ Effective birth control recommended. ■ See Appendix D.

Maternal/Child:

Category D: avoid pregnancy. May produce teratogenic effects on the fetus. Has mutagenic potential. ■ Discontinue breast-feeding. ■ Limited use in pediatric patients; safety not established.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Alkylating agents interact with **radiation therapy, other antineoplastics, and other bone marrow suppressants** (e.g., doxorubicin [Adriamycin], vincristine) to produce serious reaction. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Alopecia, anaphylaxis, anorexia, bleeding, bone marrow suppression (granulocytopenia, leukopenia, lymphocytopenia, pancytopenia, thrombocytopenia), cerebrovascular accidents, delayed catamenia, depression of formed elements in circulating blood, diarrhea, hemolytic anemia, hyperuricemia, jaundice, nausea, petechiae, sloughing, susceptibility to infection, tinnitus, thrombophlebitis, vertigo, vomiting, weakness, death. Bone marrow suppression may be found up to 50 days or more after starting therapy. Hemorrhagic complications may be due to hyperheparinemia.

ANTIDOTE

For external contact and cleaning purposes, use a 2% sodium thiosulfate solution. ■ To prevent sloughing and necrosis in areas where extravasation has occurred, inject isotonic sodium thiosulfate with a fine hypodermic needle into the indurated area. Apply ice compress for 6 to 12 hours. Elevate extremity. See package insert for instructions on preparation of isotonic thiosulfate. ■ Notify physician of any side effect. Discontinue the drug and use supportive therapy as necessary to sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity.

MELOXICAM INJECTION BBW

(mel-**OKS**-i-kam in-**JEK**-shun)
Anjeso
Analgesic
NSAID

USUAL DOSE

Pretreatment:

See Monitor and Maternal/Child. To reduce the risk of renal toxicity, patients must be well hydrated before administration.

Use the lowest effective dose for the shortest duration consistent with individual patient treatment goals.

Meloxicam:

Recommended dose is 30 mg once daily as an IV bolus injection over 15 seconds. Meaningful pain relief may not occur for 2 to 3 hours after meloxicam injection. A non-NSAID analgesic with a rapid onset of effect may be needed; see Monitor.

DOSE ADJUSTMENTS

No specific dose adjustments recommended. ■ Has not been studied in patients with hepatic impairment or in patients with moderate or severe renal impairment. ■ Consider dose reduction in patients who are known or suspected to be poor CYP2C9 metabolizers based on genotype or previous history/experience with other CYP2C9 substrates (e.g., warfarin or phenytoin). May have abnormally high concentrations due to reduced metabolic clearance.

DILUTION

Available as an opaque, pale yellow, aqueous dispersion for IV use supplied as a 1-mL fill (30 mg/mL) in a clear, 2-mL, single-dose vial.

Filters:

Specific information not available.

Storage:

Store at CRT. Protect from light. ***Do not freeze.***

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV bolus over 15 seconds.

ACTIONS

A nonsteroidal anti-inflammatory drug (NSAID) that has anti-inflammatory, analgesic, and antipyretic activity. Mechanism of action is not completely understood but may involve inhibition of the cyclooxygenase (COX-1 and COX-2) pathways. Meloxicam is a potent inhibitor of prostaglandin synthesis. Prostaglandins sensitize afferent nerves and potentiate the action of bradykinin in inducing pain in animal models. Prostaglandins are mediators of inflammation. Because meloxicam is an inhibitor of prostaglandin synthesis, its mode of action may result from a decrease of prostaglandins in peripheral tissues. More than 99% bound to serum proteins, primarily albumin. Metabolized extensively in the liver, primarily by CYP2C9. Mean elimination half-life is approximately 24 hours. Excreted as metabolites in urine and feces.

INDICATIONS AND USES

An NSAID indicated in adults for the management of moderate to severe pain alone or in combination with other non-NSAID analgesics.

Limitation of Use:

Because of delayed onset of analgesia, meloxicam is not recommended for use when rapid onset of analgesia is required.

CONTRAINDICATIONS

Known hypersensitivity to meloxicam or any components of the drug product. ■

History of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs. ■ Contraindicated in the setting of coronary artery bypass graft (CABG) surgery. ■ Moderate to severe renal insufficiency patients who are at risk for renal failure due to volume depletion.

PRECAUTIONS

For IV administration only. ■ Nonsteroidal anti-inflammatory drugs (NSAIDs) cause an increased risk of serious cardiovascular (CV) thrombotic events, including myocardial infarction and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. Patients with cardiovascular disease or risk factors for cardiovascular disease may be at greater risk. Some observational studies found that this increased risk of serious CV thrombotic events began as early as the first weeks of treatment. The increase in CV thrombotic risk has been observed most consistently at higher doses. To minimize the potential risk, use the lowest effective dose for the shortest duration possible. ■ In observational studies, patients treated with NSAIDs in the post-MI period were at increased risk for re-infarction, CV-related death, and all-cause mortality beginning in the first week of treatment. Avoid use in patients with recent MI unless benefits are expected to outweigh the risk of recurrent CV thrombotic events. ■ There is no consistent evidence that concurrent use of aspirin mitigates the increased risk of serious CV thrombotic events associated with NSAID use. Concurrent use of aspirin and an NSAID does increase the risk of serious GI events. ■ NSAIDs increase the risk of serious gastrointestinal (GI) adverse events, including inflammation, bleeding, ulceration, and perforation of the esophagus, stomach, or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients and patients with a prior history of peptic ulcer disease and/or GI bleeding are at greater risk for serious gastrointestinal events. ■ Risk of GI events increases with longer duration of use; however, even short-term use is not without risk. Use with extreme caution in patients with a history of ulcer disease or GI bleeding. ■ Other factors that increase the risk for GI bleeding include concomitant use of oral corticosteroids, aspirin, anticoagulants, or selective serotonin reuptake inhibitors (SSRIs [e.g., fluoxetine]); smoking; use of alcohol; older age; and poor general health. ■ In addition, patients with advanced liver disease and/or coagulopathy are at increased risk for GI bleeding. Most reports of spontaneous fatal GI events are in patients who are elderly or debilitated. Avoid use in patients at higher risk unless benefits are expected to outweigh the increased risk of bleeding. Alternate therapies should be considered. ■ Elevations of ALT or AST 3 or more times the ULN have been reported. In addition, rare, sometimes fatal, cases of severe hepatic injury, including fulminant hepatitis, liver necrosis, and hepatic failure, have been reported. ■ NSAIDs, including meloxicam, can lead to new onset of hypertension or worsening of pre-existing hypertension, either of which may contribute to the increased incidence of cardiovascular events. ■ In patients with heart failure, NSAID use increased the risk of MI, hospitalization for heart failure, and death. Avoid use in patients with severe heart failure unless benefits outweigh the risk of worsening heart failure. ■ Fluid retention and edema have been observed. ■ Long-term administration of NSAIDs has resulted in renal papillary necrosis, renal insufficiency, acute renal failure, and other renal injury. Renal toxicity has also been seen in patients in whom renal prostaglandins have a compensatory role in the maintenance of renal perfusion. NSAIDs may cause a dose-dependent reduction in prostaglandin formation and, secondarily, in renal blood flow, which may precipitate overt renal decompensation. Patients at greatest risk are those with impaired renal function, dehydration, hypovolemia, heart failure, or liver dysfunction; those taking diuretics and ACE (angiotensin-converting enzyme) inhibitors or ARBs (angiotensin receptor blockers); and elderly patients. ■ Increases in serum potassium concentration, including hyperkalemia, have been reported. ■ Meloxicam has been associated with hypersensitivity reactions (including anaphylactic reactions) with and without known hypersensitivity to meloxicam and in patients with aspirin-sensitive asthma. ■ Use with caution in patients with asthma. Use is contraindicated in patients with aspirin-sensitive asthma (a subpopulation of patients with asthma that may include chronic rhinosinusitis complicated by nasal polyps; severe, potentially fatal bronchospasm; and/or intolerance to aspirin and other NSAIDs). Cross-reactivity between aspirin and other NSAIDs has been reported in such aspirin-sensitive patients. ■ NSAIDs can cause serious skin adverse events such as exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN), which may occur without warning and can be fatal. ■ Anemia has occurred in NSAID-treated patients. May be due to occult or gross blood loss, fluid retention, or an incompletely described effect on erythropoiesis. ■ By reducing inflammation, and possibly fever, meloxicam may diminish the S/S of infection.

Monitor:

Correct hypovolemia before administration and maintain adequate hydration. ■ Obtain baseline blood pressure and monitor frequently during therapy. ■ Baseline CBC, chemistry profile, liver function tests, and SCr may be useful. Repeat as indicated in patients at risk for toxicity or if symptoms of toxicity develop. ■ When initiating meloxicam, monitor patient analgesic response. Because the median time to meaningful pain relief was 2 and 3 hours after meloxicam administration in two clinical studies, a non-NSAID analgesic with a rapid onset of effect may be needed, for example, upon anesthetic emergence or resolution of local or regional anesthetic blocks. ■ Some patients may not experience adequate analgesia for the entire 24-hour dosing interval and may require administration of a short-acting, non-NSAID, immediate-release analgesic. ■ Monitor renal function in patients with renal or hepatic impairment, heart failure, dehydration, or hypovolemia. ■ CV events (e.g., MI, stroke, other thrombotic events) may occur even in the absence of previous CV symptoms. Monitor patients with or without a previous history of CV disease for S/S of thromboembolic complications (e.g., altered consciousness, vision, or speech; chest pain; limb or abdominal swelling and/or pain; loss of sensation or motor power; shortness of breath). If used in patients with a recent MI, monitor for signs of cardiac ischemia. ■ Monitor for edema, weight gain, or signs of worsening heart failure. ■ To minimize the GI risks in NSAID-treated patients: (1) use the lowest effective dosage for the shortest possible duration; (2) avoid administration of more than one NSAID at a time; (3) avoid use in patients at higher risk unless benefits are expected to outweigh increased risk of bleeding (for such patients, as well as those with active GI bleeding, consider alternate therapies); (4) observe for S/S of GI ulceration or bleeding; (5) promptly initiate evaluation and treatment if a serious GI adverse event is suspected, and discontinue meloxicam until a serious GI event is ruled out; (6) during concomitant use of low-dose aspirin for cardiac prophylaxis, monitor patients more closely for evidence of GI bleeding. ■ Observe for S/S of liver dysfunction (e.g., abdominal pain, dark urine, diarrhea, elevated LFTs, eosinophilia, fatigue, jaundice, pruritus, rash). ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, pruritus, rash, urticaria, or wheezing). If used in patients with pre-existing asthma (without known aspirin sensitivity), monitor patients for changes in the S/S of asthma. ■ Monitor for S/S of serious skin reactions (e.g., rash). ■ Monitor patients who may be at increased risk for bleeding; see Precautions.

Patient Education:

Side effects have resulted in extended hospitalization and could be fatal. ■ Promptly report any unusual S/S suggestive of thromboembolic events, GI toxicity, hepatotoxicity, hypersensitivity reactions, or fluid and electrolyte imbalance (e.g., abdominal pain, bloody emesis, changes in vision, chest pain, dark stools, diarrhea, dizziness, fatigue, flu-like symptoms, jaundice, lethargy, nausea, numbness of face or limbs, pruritus, rash, shortness of breath, unexplained weight gain or edema). ■ Review medication profile with physician or pharmacist. ■ May delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women. ■ May compromise fertility in males of reproductive potential.

Maternal/Child:

May cause premature closure of the fetal ductus arteriosus. Avoid use in pregnant women starting at 30 weeks' gestation (third trimester). There are no adequate and well-controlled studies of meloxicam in pregnant women. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ There are no studies on the use of meloxicam during labor or delivery. Inhibition of prostaglandin synthesis, delayed parturition, and increased incidence of stillbirth were seen in animal studies. ■ Use caution during breast-feeding; data unavailable. ■ Safety and efficacy have not been established for use in pediatric patients.

Elderly:

Safety and effectiveness similar to younger patients. However, elderly patients are at greater risk for serious, NSAID-associated cardiovascular, gastrointestinal, and/or renal adverse reactions. If used, monitor closely.

DRUG/LAB INTERACTIONS

Concurrent use with **drugs that interfere with hemostasis** (e.g., aspirin, SSRIs, SNRIs, warfarin, and other NSAIDs) is not recommended; may increase the risk of serious GI events. ■ Concomitant use with analgesic doses of **aspirin** is not generally recommended. In the setting of concomitant use of **low-dose aspirin** for cardiac prophylaxis, monitor patients more closely for evidence of GI bleeding. Meloxicam is not a substitute for low-dose aspirin for cardiovascular protection. ■ The effects of **anticoagulants** (e.g., heparin, warfarin) and NSAIDs on bleeding are synergistic; risk of bleeding increases with concomitant use. ■ NSAIDs may decrease the antihypertensive effect of **ACE inhibitors, angiotensin receptor blockers** (ARBs), and **beta-blockers**. Monitor blood pressure to ensure desired BP is maintained.

Monitor renal function to identify possible renal deterioration in elderly patients, volume-depleted patients (including those on diuretic therapy), and/or patients with renal impairment. ■ Use caution if administered concomitantly with **cyclosporine**; cyclosporine nephrotoxicity may be increased. ■ Meloxicam can reduce the natriuretic effects of **loop diuretics** and **thiazide diuretics**. This response is thought to be due to inhibition of renal prostaglandin synthesis; observe for signs of worsening renal function and ensure diuretic effectiveness. ■ Concurrent use of **lithium** with NSAIDs may decrease lithium clearance, increasing plasma levels of lithium; observe for signs of lithium toxicity. ■ Concurrent use of NSAIDs with **methotrexate** may enhance methotrexate toxicity. Observe for signs of methotrexate toxicity (neutropenia, thrombocytopenia, renal dysfunction). ■ Concomitant use of meloxicam and **pemetrexed** may increase the risk of pemetrexed-associated myelosuppression and renal and GI toxicity. ■ Concomitant use with other **NSAIDs or salicylates** (e.g., diflunisal, salsalate) increases the risk of GI toxicity with little or no increase in efficacy. ■ Metabolized by cytochrome P450 enzymes, predominantly by CYP2C9. Coadministration with **CYP2C9 inhibitors** (e.g., amiodarone, fluconazole, voriconazole) may increase the toxicity of meloxicam. Consider dose reduction in patients undergoing treatment with CYP2C9 inhibitors, and monitor for adverse effects.

SIDE EFFECTS

Most common side effects include anemia, constipation, and increased gamma-glutamyl transferase (GGT). Serious side effects include cardiovascular thrombotic events; GI bleeding, ulceration, and perforation; hepatotoxicity; hypertension; heart failure and edema; renal toxicity and hyperkalemia; anaphylactic reactions; serious skin reactions; and hematologic toxicity. Many other side effects have been reported in fewer than 2% of patients during clinical trials.

Overdose:

Drowsiness, epigastric pain, lethargy, nausea, and vomiting are common and have been generally reversible with supportive care. Acute renal failure, coma, GI bleeding, hypertension, and respiratory depression have occurred but were rare.

Post-Marketing:

Acute urinary retention, agranulocytosis, alterations in mood (such as mood elevation), anaphylactoid reactions (including shock), erythema multiforme, exfoliative dermatitis, interstitial nephritis, jaundice, liver failure, Stevens-Johnson syndrome, toxic epidermal necrolysis, and female infertility.

ANTIDOTE

Keep the physician informed of side effects. With increasing severity or onset of symptoms of any major side effect (e.g., cardiovascular thrombotic events; CHF; edema; GI bleeding, ulceration, or perforation; hepatic or renal toxicity; hypersensitivity reactions; hypertension; skin reactions), discontinue the drug and notify the physician. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly if indicated. Treat anaphylaxis with epinephrine, diphenhydramine, and corticosteroids as indicated. Manage overdose with symptomatic and supportive care. No specific antidote. Forced diuresis, alkalinization of urine, hemodialysis, or hemoperfusion may be used in an overdose situation but are unlikely to be useful due to high protein binding. Accelerated removal of meloxicam with cholestyramine 4 Gm three times daily was demonstrated in a clinical trial and may be useful in overdose.

MEPERIDINE HYDROCHLORIDE BBW

(meh-**PER**-ih-deen hy-droh-**KLOR**-eyed)
Demerol, Demerol HCl, Meperidine HCl PF
Opioid analgesic
(agonist)
Anesthesia adjunct
pH 3.5 to 6

USUAL DOSE

Individualize dose, taking into account the patient's severity of pain, patient response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient's treatment goals.

Management of pain:

50 to 150 mg IM or SC every 3 to 4 hours as needed for pain. If IV administration is required, dosage should be decreased and the injection made very slowly, preferably using a diluted solution.

Infusion (unlabeled):

15 to 35 mg/hr; see Precautions.

Supplement anesthesia:

1 to 10 mg/mL dilution is usually used. Titrate under the direct observation and control of the anesthesiologist. Dose dependent on premedication, type of anesthesia, type and duration of procedure, and patient's condition.

Treatment or prevention of shaking chills (unlabeled):

12.5 to 50 mg.

PEDIATRIC DOSE

1.1 to 1.8 mg/kg/dose IM or SC; see comments under Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Reduced dose may be required in the elderly or debilitated, in hepatic or renal disease, or in numerous other disease states; see Precautions. ■ Doses appropriate for the general population may cause serious respiratory depression in vulnerable patients. ■

Increase doses as required if analgesia is inadequate, tolerance develops, or pain severity increases. The first sign of tolerance is usually a reduced duration of effect. ■ Decrease dose by 25% to 50% when administered concomitantly with phenothiazines and other centrally acting medications (e.g., sedatives). ■ See Drug/Lab Interactions.

DILUTION

IV injection:

May be given undiluted; however, further dilution with 5 mL of SWFI, NS, or other IV solutions to facilitate titration is appropriate; see chart on inside back cover.

Filters:

No data available from manufacturer.

Storage:

Before use, store at CRT protected from light. Do not freeze.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 4 to 5 minutes. Frequently titrated according to symptom relief and respiratory rate. Rapid IV administration increases the possibility of hypotension and respiratory depression.

ACTIONS

A synthetic opioid agonist similar to morphine. Has multiple actions; the most prominent involve the CNS and organs composed of smooth muscle. Principal actions of therapeutic value are analgesia and sedation. A parenteral dose of meperidine 60 to 80 mg is approximately equivalent in analgesic effect to 10 mg of morphine. Onset of action occurs in about 5 minutes and lasts for about 2 to 3 hours. Metabolized to an active, toxic metabolite (normeperidine) in the liver. The half-life of meperidine is 2 to 5 hours. The half-life of normeperidine is 15 to 30 hours. This extended half-life may lead to cumulative effects. Excreted in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of pain severe enough to require an opioid analgesic and for which alternative treatments are inadequate. ■ Preoperative medication. ■ Support of anesthesia. ■ Obstetric analgesia.

Unlabeled uses:

Treatment or prevention of shaking chills (rigors) caused by some medications (e.g., amphotericin B [all formulations], aldesleukin [Proleukin]). ■ Treatment of postoperative shivering.

Limitations of use:

Because of the risk of addiction, abuse, and misuse, even at recommended doses, reserve meperidine for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated
- Have not provided adequate analgesia or are not expected to provide adequate analgesia

Meperidine should not be used for treatment of chronic pain. Prolonged use may increase the risk of toxicity (e.g., seizures) from accumulation of the meperidine metabolite normeperidine.

CONTRAINDICATIONS

Significant respiratory depression. ■ Acute or severe bronchial asthma in the absence of resuscitation equipment or in unmonitored settings. ■ Known or suspected GI obstruction, including paralytic ileus. ■ Hypersensitivity to meperidine. ■ Patients who have received MAO inhibitors (e.g., selegiline [Eldepryl]) in the previous 14 days.

PRECAUTIONS

Meperidine exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient’s risk before prescribing meperidine, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Serious, life-threatening, or fatal respiratory depression may occur with the use of meperidine. Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), emergency drugs, resuscitative and intubation equipment, and oxygen should be readily available. ■ Use of meperidine as a first-line analgesic for pain is discouraged due to its short duration of action and the risk of accumulation of its toxic metabolite, normeperidine. Accumulation of normeperidine may increase the risk of toxicity (e.g., seizures). If its use in acute pain (in patients without renal or CNS disease) cannot be avoided, the American Pain Society and ISMP recommend limiting treatment to 48 hours or less and not exceeding 600 mg/24 hr. ■ Use with extreme caution in patients with COPD, cor pulmonale, a substantially decreased respiratory reserve, hypercapnia, hypoxia, or pre-existing respiratory depression; these patients are at increased risk for decreased respiratory drive, including apnea, even at recommended doses. Consider using nonopioid analgesics, or administer under careful medical supervision at the lowest effective dose. ■ Use with caution and reduce initial doses in elderly, cachectic, or debilitated patients and in patients with severe impairment of hepatic, pulmonary, or renal function. Consider using nonopioid analgesics. ■ Cases of serotonin syndrome have been reported during concomitant use of meperidine with serotonergic drugs. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. Avoid use in patients with impaired consciousness or coma. ■ Cases of adrenal insufficiency have been reported with opioid use, more often after more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried, because some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ May increase the frequency of seizures in patients with a convulsive disorder and may induce or aggravate seizures in some clinical settings. Prolonged meperidine use may increase the risk of seizures from the accumulation of the meperidine metabolite normeperidine. ■ May cause severe hypotension in postoperative patients or in any patient whose ability to maintain blood pressure has been compromised by depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines). In patients with circulatory shock, meperidine-induced vasodilation may further reduce cardiac output and blood pressure. Use should be avoided. ■ Meperidine may provoke hypertension in patients with pheochromocytoma. ■ Use with caution in patients with atrial flutter and other supraventricular tachycardias; may produce a significant increase in ventricular response rate due to a possible vagolytic action. ■ Do not abruptly discontinue meperidine in a patient who is physically dependent; dose must be tapered gradually. ■ See Drug/Lab Interactions.

Monitor:

Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. Oxygen, naloxone, and equipment to establish and maintain an airway must be available. ■ Assess baseline pain, reassess after administration of meperidine, and adjust dose or interval as required. ■ Monitor vital signs and oxygenation and observe patient frequently. ■ Keep patient supine; orthostatic hypotension and fainting may occur; less likely with continuous low doses, but observe closely during ambulation. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ With use, the active metabolite normeperidine may accumulate to toxic levels; will lower seizure threshold. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovery from sleep deprivation. ■ Laxatives with or without stool softeners may be required to avoid constipation and fecal impaction. Maintain adequate hydration. ■ Monitor patients regularly for the development of opioid addiction, abuse, and misuse.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). Review all medications for interactions. ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ Promptly report unrelieved pain or unacceptable side effects. ■ Promptly report S/S of serotonin syndrome. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended.

Maternal/Child:

Not recommended for use during pregnancy or before labor when other analgesic techniques are more appropriate. ■ Use during delivery may cause depression of respiration and psychophysiologic effects in the newborn. May also prolong labor by reducing the strength, duration, and frequency of contractions (this effect is not consistent). Closely monitor neonates exposed to meperidine during labor and delivery for signs of excessive sedation and respiratory depression. ■ Prolonged use of meperidine during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. Infants born to mothers receiving meperidine during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome, if indicated. See literature for treatment protocols. ■ Use caution with breast-feeding. Monitor infants exposed to meperidine through breast milk for excess sedation and respiratory depression. Withdrawal symptoms can occur in breast-fed infants when maternal administration of an opioid analgesic is stopped or when breast-feeding is stopped. ■ Safety and effectiveness of meperidine in pediatric patients has not been established. Consider risk versus benefit before use in neonates or young infants. Rate of elimination is slower in neonates and young infants compared to older pediatric patients or adults. May be more sensitive to effects (e.g., respiratory depression).

Elderly:

See Dose Adjustments and Precautions. ■ May be more sensitive to effects (e.g., respiratory depression, CNS depression, constipation, urinary retention). Respiratory depression is the chief risk for elderly patients treated with opioids. ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Concomitant use of meperidine with **monoamine oxidase (MAO) inhibitors** (e.g., selegiline [Eldepryl], phenelzine [Nardil], tranylcypromine [Parnate], linezolid [Zyvox]) can result in coma, severe respiratory depression, cyanosis, and hypotension; see Contraindications. Severe and unpredictable potentiation of **MAO inhibitors** has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). ■ Concomitant use of meperidine with **benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]) and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required, and monitor patients carefully for S/S of respiratory depression and sedation. ■ Use caution with concomitant use of meperidine and **CYP3A4 or CYP2B6 inhibitors** (e.g., macrolide antibiotics [e.g., erythromycin (Erythrocin)], azole antifungals [e.g., ketoconazole (Nizoral)], and protease inhibitors [e.g., ritonavir (Norvir)]) or when discontinuing a **CYP3A4 or CYP2B6 inducer** (e.g., rifampin [Rifadin], carbamazepine [Tegretol], phenytoin [Dilantin]) in an meperidine-treated patient. May increase plasma concentration of meperidine, increase or prolong opioid adverse effects, and cause potentially fatal respiratory depression. Dose reduction may be indicated. ■ Alternatively, concomitant use of meperidine with **CYP3A4 or CYP2B6 inducers** or discontinuation of a **CYP3A4 or CYP2B6 inhibitor** could result in lower than expected meperidine plasma concentration and decreased efficacy. An increase in the dose of meperidine may be required. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including meperidine, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ **Mixed agonist/antagonist analgesics and partial agonists** (e.g., buprenorphine [Buprenex], butorphanol [Stadol], nalbuphine, pentazocine [Talwin]) may reduce the analgesic effect of meperidine and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Meperidine may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine [Flexeril], orphenadrine [Norflex]), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ Concomitant use of **acyclovir (Zovirax)** may increase plasma concentrations of meperidine and normeperidine. Monitor for respiratory depression and sedation. ■ Concomitant use of **cimetidine (Tagamet)** may reduce the clearance and volume of distribution of meperidine and the formation of normeperidine. Monitor for respiratory depression and sedation.

SIDE EFFECTS

The most common adverse reactions are dizziness, light-headedness, nausea, sedation, sweating, and vomiting. The most serious side effects reported are respiratory depression and, to a lesser degree, circulatory depression. Respiratory arrest, cardiac arrest, and shock have occurred. Other reported adverse reactions include agitation, anaphylaxis, biliary tract spasm, bradycardia, confusion, constipation, convulsions, delirium, dry mouth, flushing, headache, hypersensitivity reactions, hypotension, involuntary muscle movements, mood changes, palpitations, phlebitis, postural hypotension, pruritus, rash, restlessness, syncope, tachycardia, transient hallucinations and disorientation, tremor, urinary retention, urticaria, visual disturbances, and weakness.

Overdose:

Apnea, atypical snoring, bradycardia, cardiac arrest, circulatory depression or collapse, cold and clammy skin, constricted pupils, hypotension (severe), partial or complete airway obstruction, respiratory depression or arrest, skeletal muscle flaccidity, somnolence progressing to stupor or coma, and death.

ANTIDOTE

With increasing severity of minor side effects or onset of any major side effect, discontinue the drug and notify the physician. A patent airway, artificial respiration, oxygen therapy, and other symptomatic treatment must be instituted promptly. Naloxone hydrochloride will reverse cardiovascular, CNS, and respiratory reactions. In patients who are physically dependent on narcotics, use extreme caution to avoid precipitating an acute withdrawal syndrome. If use of an antagonist is needed in a physically dependent patient, begin administration of the antagonist at a lower than usual dose and titrate with care. In all patients, adjust and titrate the dose of a narcotic antagonist to reverse side effects without reversing pain control. Avoid total reversal of pain control. The duration of action of meperidine may exceed the duration of action of naloxone. Monitor patient carefully. Repeat doses of naloxone may be required. IV hydrocortisone or prednisolone and chlorpromazine have been used to treat severe reactions (e.g., hypertension, hyperpyrexia) in patients who inadvertently receive an MAO inhibitor and meperidine. The usefulness and safety of narcotic antagonists in treatment of these reactions is unknown; see Contraindications and Drug/Lab Interactions. Resuscitate as necessary.

MEROPENEM

(**mer**-oh-**PEN**-em)
Merrem I.V.
Antibacterial (carbapenem)
pH 7.3 to 8.3

USUAL DOSE

Dose ranges from 500 mg to 2 Gm and depends on type and severity of infection.

Complicated skin and skin structure infections in adults and pediatric patients weighing 50 kg or more:

500 mg every 8 hours. Increase to 1 Gm every 8 hours in complicated skin and skin structure infections caused by *Pseudomonas aeruginosa*.

Complicated intra-abdominal infections in adults and pediatric patients weighing 50 kg or more:

1 Gm every 8 hours.

Febrile neutropenia in adults and pediatric patients weighing 50 kg or more (unlabeled):

1 Gm every 8 hours.

Meningitis (unlabeled in adult patients):

2 Gm every 8 hours.

Bloodstream infections (gram-negative bacteremia) (unlabeled):

1 Gm every 8 hours.

Melioidosis *(Burkholderia pseudomallei)* (unlabeled):

1 Gm every 8 hours.

Mild to moderate infection, other severe infections (unlabeled):

500 mg to 1 Gm every 8 hours.

Complicated urinary tract infections (unlabeled):

500 mg to 1 Gm every 8 hours.

PEDIATRIC DOSE

30 to 120 mg/kg/day divided (10 to 40 mg/kg) every 8 hours depending on type and severity of infection. Maximum dose is 6 Gm/day. See Maternal/Child.

Complicated skin and skin structure infections in pediatric patients 3 months of age and older:

10 mg/kg every 8 hours. Maximum single dose every 8 hours is 500 mg. Increase dose to 20 mg/kg every 8 hours in complicated skin and skin structure infections caused by *P. aeruginosa*. Maximum single dose every 8 hours is 1 Gm.

Complicated intra-abdominal infections in pediatric patients 3 months of age and older:

20 mg/kg every 8 hours. Maximum single dose every 8 hours is 1 Gm.

Complicated intra-abdominal infections in pediatric patients under 3 months of age:

Dose is based on gestational age (GA) and postnatal age (PNA).

Infants under 32 weeks GA and PNA under 2 weeks:

20 mg/kg every 12 hours.

Infants under 32 weeks GA and PNA 2 weeks and older:

20 mg/kg every 8 hours.

Infants 32 weeks and older GA and PNA under 2 weeks:

20 mg/kg every 8 hours.

Infants 32 weeks and older GA and PNA 2 weeks and older:

30 mg/kg every 8 hours.

Meningitis in pediatric patients over 3 months of age:

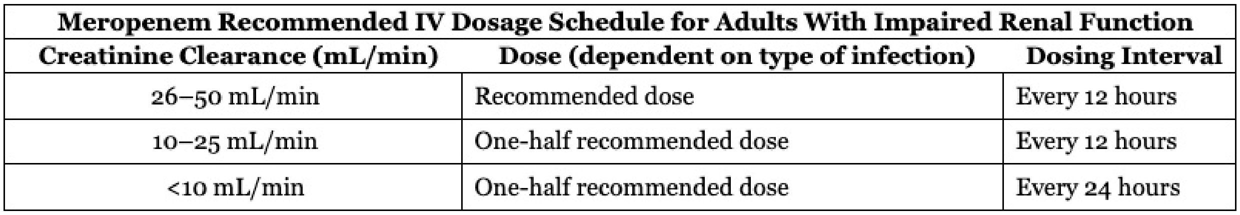
40 mg/kg every 8 hours. Maximum single dose every 8 hours is 2 Gm.

Febrile neutropenia in pediatric patients 3 months of age and older and less than 50 kg (unlabeled):

20 mg/kg every 8 hours. Maximum single dose is 1 Gm.

DOSE ADJUSTMENTS

Reduced dose required if CrCl is less than 51 mL/min based on the following chart.



Meropenem Recommended IV Dosage Schedule for Adults With Impaired Renal Function

Creatinine Clearance (mL/min)	Dose (dependent on type of infection)	Dosing Interval
26–50 mL/min	Recommended dose	Every 12 hours
10–25 mL/min	One-half recommended dose	Every 12 hours
<10 mL/min	One-half recommended dose	Every 24 hours

Consult package insert or front matter of this text for formula to convert SCr to CrCl. ■ No dose adjustment necessary in impaired hepatic function. ■ Reduced dose may be required in the elderly based on decreased renal function. ■ Information is inadequate for use in patients on hemodialysis or peritoneal dialysis. ■ No experience in pediatric patients with renal impairment.

DILUTION

Injection:

Reconstitute each 500 mg with 10 mL SWFI (1 Gm with 20 mL). Yields 50 mg/mL. Shake to dissolve and let stand until clear. May be given as an IV injection or further diluted with **compatible** infusion solutions (see Infusion and Compatibility).

Infusion:

Available as a premixed solution ready for infusion and as infusion vials that may be directly reconstituted with a **compatible** solution and then infused. Concentration may range from 1 to 20 mg/mL. Do not use flexible container in series connections.

Storage:

Store unopened vials (dry powder) at RT (20° to 25° C [68° to 77° F]). Use of freshly prepared solutions preferred. Injection vials reconstituted with SWFI for bolus administration (up to 50 mg/mL) may be stored for up to 3 hours at up to 25° C (77° F) or for 13 hours at up to 5° C (41° F). Solutions prepared for infusion with NS (concentrations ranging from 1 to 20 mg/mL) may be stored for 1 hour at up to 25° C (77° F) or for 15 hours at up to 5° C (41° F). Solutions prepared for infusion with D5W (concentrations ranging from 1 to 20 mg/mL) should be used immediately. Do not freeze.

COMPATIBILITY

Manufacturer states, "Meropenem should not be mixed or physically added to solutions containing other drugs; **compatibility** not established."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection in adults and pediatric patients over 3 months of age:

A single dose (up to 1 Gm [20 mL] after dilution) over 3 to 5 minutes. (Limited safety data are available to support the administration of 40 mg/kg [up to a maximum of 2 Gm] bolus dose.)

Intermittent infusion in adults and pediatric patients over 3 months of age:

A single dose over 15 to 30 minutes.

Intermittent infusion in pediatric patients under 3 months of age:

A single dose over 30 minutes.

Extended infusion (unlabeled):

0.5 to 2 Gm over 3 hours every 8 hours.

ACTIONS

A synthetic, broad-spectrum, carbapenem antibiotic. Bactericidal to selected gramnegative, gram-positive, and anaerobic organisms. Bactericidal activity results from the inhibition of cell wall synthesis. Readily penetrates the cell wall of susceptible organisms to reach penicillin-binding protein targets. Has significant stability to hydrolysis by penicillinases and cephalosporinases produced by gram-positive and gram-negative bacteria. Peak plasma concentrations reached by the end of an infusion. Penetrates well into most body fluids and tissues, including cerebrospinal fluid. Peak fluid and tissue concentrations reached in 0.5 to 1.5 hours. Minimal protein binding. Elimination half-life averages 1 hour in adults, 1.5 hours in pediatric patients age 3 months to 2 years, and 2.7 hours in infants under 3 months of age. 70% recovered as unchanged drug in urine within 12 hours. Not yet known if it crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Indicated as single-agent therapy for treatment of the specific infections caused by susceptible organisms. Is useful as presumptive therapy in the indicated infections before identification of the causative organism because of its broad spectrum of activity. ■ Treatment of complicated intra-abdominal infections (e.g., complicated appendicitis, peritonitis) in adults and pediatric patients. ■ Treatment of complicated skin and skin structure infections in adults and pediatric patients 3 months of age and older. ■ Treatment of bacterial meningitis in pediatric patients 3 months of age and older. Meropenem has been found to be effective in eliminating concurrent bacteremia in association with bacterial meningitis.

Unlabeled uses:

Empiric anti-infective therapy in febrile neutropenic patients. ■ Meningitis in adults. ■ Septicemia. ■ Complicated urinary tract infections caused by susceptible bacteria. ■ Bloodstream infections (gram-negative bacteremia). ■ Respiratory tract infections. ■ Alternate or concomitant therapy in melioidosis caused by *Burkholderia pseudomallei*.

CONTRAINDICATIONS

History of hypersensitivity to meropenem, its components, any other carbapenem antibiotic (e.g., imipenem-cilastatin [Primaxin]), or patients with demonstrated anaphylaxis to beta-lactams; see Precautions.

PRECAUTIONS

Specific sensitivity studies are indicated to determine susceptibility of the causative organism to meropenem. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, meropenem should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ May have cross-resistance with strains resistant to other carbapenems (e.g., imipenem-cilastatin [Primaxin]). ■ Localized clusters of infections resulting from carbapenem-resistant bacteria have been reported in some regions. ■ Serious and occasionally fatal hypersensitivity reactions have been reported in patients receiving therapy with beta-lactams (e.g., penicillins, cephalosporins, carbapenems). More likely in patients with a history of sensitivity to multiple allergens; obtain a careful history. Cross-sensitivity is possible. ■ Severe cutaneous adverse reactions (SCAR) such as acute generalized exanthematous pustulosis (AGEP), drug reaction with eosinophilia and systemic symptoms (DRESS), erythema multiforme (EM), Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN) have been reported. ■ Seizures and other adverse CNS reactions have been reported. Occurred most commonly in patients with a history of CNS disorders (e.g., brain lesions, history of seizures) or with bacterial meningitis and/or compromised renal function. Use extreme caution; continue administration of anticonvulsants in patients with known seizure disorders. ■ Use with caution in patients with impaired renal function; thrombocytopenia may occur; see Dose Adjustments. ■ Has the potential for neuromotor impairment (e.g., delirium, headaches, paresthesias, seizures) that can interfere with mental alertness and/or cause motor impairment; see Patient Education. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result.

■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with meropenem. ■ See Drug/Lab Interactions.

Monitor:

Anaphylaxis has been reported. Emergency equipment must always be available. ■ Monitor infusion site for inflammation and/or extravasation. May cause thrombophlebitis. ■ Monitor for S/S of CDAD. ■ Monitor for S/S of severe cutaneous adverse reactions (SCAR). ■ Monitor for S/S of CNS reactions (e.g., focal tremors, myoclonus, seizures); see Antidote. ■ Monitor renal, hepatic, and hemopoietic systems in prolonged therapy. ■ Each 1 Gm contains 3.92 mEq of sodium; monitoring of electrolytes may be indicated. ■ See Drug/Lab Interactions and Side Effects.

Patient Education:

Review all medications with physician. ■ Report any itching, rash, shortness of breath, or twitching sensation immediately. ■ Report any burning, pain, or stinging at injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking meropenem; see Drug/Lab Interactions. ■ May interfere with mental alertness and/or cause motor impairment. Do not operate machinery or drive until tolerance is established.

Maternal/Child:

Safety for use in pregnancy not established; use only if clearly needed. ■ Use caution during breast-feeding; no information is available on the effects of meropenem on the breast-fed infant or on milk production. ■ Safety and effectiveness established for pediatric patients 3 months of age and older with complicated skin and skin structure infections and bacterial meningitis and for pediatric patients of all ages with complicated intra-abdominal infections.

Elderly:

Consider age-related renal impairment; plasma clearance is decreased with decreased renal function; see Dose Adjustments. Monitoring of renal function is suggested. Response is similar to that seen in younger patients; however, greater sensitivity in the elderly cannot be ruled out. See Precautions.

DRUG/LAB INTERACTIONS

Carbapenems may reduce serum **valproic acid** or **divalproex sodium** concentrations to subtherapeutic levels, resulting in a loss of seizure control. Monitor valproic acid levels. Consider alternative antibacterial therapy. If administration of meropenem is necessary, supplemental anticonvulsant therapy should be considered. ■ **Probenecid** inhibits renal excretion and increases serum levels of meropenem, extending its half-life and increasing systemic exposure; coadministration is not recommended. ■ May be synergistic with **aminoglycosides** against some isolates of *Pseudomonas aeruginosa*.

SIDE EFFECTS

Toxicity rate is usually low. ***Pediatric patients:*** The types of clinical adverse effects seen in pediatric patients are similar to those seen in adults. The most commonly reported adverse effects included diarrhea, glossitis, nausea and vomiting, oral moniliasis, and rash (mostly diaper area moniliasis). In neonates and infants under 3 months of age, additional side effects that were reported irrespective of causality were convulsions, hyperbilirubinemia, and vomiting. ***Adults:*** Anemia, constipation, diarrhea, headache, nausea and vomiting, and rash are most common. Apnea, injection site reactions (e.g., edema, inflammation, pain, phlebitis), pruritus, sepsis, and shock also occurred in more than 1% of patients. Many other side effects—including CDAD; hypersensitivity reactions (including anaphylaxis); increases or decreases in hematologic, hepatic, and renal lab tests; neuromotor impairment; seizures; and thrombocytopenia—may occur in fewer than 1% of patients.

Post-Marketing:

Acute generalized exanthematous pustulosis, agranulocytosis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), erythema multiforme, hemolytic anemia, leukopenia, neutropenia, positive direct or indirect Coombs' test, Stevens-Johnson syndrome, and toxic epidermal necrolysis have been reported.

ANTIDOTE

Notify physician of all side effects. Most treated symptomatically. Discontinue immediately if a hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines. Discontinue meropenem immediately if S/S of severe cutaneous adverse reactions (SCAR) appear, and consider an alternative treatment. If focal tremors, myoclonus, or seizures occur, evaluate neurologically, initiate anticonvulsant therapy, and decide whether to decrease or discontinue meropenem. Mild cases of CDAD may respond to discontinuation of meropenem. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Readily removed by hemodialysis.

MEROPENEM AND VABORBACTAM FOR INJECTION

(mer-oh-**PEN**-em va-bor-**BAK**-tam)
Vabomere
Antibacterial
(Carbapenem/beta-lactamase inhibitor)

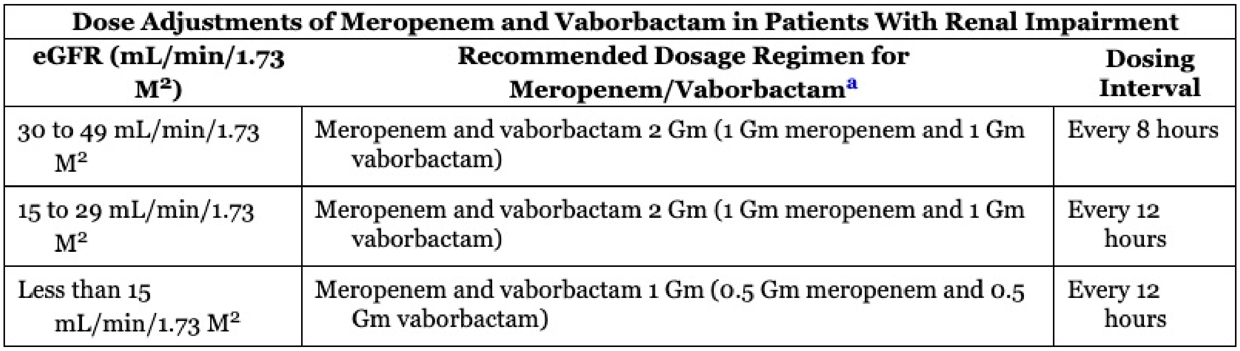
USUAL DOSE

4 Gm (2 Gm meropenem and 2 Gm vaborbactam) every 8 hours as an infusion over 3 hours. An estimated glomerular filtration rate (eGFR) of 50 mL/min/1.73M^2 or greater is required. Duration of treatment is up to 14 days.

DOSE ADJUSTMENTS

Reduced dose may be indicated in the elderly based on age-related renal impairment.

- In patients with renal impairment who have an eGFR less than 50 mL/min/1.73 M^2, adjust dose as outlined in the following chart.



Dose Adjustments of Meropenem and Vaborbactam in Patients With Renal Impairment		
eGFR (mL/min/1.73 M^2)	**Recommended Dosage Regimen for Meropenem/Vaborbactam[a]**	**Dosing Interval**
30 to 49 mL/min/1.73 M^2	Meropenem and vaborbactam 2 Gm (1 Gm meropenem and 1 Gm vaborbactam)	Every 8 hours
15 to 29 mL/min/1.73 M^2	Meropenem and vaborbactam 2 Gm (1 Gm meropenem and 1 Gm vaborbactam)	Every 12 hours
Less than 15 mL/min/1.73 M^2	Meropenem and vaborbactam 1 Gm (0.5 Gm meropenem and 0.5 Gm vaborbactam)	Every 12 hours

[a] In patients maintained on hemodialysis, administer doses adjusted for renal impairment after the hemodialysis session.

DILUTION

Available as a dried powder in single-dose vials containing 2 Gm Vabomere (1 Gm meropenem and 1 Gm vaborbactam). Select the appropriate number of vials as determined from the following chart. To prepare the required dose for IV infusion, reconstitute each vial with 20 mL of NS by withdrawing the 20 mL from an infusion bag of NS. Reconstituted solution is **NOT** for direct injection and has a final volume of approximately 21.3 mL. Concentration of meropenem is approximately 0.05 Gm/mL, and concentration of vaborbactam is approximately 0.05 Gm/mL. Mix gently to dissolve. Immediately withdraw the full or partial reconstituted vial contents from each vial and add it back into the infusion bag of NS previously used as diluent. Solution will be colorless to light yellow.

Preparation of Meropenem and Vaborbactam Doses				
Meropenem and Vaborbactam Dose	**Number of Vials Required**	**Volume to Withdraw From Each Reconstituted Vial**	**Volume of Infusion Bag**	**Final Infusion Concentration of Meropenem and Vaborbactam**
4 Gm (2 Gm and 2 Gm)	2 vials	Entire contents (approximately 21 mL)	250 mL	16 mg/mL
			500 mL	8 mg/mL
			1,000 mL	4 mg/mL
2 Gm (1 Gm and 1 Gm)	1 vial	Entire contents (approximately 21 mL)	125 mL	16 mg/mL
			250 mL	8 mg/mL
			500 mL	4 mg/mL
1 Gm (0.5 Gm and 0.5 Gm)	1 vial	10.5 mL (discard unused portion)	70 mL	14.3 mg/mL
			125 mL	8 mg/mL
			250 mL	4 mg/mL

Filters:

Specific information not available.

Storage:

Store vials at CRT (20° to 25° C [68° to 77° F]). Excursions permitted to 15° to 30° C (59° to 86° F**).** Reconstituted solution must be further diluted immediately. Infusion of the fully diluted solution must be completed within 4 hours if stored at RT or 22 hours if refrigerated at 2° to 8° C (36° to 46° F). Discard unused portions.

COMPATIBILITY

Manufacturer states, “Only **compatible** with NS.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 3 hours.

ACTIONS

Meropenem and vaborbactam is a combination product that contains meropenem (a synthetic carbapenem antibacterial drug) and vaborbactam (a cyclic boronic acid beta-lactamase inhibitor). Bactericidal activity of meropenem results from the inhibition of cell wall synthesis. Meropenem is stable to hydrolysis by most beta-lactamases (including penicillinases and cephalosporinases produced by gram-negative and gram-positive bacteria), with the exception of carbapenem-hydrolyzing beta-lactamases. The vaborbactam component of meropenem and vaborbactam is a beta-lactamase inhibitor that protects meropenem from degradation by certain serine beta-lactamases such as

Klebsiella pneumoniae carbapenemase (KPC). Vaborbactam does not have any antibacterial activity and does not decrease the activity of meropenem. Protein binding of the combination product is minimal. A minor pathway of meropenem elimination is hydrolysis of the beta-lactam ring. Vaborbactam does not undergo metabolism. The elimination half-life is 1.22 hours and 1.68 hours for meropenem and vaborbactam, respectively. Both are primarily excreted in urine. Meropenem is secreted in breast milk.

INDICATIONS AND USES

Treatment of patients 18 years of age and older with complicated urinary tract infections (cUTIs), including pyelonephritis caused by the following susceptible microorganisms: *Escherichia coli, Klebsiella pneumoniae,* and *Enterobacter cloacae* species complex.

CONTRAINDICATIONS

Known hypersensitivity to any components of the product (meropenem and vaborbactam) or to other drugs in the same class, or in patients who have demonstrated anaphylactic reactions to beta-lactam antibacterial drugs.

PRECAUTIONS

For IV infusion only; do not administer as an IV bolus. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, meropenem/vaborbactam should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to meropenem and vaborbactam. ■ No cross-resistance with other classes of antimicrobials has been identified. Some isolates resistant to carbapenems (including meropenem) and to cephalosporins may be susceptible to meropenem and vaborbactam. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions and serious skin reactions have been reported in patients receiving beta-lactam antibacterial drugs. Before initiating therapy, check the history of previous hypersensitivity reactions to penicillins, cephalosporins, other beta-lactam antibacterial drugs, and other allergens. ■ Seizures and other adverse CNS reactions have been reported with meropenem. Occurred most commonly in patients with a history of CNS disorders (e.g., brain lesions, history of seizures) or with bacterial meningitis and/or compromised renal function. Close monitoring, adherence to recommended dosing, and continuation of any prescribed anticonvulsant therapy are recommended in patients at risk for adverse CNS reactions. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with meropenem and vaborbactam. ■ Thrombocytopenia has been observed in patients with renal impairment who have received meropenem; no clinical bleeding has been reported. ■ Has the potential for neuromotor impairment (e.g., delirium, headaches, paresthesias, seizures) that can interfere with mental alertness and/or cause motor impairment; see Patient Education. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ See Drug/Lab Interactions.

Monitor:

Obtain baseline SCr and CBC with differential and platelets; repeat as indicated. ■ Monitor serum creatinine and eGFR at least daily in patients with changing renal function, and adjust dosage accordingly. ■ Monitor for S/S of hypersensitivity reactions (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). Anaphylaxis has occurred; emergency equipment, medications, and supplies must be available. ■ If S/S of CNS reactions occur (e.g., focal tremors, myoclonus, seizures), evaluate neurologically, place on anticonvulsant therapy if not already instituted, and reexamine dose of meropenem and vaborbactam to determine if it should be decreased or discontinued.

Patient Education:

Promptly report any itching, rash, shortness of breath, or twitching sensation. ■ Report any burning, pain, or stinging at injection site. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after meropenem and vaborbactam has been discontinued; may indicate CDAD and require treatment. ■ Patients with a history of seizures should review medication profile with physician before taking meropenem and vaborbactam; see Drug/Lab Interactions. ■ May interfere with mental alertness and/or cause motor impairment. Do not operate machinery or drive until tolerance is established.

Maternal/Child:

Safety for use in pregnancy not established; benefit must justify potential risks to fetus. There is a drug-associated risk of major birth defects or miscarriages with meropenem and vaborbactam in pregnant women. Fetal malformations have been observed in vaborbactam-treated rabbits. ■ Meropenem has been reported to be excreted in human milk. No information available on potential effects of meropenem and vaborbactam on breast-fed infants or on milk production. Consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or effectiveness observed between the elderly and younger patients. Consider age-related renal impairment; plasma clearance is decreased with decreased renal function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Coadministration of carbapenems, including meropenem, to patients receiving **valproic acid** or **divalproex sodium** results in a reduction in valproic acid concentrations. Valproic acid concentrations may drop below the therapeutic range, increasing the risk of breakthrough seizures. Increasing the dose of valproic acid or divalproex sodium may not be sufficient to overcome the interaction. If coadministration is necessary, supplemental anticonvulsant therapy should be considered. ■ **Probenecid** competes with meropenem for active tubular secretion, resulting in increased plasma concentrations of meropenem. Coadministration of probenecid with meropenem and vaborbactam is not recommended.

SIDE EFFECTS

The most common side effects reported are diarrhea, headache, and phlebitis/infusion site reactions. Fever, hypokalemia, increased ALT and AST, and nausea have also been reported, More serious side effects include breakthrough seizures due to drug interaction with valproic acid, CDAD, hypersensitivity reactions, and seizures and other adverse CNS experiences.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Discontinue immediately if a hypersensitivity reaction occurs and treat as appropriate (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids). If focal tremors, myoclonus, or seizures occur, evaluate neurologically, initiate anticonvulsant therapy, and decide whether to decrease or discontinue meropenem and vaborbactam. Mild cases of CDAD may respond to discontinuation of meropenem and vaborbactam. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Removed by hemodialysis.

MESNA

(**MEZ**-nah)
Mesnex, Uromitexan 🍁
Antidote
Chemoprotective agent
pH 7.5 to 8.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Specific testing recommended before each dose of ifosfamide; see Monitor.

Mesna:

Total daily dose is 60% of the ifosfamide dose equally divided into 3 doses. A single dose of mesna equal to 20% of the ifosfamide dose is given at the time of the ifosfamide injection and repeated 4 hours and 8 hours later (e.g., ifosfamide 1.2 Gm/M^2 would require mesna 240 mg/M^2 with the ifosfamide, followed by additional doses of 240 mg/M^2 in 4 hours, and again at 8 hours). The initial mesna dose each day may be mixed with the ifosfamide. Appears to be **compatible**.

Combination of intravenous and oral doses:

At the time of the ifosfamide injection, give a single IV dose of mesna equal to 20% of the ifosfamide dose. At 2 hours and at 6 hours after each dose of ifosfamide, administer mesna tablets PO in a dose equal to 40% of the ifosfamide dose (e.g., ifosfamide 1.2 Gm/M^2 would require mesna 240 mg/M^2 IV with the ifosfamide, followed by an oral mesna dose of 480 mg/M^2 in 2 hours and again at 6 hours). The total daily dose of mesna (IV [20%] and PO [80%] combined) is 100% of the ifosfamide dose; see Monitor. The efficacy and safety of this ratio of IV and oral mesna have not been established as being effective for daily doses of ifosfamide higher than 2 Gm/M².

DOSE ADJUSTMENTS

Dose of mesna must be repeated each day ifosfamide is administered and adjusted with each increase or decrease of the ifosfamide dose so that the ratio of mesna to ifosfamide remains the same.

DILUTION

Each 100 mg (1 mL) must be diluted in a minimum of 4 mL D5W, D5NS, D5/¼NS, D5/⅓NS, D5/½NS, NS, or LR. Desired concentration is 20 mg/mL.

Filters:

Manufacturer's studies measured the potency of ifosfamide in combination with mesna through a 5-micron filter. No significant drug loss for ifosfamide; mesna was not measured.

Storage:

Store at CRT before use. Opened multidose vials may be stored at CRT and used for up to 8 days. Diluted solutions are stable for 24 hours at 25° C (77° F).

COMPATIBILITY

Manufacturer states, "Do not mix mesna injection with cyclophosphamide carboplatin, cisplatin, epirubicin, and nitrogen mustard. The benzyl alcohol contained in mesna injection can reduce the stability of ifosfamide. Ifosfamide and mesna may be mixed in the same bag provided the final concentration of ifosfamide does not exceed 50 mg/mL. Higher concentrations of ifosfamide may not be compatible with mesna and may reduce the stability of ifosfamide."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over a minimum of 1 minute given as a single agent. Administer at rate for ifosfamide if given together. Another source recommends administering as an infusion over 15 to 30 minutes or as a continuous infusion maintained for 12 to 24 hours after completion of the ifosfamide infusion.

ACTIONS

A detoxifying agent. Reacts chemically with urotoxic ifosfamide metabolites to detoxify them and inhibit hemorrhagic cystitis. Is distributed to total body water (plasma, extracellular fluid, and intracellular water). Rapidly metabolized in the plasma to its major metabolite mesna disulfide (dimesna). Half-life is 0.36 hours. Excreted in the urine as mesna and dimesna.

INDICATIONS AND USES

A prophylactic agent used to reduce the incidence of hemorrhagic cystitis caused by ifosfamide.

Unlabeled uses:

May reduce the incidence of hemorrhagic cystitis caused by cyclophosphamide.

CONTRAINDICATIONS

Hypersensitivity to mesna or any of the excipients.

PRECAUTIONS

Hypersensitivity reactions ranging from mild to anaphylaxis have been reported. May occur after the first dose or after several months of exposure. ■ Dermatologic toxicity, including drug rash with eosinophilia and systemic symptoms (DRESS), Stevens-Johnson syndrome (SJS), or toxic epidermal necrolysis (TEN), has been reported. Other skin and mucosal reactions characterized by angioedema, erythema, periorbital edema, pruritus, rash, stomatitis, and urticaria have also been reported. May occur after the first dose or after several months of exposure. ■ Mesna is a thiol compound. Hypersensitivity reactions to mesna and to amifostine, another thiol compound, have been reported. It is unclear whether patients who experience an adverse reaction to a thiol compound are at increased risk for a hypersensitivity reaction to mesna. Repeated doses are required to maintain adequate levels of mesna in the kidneys and bladder to detoxify urotoxic ifosfamide metabolites. ■ Hemorrhagic cystitis caused by ifosfamide is dose dependent. Mesna is most effective when ifosfamide dose is less than 1.2 $Gm/M^2/24$ hr and is somewhat less effective when ifosfamide dose is 2 to 4 $Gm/M^2/24$ hr. If hematuria develops with appropriate doses of mesna, ifosfamide dose may need to be reduced or discontinued. ■ Does not inhibit any other side effects or toxicities caused by ifosfamide therapy. ■ Not effective in preventing hematuria caused by other conditions (e.g., thrombocytopenia).

Monitor:

Maintain adequate hydration and sufficient urinary output as required for ifosfamide treatment. ■ Before administering each dose of ifosfamide, obtain a morning specimen of urine and test for hematuria. Depending on the severity of the hematuria, dose reduction or discontinuation of ifosfamide may be required. ■ If emesis occurs within 2 hours of taking PO mesna, either repeat the PO dose or administer an IV dose. ■ Monitor for S/S of a hypersensitivity reaction (e.g., acute renal impairment, angioedema, arthralgia, cardiovascular symptoms [hypotension, tachycardia], disseminated intravascular coagulation [DIC], fever, hematologic abnormalities, hypoxia, increased liver enzymes, myalgia, nausea, respiratory distress, urticaria, vomiting). ■ Monitor for S/S of dermatologic toxicity.

Patient Education:

Read FDA-approved patient information. ■ Verify pregnancy status of females of reproductive potential before initiating therapy. Effective contraception required during treatment with mesna in combination with ifosfamide and for at least 6 months after the last dose. ■ Advise males with female partners of reproductive potential to use effective contraception during treatment with mesna in combination with ifosfamide and for at least 3 months after the last dose. ■ Drink at least one to two liters of liquid daily. ■ Report pink or red urine immediately. Mesna does not prevent hemorrhagic cystitis in all patients and does not prevent or alleviate any of the other adverse reactions associated with ifosfamide. ■ Take mesna at prescribed times. Report emesis within 2 hours of taking PO mesna. ■ Promptly report any S/S of a hypersensitivity or dermatologic reaction.

Maternal/Child:

Mesna is used in combination with ifosfamide or other cytotoxic agents. Ifosfamide can cause fetal harm when administered to a pregnant woman; see ifosfamide prescribing information for use during pregnancy and lactation. Use during pregnancy only if benefits clearly outweigh risks. ■ Avoid breast-feeding during treatment and for 1 week after the last dose of mesna or ifosfamide. ■ Multidose vial contains benzyl alcohol. Serious adverse reactions, including fatal reactions and the “gasping syndrome,” have occurred in premature neonates and low-birth-weight infants who have received benzyl alcohol. Do not use in neonates or infants.

Elderly:

Dosing should be cautious; however, the ratio of ifosfamide to mesna should remain the same.

DRUG/LAB INTERACTIONS

No clinical drug interactions studies have been conducted. May interfere with several laboratory studies. May cause a false-positive reaction for **urinary ketones.** If a red-violet color develops, glacial acetic acid returns the coloring to violet. ■ May cause a false-negative test for **enzymatic CPK activity**. ■ May cause a false-positive test for **urinary ascorbic acid**.

SIDE EFFECTS

The most common adverse reactions (greater than 10%) when mesna is given with ifosfamide are abdominal pain, alopecia, anemia, anorexia, asthenia, constipation, diarrhea, fatigue, fever, granulocytopenia, headache, leukopenia, nausea, somnolence thrombocytopenia, and vomiting. Less frequently reported reactions include anxiety, back pain, chest pain, confusion, coughing, dehydration, dizziness, dyspepsia, dyspnea, edema, flushing, hematuria, hypersensitivity reactions, hypokalemia, hypotension, injection site reactions, insomnia, pain, pallor, pneumonia, sweating, tachycardia.

Post-Marketing:

Convulsions, dysgeusia, hemoptysis, hepatitis, hypertension.

Overdose:

Diarrhea, fever, hypersensitivity reactions (including asthma exacerbation), flushing, mild hypotension, rash, shortness of breath, and vomiting.

ANTIDOTE

No specific antidote. Keep physician informed of all side effects. Discontinue mesna and provide supportive care at the first S/S of a significant hypersensitivity or dermatologic reaction. Resuscitate as necessary.

METHADONE HYDROCHLORIDE BBW

(**METH**-ah-dohn hy-droh-**KLOR**-eyed)
Dolophine
Opioid analgesic (agonist)
Narcotic abstinence syndrome suppressant
pH 4.5 to 6.5

USUAL DOSE

Parenteral administration permitted only under specific conditions; see Indications and Precautions.

Methadone has a narrow therapeutic index. Dosing is complex and requires extensive individualization. Extended half-life, potential for prolonged respiratory depressant effects, retention in the liver (prolonging the potential duration of action), and high interpatient variability in absorption, metabolism, and relative analgesic potency must be considered. Steady-state plasma concentrations and full analgesic effects are not attained until at least 3 to 5 days on a given dose and may take longer in some patients.

Treatment of pain:

Individualize dose, taking into account the patient's severity of pain, patient response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient's treatment goals.

Initial analgesic in patients who are not being treated with other opioids and are not tolerant to other opioids:

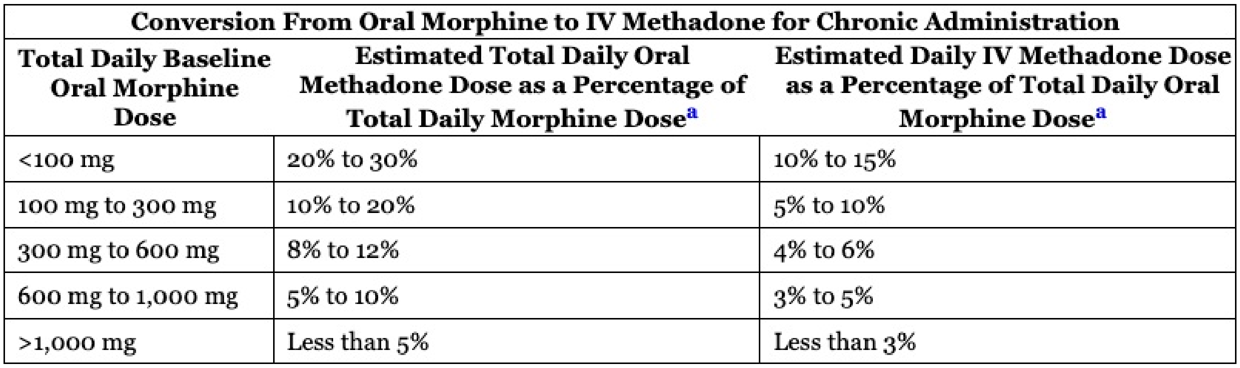
2.5 to 10 mg every 8 to 12 hours. Titrate slowly to effect. More frequent dosing may be required to maintain adequate analgesia; use extreme caution, consider extended half-life, and avoid overdose.

Conversion from oral to parenteral methadone:

Begin with a 2:1 ratio (e.g., 10 mg oral methadone to 5 mg parenteral methadone); see Precautions.

Switching from other chronic opioids to parenteral methadone:

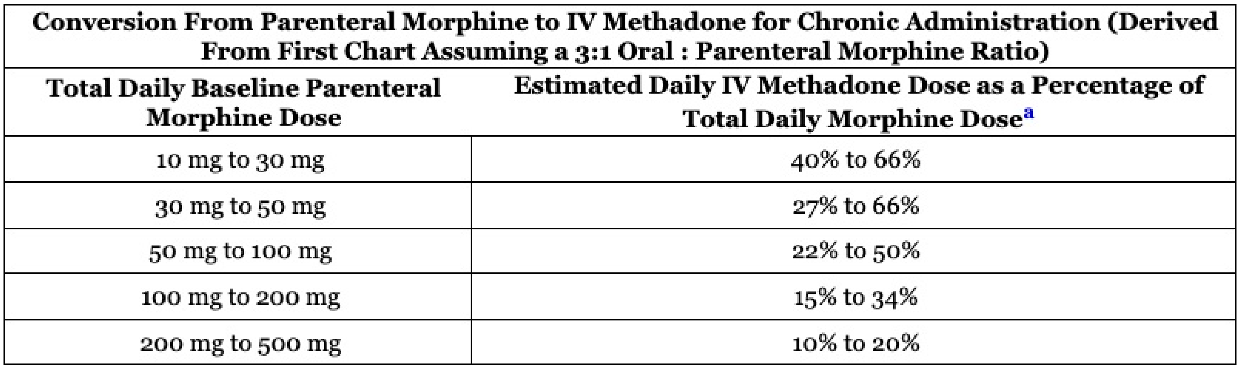
Dose conversion ratios and cross-tolerance are uncertain; deaths have occurred in opioid-tolerant patients during conversion to methadone. Individualize dose based on patient's prior opioid exposure, general medical condition, concomitant medication, and anticipated breakthrough medication use. Titrate to achieve adequate pain relief balanced against tolerability of side effects. Adjust dose and/or dosing interval as necessary. The following two charts are examples of conversions. They are **not** tables of equianalgesic doses and are only for the conversion **from** another opioid **to** methadone. The charts **cannot** be used to convert **from** methadone **to** another opioid.



Conversion From Oral Morphine to IV Methadone for Chronic Administration

Total Daily Baseline Oral Morphine Dose	Estimated Total Daily Oral Methadone Dose as a Percentage of Total Daily Morphine Dose[a]	Estimated Daily IV Methadone Dose as a Percentage of Total Daily Oral Morphine Dose[a]
<100 mg	20% to 30%	10% to 15%
100 mg to 300 mg	10% to 20%	5% to 10%
300 mg to 600 mg	8% to 12%	4% to 6%
600 mg to 1,000 mg	5% to 10%	3% to 5%
>1,000 mg	Less than 5%	Less than 3%

[a] Divide total daily methadone dose as necessary to achieve desired dosing schedule (e.g., divide by 3 for administration every 8 hours).



Conversion From Parenteral Morphine to IV Methadone for Chronic Administration (Derived From First Chart Assuming a 3:1 Oral : Parenteral Morphine Ratio)

Total Daily Baseline Parenteral Morphine Dose	Estimated Daily IV Methadone Dose as a Percentage of Total Daily Morphine Dose[a]
10 mg to 30 mg	40% to 66%
30 mg to 50 mg	27% to 66%
50 mg to 100 mg	22% to 50%
100 mg to 200 mg	15% to 34%
200 mg to 500 mg	10% to 20%

[a] Divide total daily methadone dose as necessary to achieve desired dosing schedule (e.g., divide by 3 for administration every 8 hours).

DOSE ADJUSTMENTS

Lower-end initial doses are indicated in the elderly; consider impaired organ function and concomitant disease or drug therapy. ■ Reduced initial doses are indicated in debilitated patients and in those with severe impaired hepatic or renal function. ■ Clearance may be increased and half-life decreased during pregnancy. Increased doses or shorter intervals between doses may be indicated; see Maternal/Child.

DILUTION

May be given undiluted; however, to facilitate titration, further dilution of each mL with 1 to 5 mL of NS is appropriate. May be given through Y-tube or three-way stopcock of infusion set.

Storage:

A multidose vial; store in carton at CRT protected from light until contents have been used.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an injection over a minimum of several minutes. Titrate according to symptom relief and respiratory rate; side effects may be increased if rate of injection is too rapid.

ACTIONS

A synthetic opioid analgesic with actions similar to those of morphine. Has multiple actions; the most prominent actions involve the CNS and organs composed of smooth muscle. Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways. Principal therapeutic uses are for analgesia and for detoxification or maintenance in opioid addiction. Duration of analgesic action is from 4 to 8 hours. Respiratory depressant effects occur later and persist longer than its peak analgesic effects. With repeated dosing, methadone may be retained in the liver and then slowly released, thereby prolonging the duration of action while plasma concentrations are low. Highly protein bound (85% to 90%). Metabolized in the liver by cytochrome P_{450} enzymes to inactive metabolites. Half-life is prolonged (ranges from 8 to 59 hours). Eliminated by extensive biotransformation followed by renal and fecal elimination. Secreted in saliva, breast milk, amniotic fluid, and umbilical cord plasma.

INDICATIONS AND USES

Management of pain severe enough to require an opioid analgesic and for which alternate treatments are inadequate.

Limitations of use:

Because of the risk of addiction, abuse, and misuse, even at recommended doses, reserve methadone for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated
- Have not provided adequate analgesia or are not expected to provide adequate analgesia

- Temporary treatment in opioid-dependent patients unable to take oral medication.

Limitation of use:

Injectable methadone is not approved for outpatient treatment of opioid dependence. In this patient population, parenteral methadone is to be used only for patients unable to take oral medication, such as hospitalized patients. See Code of Federal Regulations, Title 42, Sec 8.

CONTRAINDICATIONS

Known hypersensitivity to methadone (e.g., anaphylaxis) or any of its components. ■ Significant respiratory depression. ■ Acute or severe bronchial asthma in the absence of resuscitation equipment or in unmonitored settings. ■ In patients with known or suspected of having GI obstruction, including paralytic ileus.

PRECAUTIONS

If the parenteral route is indicated, the IV route is preferred; absorption by the IM or SC routes is unpredictable and may cause local tissue reaction. ■ Methadone exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing methadone, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Serious, life-threatening, or fatal respiratory depression may occur with the use of methadone. The peak respiratory depressant effect occurs later and persists longer than the peak analgesic effect, especially during the initial dosing period. Iatrogenic overdose may occur with short-term use, particularly during treatment initiation and dose titration. Adequate facilities should be available for monitoring and ventilation. An opioid antagonist (e.g., naloxone), resuscitative and intubation equipment, and oxygen should be readily available. ■ Patients tolerant to other opioids may still be sensitive to methadone. This incomplete cross-tolerance makes dose selection difficult when converting to methadone. Deaths have been reported. A high degree of "opioid tolerance" does not eliminate the possibility of methadone toxicity. ■ Prolongation of the QT interval and serious arrhythmias (including torsades de pointes) have been reported. May occur with any dose but appears to be more common with higher dose treatment (greater than 200 mg/day). ■ Use with caution in patients at risk for development of prolonged QT interval (e.g., cardiac conduction abnormalities, cardiac hypertrophy, hypokalemia, hypomagnesemia) and in patients receiving concurrent treatment with other drugs that may induce electrolyte disturbances (e.g., diuretics, laxatives and, rarely, mineralocorticoid hormones) or other drugs that may prolong the QT interval; see Drug/Lab Interactions. ■ Initiate treatment for analgesic therapy in patients with acute or chronic pain only if benefits outweigh the increased risk of QT prolongation with high doses. ■ Use extreme caution in patients with potential respiratory insufficiency (e.g., conditions accompanied by hypoxia or hypercapnia or decreased respiratory reserve [e.g., asthma, COPD, pulmonary disease or cor pulmonale, severe obesity, sleep apnea syndrome, myxedema, kyphoscoliosis, CNS depression, or coma]). Usual doses may decrease respiratory drive and simultaneously increase airway resistance, resulting in apnea. Consider use of nonopioid analgesics. If methadone is required, administer at lowest effective dose under close medical supervision. ■ Cases of serotonin syndrome have been reported during concomitant use of methadone with serotonergic drugs. ■ Cases of adrenal insufficiency have been reported with opioid use, more often after more than 1 month of use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried, because some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ May cause severe hypotension, including orthostatic hypotension and syncope, in ambulatory patients or in any patient whose ability to maintain blood pressure has been compromised by depleted blood volume or concomitant administration of drugs that can cause hypotension (e.g., anesthetics, phenothiazines). In patients with circulatory shock, methadone-induced vasodilation may further reduce cardiac output and blood pressure. Use should be avoided. ■ Use with caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause increased $P\text{CO}_2$, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. Avoid use in patients with impaired consciousness or coma. ■ Use with caution in patients with biliary tract disease, including acute pancreatitis; may cause spasm of the sphincter of Oddi and diminish biliary and pancreatic secretions. ■ May increase the frequency of seizures in patients with a convulsive disorder and may induce or aggravate seizures in some clinical settings. ■ Use caution in elderly or debilitated patients; in patients known to be sensitive to CNS depressants, such as those with cardiovascular, pulmonary, renal, or hepatic disease; and in patients with comorbid conditions or concomitant medications that may predispose to dysrhythmia; see Dose Adjustments and Drug/Lab Interactions. ■ Patients with impaired hepatic function may be at increased risk for accumulating methadone after multiple dosing. ■ Because of their opioid tolerance, patients receiving maintenance doses may require increased or more frequent doses of opioids to treat physical trauma, postoperative pain, or other acute pain. ■ Do not abruptly discontinue methadone in a patient who is physically dependent; dose must be tapered gradually.

Monitor:

Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. Oxygen, controlled ventilation equipment, and naloxone must always be available. ■ Monitor vital signs and oxygenation and observe patient frequently. ■ Assess baseline pain, reassess after administration of methadone, and adjust dose or interval as required. Keep patient supine; orthostatic hypotension and fainting may occur; monitor closely during ambulation. ■ Uncontrolled pain causes sleep deprivation, decreases pain threshold, and increases pain. When pain is finally controlled, expect the patient to sleep more until recovered from sleep deprivation. ■ Closely monitor patients with risk factors for development of a prolonged QT interval, patients with a history of cardiac conduction abnormalities, and patients taking medications that affect cardiac conduction for changes in cardiac rhythm during initiation and titration of methadone. Assess for modifiable risk factors (e.g., drugs with cardiac effects, drugs that may cause electrolyte abnormalities, or drugs that may inhibit the metabolism of methadone); see Drug/Lab Interactions. Consider alternate therapies for pain management. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for increasing intracranial pressure and signs of sedation and respiratory depression. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Laxatives with or without stool softeners will be required to avoid constipation and fecal impaction, especially with increased doses and extended use. Maintain adequate hydration. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Promptly report dizziness, light-headedness, palpitations, or syncope; may indicate a need for ECG monitoring. ■ Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam (Valium)]). Review all medications for possible interactions. ■ May cause blurred vision, dizziness, or drowsiness; use caution in tasks that require alertness. ■ Request assistance with ambulation. ■ Promptly report unrelieved pain or unacceptable side effects. Seek medical attention if breathing difficulties develop. ■ Promptly report S/S of serotonin syndrome. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended. ■ Advise patient of the risk of neonatal opioid withdrawal syndrome (NOWS) so that appropriate planning for management of the neonate can occur; see Maternal/Child.

Maternal/Child:

Potential benefit should justify potential risk to fetus. Consider risk versus benefit for each indication; see prescribing information for further discussion. ■ Total body clearance is increased during pregnancy, and half-life is decreased (during 2nd and 3rd trimesters). May lead to withdrawal symptoms. Increases in dose or dosing at more frequent intervals may be indicated. ■ Not recommended for use in labor and delivery because of long duration of action and increased probability of respiratory depression in the newborn. ■ NOWS is an expected and treatable outcome of methadone use during pregnancy. NOWS may be life threatening if not recognized and treated. See literature for treatment protocols. The balance between the risks of NOWS and the benefits of maternal methadone use may differ based on the risks associated with the mother's underlying condition, pain, or addiction. Untreated opioid addiction often results in continued or relapsing illicit opioid use and is associated with poor pregnancy outcomes (e.g., low birth weight, preterm birth, and fetal death). NOWS can result from in utero exposure to opioids, regardless of the source. ■ Infants born to women treated with methadone during pregnancy may experience respiratory depression (consider methadone's long duration of action). Signs of withdrawal usually occur in the first days after birth and may be observed up to 2 to 4 weeks after delivery. Withdrawal signs include abnormal sleep pattern; hyperactive reflexes; increased respiratory rate; increased stools; irritability and excessive, high-pitched crying; tremors; vomiting; and/or failure to gain weight. May have reduced birth weight, length, and/or head circumference and some deficits in psychometric and behavioral tests. ■ Use with caution in breast-feeding. Advise breast-feeding women taking methadone to monitor the infant for increased drowsiness and breathing difficulties. Women who are breast-feeding should wean gradually to prevent withdrawal symptoms in their infants. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established. ■ See Drug/Lab Interactions.

Elderly:

Dosing should be cautious; see Dose Adjustments. ■ Differences in response compared with younger adults not identified but may have increased sensitivity. Respiratory depression is the chief risk for elderly patients. ■ See Precautions.

DRUG/LAB INTERACTIONS

Concomitant use of methadone with **benzodiazepines** (e.g., diazepam [Valium], midazolam [Versed]) and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required, and monitor patients carefully for S/S of respiratory depression and sedation. In patients being treated for opioid dependence, the FDA has stated that methadone should not be withheld from patients taking benzodiazepines or CNS depressants. The combined use of these drugs increases the risk of serious adverse reactions, including overdose and death; however, the harm caused by untreated opioid addiction usually outweighs these risks. ■ Use caution with concomitant use of methadone and **all cytochrome P_{450} inhibitors** (e.g., macrolide antibiotics [e.g., erythromycin (Erythrocin)], azole antifungals [e.g., fluconazole (Diflucan), ketoconazole (Nizoral)], some selective serotonin reuptake inhibitors [e.g., fluvoxamine (Luvox), sertraline (Zoloft)], and protease inhibitors [e.g., ritonavir (Norvir)]) or when discontinuing any **cytochrome P_{450} inducer** (e.g., rifampin [Rifadin], carbamazepine [Tegretol], phenytoin [Dilantin]) in a methadone-treated patient. May increase plasma concentration of methadone and increase or prolong opioid adverse effects. Monitor patients closely for respiratory depression and sedation, and consider dosage reduction with any changes of concomitant medications that result in an increase in methadone levels. ■ Alternatively, concomitant use of methadone with a **cytochrome P_{450} inducer** or discontinuation of a **cytochrome P_{450} inhibitor** could result in lower than expected methadone plasma concentration and decreased efficacy. An increase in the dose of methadone may be required. ■ Metabolism increased and serum concentrations decreased by **cytochrome P_{450} inducers** (e.g., carbamazepine [Tegretol], phenobarbital [Luminal], phenytoin [Dilantin], rifampin [Rifadin], St. John's wort) and various **antiretroviral drugs** (e.g., abacavir [Ziagen], amprenavir [Agenerase], darunavir/ritonavir combination, efavirenz [Sustiva], nelfinavir [Viracept], nevirapine [Viramune], ritonavir [Norvir], ritonavir/lopinavir combination [Kaletra], saquinavir/ritonavir combination, telaprevir [Incivek], and tipranavir/ritonavir combination). With concurrent administration, the effects of methadone are decreased; monitor for S/S of withdrawal and adjust methadone dose as indicated. ■ Not recommended for concurrent administration with **mixed agonist/antagonists or partial agonists** (e.g., buprenorphine [Buprenex], butorphanol [Stadol], nalbuphine, pentazocine [Talwin]); may precipitate withdrawal symptoms and/or reduce analgesic effect in patients maintained on methadone. ■ May increase serum levels of **desipramine** (Norpramin). ■ May increase AUC of **zidovudine** (AZT, Retrovir) and result in zidovudine toxicity. ■ May decrease AUC and peak levels of **didanosine** (Videx) **and stavudine** (Zerit). ■ Serotonin syndrome has been reported with the concomitant use of opioids, including methadone, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., selegiline [Eldepryl], phenelzine [Nardil], tranylcypromine [Parnate]) and linezolid (Zyvox) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of methadone is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. ■ Use extreme caution with **potentially arrhythmogenic agents** (e.g., Class Ia antiarrhythmic agents [e.g., quinidine, procainamide], Class III antiarrhythmic agents [e.g., amiodarone (Nexterone), sotalol (Betapace)], calcium channel blockers [e.g., diltiazem (Cardizem), verapamil], some neuroleptics [e.g., phenothiazines (e.g., chlorpromazine [Thorazine])], and tricyclic antidepressants [e.g., amitriptyline (Elavil), imipramine (Tofranil)]) or **drugs capable of inducing electrolyte disturbances** (e.g., diuretics). Monitor for cardiac conduction changes. ■ Methadone may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine [Flexeril], orphenadrine [Norflex]), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus.

SIDE EFFECTS

Dizziness, light-headedness, nausea and vomiting, sedation, and sweating occur most frequently. The most serious side effects reported are respiratory depression and, to a lesser degree, systemic hypotension. Respiratory arrest, cardiac arrest, shock, and death have occurred. Other reported side effects include abdominal pain, agitation, anorexia, antidiuretic effect, arrhythmias, asthenia, biliary tract spasm, cardiomyopathy, confusion, constipation, chronic hepatitis, dry mouth, edema, euphoria, flushing, glossitis, headache, heart failure, hypokalemia, hypomagnesemia, hypotension, palpitations, phlebitis, prolonged QT interval, pulmonary edema, pruritus, seizures, skin rashes, syncope, thrombocytopenia (reversible), torsades de pointes, urinary retention or hesitancy, urticaria, visual disturbances.

Overdose:

Bradycardia, cold and clammy skin, constricted pupils, hypotension, respiratory depression (decrease in respiratory rate and/or tidal volume, Cheyne-Stokes respiration, cyanosis), skeletal muscle flaccidity, somnolence progressing to stupor or coma. Apnea, cardiac arrest, circulatory collapse, and death may occur.

ANTIDOTE

Keep physician informed of all side effects; may be treated symptomatically. During prolonged administration (patients on maintenance), side effects usually decrease with time. Lower doses of methadone may be indicated for dizziness, light-headedness, nausea and vomiting, sedation, and sweating. Management of major side effects or overdose requires establishing a patent airway, instituting assisted or controlled ventilation, IV fluids, vasopressors, and other supportive measures as indicated. Do not administer opioid antagonists to physically dependent patients unless clinically significant respiratory or cardiovascular depression occurs. May precipitate an acute withdrawal syndrome. If a decision is made to treat serious respiratory or circulatory depression in a physically dependent patient, administration of the antagonist should begin with care and by titration with smaller than usual doses of the antagonist. Opioid antagonists (e.g., naloxone)have a much shorter duration of action than methadone and may need repeating for up to 48 hours. Continuous monitoring is required. Forced diuresis, peritoneal dialysis, hemodialysis, or charcoal hemoperfusion may not be useful to increase methadone or metabolite elimination; however, urine acidification has been shown to increase renal elimination of methadone.

METHOCARBAMOL

(meth-oh-**KAR**-bah-mohl)
Robaxin
Skeletal muscle relaxant
(central acting)
pH 3.5 to 6

USUAL DOSE

Dose and frequency should be based on severity of condition and on therapeutic response.

1 Gm (10 mL) every 8 hours for no more than 3 days.

If condition persists, may be repeated after a drug-free interval of 48 hours if indicated.

PEDIATRIC DOSE

Not recommended for pediatric patients under 12 years of age except in tetanus.

DILUTION

May be given undiluted, or a single dose may be given as an IV infusion diluted in no more than 250 mL NS or D5W.

Storage:

Store at CRT. Do not refrigerate after dilution.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

300 mg (3 mL) or fraction thereof over 1 minute or longer. Administer IV infusion while in recumbent position and maintain position for 10 to 15 minutes after infusion.

ACTIONS

A CNS depressant with sedative and musculoskeletal relaxant properties. Exact mode of action is unknown. Diminishes skeletal muscle hyperactivity without altering normal muscle tone. Widely distributed throughout the body. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Relief of discomfort from acute, painful musculoskeletal conditions. Adjunctive to other measures (e.g., rest, physical therapy). ■ Treatment of neuromuscular manifestations of tetanus. Adjunctive to other measures (e.g., tetanus antitoxin, fluid and electrolyte replacement).

CONTRAINDICATIONS

Hypersensitivity to methocarbamol, known or suspected renal pathology.

PRECAUTIONS

Blood aspirated into syringe will not mix with medication; an expected phenomenon. ■ Use caution in known or suspected epileptic patients. ■ In patients with impaired renal function, polyethylene glycol 300 (a component of methocarbamol) may increase pre-existing acidosis and urea retention. Usually occurs with amounts greater than the amount contained in this product. ■ Vial stopper contains latex. May cause hypersensitivity reactions when handled by or administered to persons with known or suspected latex sensitivity.

Monitor:

Observe site of injection continuously. A hypertonic solution; extravasation may cause thrombophlebitis or sloughing. ■ Keep patient in recumbent position for at least 15 minutes to avoid postural hypotension. ■ Monitor renal function if duration of treatment is 3 or more days. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol or other CNS depressants. ■ May cause dizziness, drowsiness, and visual disturbances. Request assistance for ambulation. ■ Use caution in any task that requires alertness. ■ Report fever, itching, nasal congestion, or rash promptly. ■ Urine may discolor to very dark green.

Maternal/Child:

Category C: use caution in pregnancy and breast-feeding. Safety for use not established. American Academy of Pediatrics considers it **compatible** with breast-feeding. ■ There have been rare reports of fetal and congenital abnormalities following in utero exposure to methocarbamol.

Elderly:

Males may have sensitivity to anticholinergic effects (e.g., dry mouth, urinary retention). ■ Consider age-related renal impairment; may preclude use.

DRUG/LAB INTERACTIONS

Potentiated by alcohol, **CNS depressants, MAO inhibitors, and phenothiazines**. ■ May inhibit the effect of **pyridostigmine**. Use with caution in patients with myasthenia gravis who are receiving anticholinesterase agents. ■ May interfere with some laboratory tests **(5-HIAA, VMA).**

SIDE EFFECTS

Infrequent but more often associated with too-rapid injection. Blurred vision, conjunctivitis, diplopia, dizziness, drowsiness, fainting, fever, flushing, headache, hypotension, GI upset, light-headedness, metallic taste, muscular incoordination, nasal congestion, nystagmus, pruritus, rash, urticaria, vertigo.

Major:

Anaphylactic reaction, bradycardia, convulsions, pain at injection site, sloughing at injection site, syncope, thrombophlebitis.

ANTIDOTE

Notify the physician of minor side effects. If these side effects progress or major side effects occur, discontinue the drug, notify the physician, and treat symptomatically. Supportive measures may include maintenance of an adequate airway, monitoring of urinary output and VS, and administration of IV fluids. Epinephrine, steroids, and antihistamines should be readily available. Resuscitate as necessary.

METHOTREXATE SODIUM BBW

(meth-oh-**TREKS**-ayt **SO**-dee-um)
Methotrexate PF, MTX
Antineoplastic (antimetabolite)
Antipsoriatic

Antirheumatic
pH 8.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. Verify pregnancy status; see Contraindications.
Many dose limitations based on patient condition, renal and hepatic function, and concomitant drugs or therapies; see Precautions/Monitor. Doses between 100 and 500 mg/M² ***may require*** leucovorin calcium rescue. Doses over 500 mg/M² ***require*** leucovorin calcium rescue; see leucovorin calcium or levoleucovorin (Fusilev) monograph. Part of numerous protocols that change as new advances in antileukemic therapy and other cancers are developed. Selections from those protocols are included in the following text.

Acute lymphoblastic leukemia:

Induction: 3.3 mg/M² in combination with prednisone 60 mg/M². Give daily if tolerated, and continue for up to 8 weeks or until satisfactory response (usually 4 to 6 weeks). Usually given PO.

Maintenance:

Dose individualized; 15 mg/M²/dose administered 2 times weekly IM or PO (a total weekly dose of 30 mg/M²) or 2.5 mg/kg IV every 14 days has been used.

Mycosis fungoides:

5 to 50 mg once weekly in the early stages of disease. Adjust dose or discontinue as indicated by patient response and hematologic monitoring. 15 to 37.5 mg twice weekly may be used in patients who respond poorly to weekly therapy. Usually given PO or IM, but combination chemotherapy regimens, including higher doses of IV methotrexate with leucovorin calcium rescue, have been used in advanced stages of the disease.

Breast cancer (unlabeled):

One regimen administers methotrexate 40 mg/M² on Days 1 and 8 of each cycle. Given in combination with PO cyclophosphamide 100 mg/M² on Days 1 through 14 of each cycle and fluorouracil 600 mg/M² on Days 1 and 8 of each cycle. In patients over 60 years of age, reduce the initial methotrexate dose to 30 mg/M² and the initial fluorouracil dose to 400 mg/M². Repeat monthly (allows a 2-week rest period between cycles) for 6 to 12 cycles.

Psoriasis:

10 to 25 mg once a week until adequate response. Some references suggest an initial test dose of 5 to 10 mg/week before initiating therapy to detect sensitivity to adverse reactions. Sources suggest 30 mg/week as a maximum dose. Use smallest effective dose. Usually given PO or IM. May be used in combination with infliximab; see infliximab monograph.

Osteosarcoma:

One regimen recommends 12 Gm/M^2 as a single dose given as an infusion over 4 hours. Begin the fourth week after surgery and repeat weekly at Weeks 5, 6, 7, 11, 12, 15, 16, 29, 30, 44, and 45. A peak serum concentration of 1,000 micromolars/L at the end of the infusion is desired. Dose may be increased to 15 Gm/M^2 if required. Must be accompanied by leucovorin calcium rescue; see leucovorin calcium or levoleucovorin (Fusilev) monograph. Leucovorin calcium may be given IV or PO; levoleucovorin is IV only. When methotrexate is given in combination with leucovorin rescue, the serum creatinine must be normal, and creatinine clearance must be greater than 60 mL/min before beginning therapy. ***Osteosarcoma also requires combination chemotherapy.*** Protocols vary but may include methotrexate in combination with doxorubicin, with cisplatin, and with the combination of bleomycin, cyclophosphamide, and dactinomycin (BCD regimen). These massive doses are highly individualized and require exacting calculations and constant patient monitoring; see Precautions/Monitor.

PEDIATRIC DOSE

Safety for use in pediatric patients is limited to chemotherapy and in polyarticular-course juvenile rheumatoid arthritis. May contain benzyl alcohol; not recommended for use in neonates. See Maternal/Child.

DOSE ADJUSTMENTS

Manufacturer does not provide information on dose adjustment in patients with impaired renal or hepatic function. However, various recommendations are available in the literature. In patients with impaired hepatic function, one source recommends administering 75% of dose if bilirubin is between 3.1 and 5 or if transaminases are greater than 3 times the ULN; if bilirubin above 5, omit dose. ■ Reduced doses may be required in patients with impaired renal function. Suggested guidelines are to administer 50% of a dose with a CrCl of 10 to 50 mL/min, and avoid use with a CrCl of less than 10 mL/min in adult patients. In pediatric patients, administer 50% of a dose with a CrCl of 10 to 50 mL/min and 30% of a dose with a CrCl of less than 10 mL/min/1.73M^2. ■ Reduced dose may be required in patients with ascites or pleural effusions, in the very young or very elderly, in the debilitated, and in other diseases; see Precautions. ■ Often used with other antineoplastic drugs to achieve tumor remission. ■ See Drug/Lab Interactions.

DILUTION

Specific techniques required; see Precautions.

Available in solution or as a lyophilized powder. Reconstitute powder with D5W or NS. The 1-Gm vial should be reconstituted with 19.4 mL to a concentration of 50 mg/mL. When high-dose methotrexate is administered by IV infusion, the total dose is diluted in D5W. 25 mg/mL is the maximum suggested concentration that can be given IV. Reconstitution of each 5 mg with 2 mL of preservative-free D5W or NS is suggested. Each milliliter equals 2.5 mg of methotrexate. Available in preservative-free solution. Do not use formulations or diluents with preservatives (e.g., bacteriostatic) for high-dose therapy or intrathecal injection. 1-Gm vial available for high-dose use with appropriate dilution. Not usually added to IV solutions when given in smaller doses (less than 100 mg). Discard solution if a precipitate forms. May be given through Y-tube or three-way stopcock of a free-flowing IV.

A single dose may be further diluted with D5W or NS immediately before use as an infusion with higher (100 mg or more) methotrexate doses.

Filters:

No data available from manufacturer. Another source indicates no significant drug loss filtered through a nylon 0.2-micron filter.

Storage:

Store in unopened container at CRT; protect from light. If prepared without a preservative, use immediately. May be stable up to 24 hours with a preservative.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Slow IV push no more than 10 mg/minute.

Infusion:

A single dose equally distributed over 30 minutes to 4 hours or as prescribed by protocol.

ACTIONS

An antimetabolite and folic acid antagonist. Inhibits dihydrofolic acid reductase. Cell cycle–specific for the S phase. It interferes with DNA synthesis, repair, and cellular replication. Rapidly proliferating tissues are more sensitive to this effect. Widely distributed and is approximately 50% protein bound. Undergoes some hepatic and intracellular metabolism. Half-life is dose dependent and is 3 to 10 hours in patients receiving low-dose antineoplastic therapy and 8 to 15 hours in patients receiving high-dose methotrexate therapy. 80% to 90% of the administered dose is excreted unchanged in the urine within 24 hours. Clearance rates decrease with higher doses. Does not cross blood-brain barrier. Secreted in breast milk.

INDICATIONS AND USES

Used for life-threatening neoplastic disease alone or in combination with other anticancer agents in the treatment of acute lymphocytic leukemia, breast cancer, epidermal tumors of the head and neck, small-cell and squamous cell lung cancer, non-Hodgkin lymphoma, advanced mycosis fungoides (cutaneous T-cell lymphoma). ■

Severe, recalcitrant disabling psoriasis or rheumatoid arthritis unresponsive to other treatment. Diagnosis of psoriasis should be established by biopsy and/or dermatology consultation before use. ■ To prolong relapse-free survival in patients with nonmetastatic osteosarcoma who have undergone surgical resection or amputation of the primary tumor. Given as a high-dose regimen with leucovorin rescue in combination with other chemotherapeutic agents. ■ Given PO or IM for early-stage mycosis fungoides, trophoblastic diseases (gestation choriocarcinoma, chorioadenoma destruens, and hydatidiform mole), polyarticular-course juvenile rheumatoid arthritis, rheumatoid arthritis, and other diagnoses, and given intrathecally for treatment and prophylaxis of meningeal leukemia.

Unlabeled uses:

Treatment of bladder and testicular cancer. Treatment of soft tissue sarcomas and CNS tumors. Management of Crohn's disease and ectopic pregnancy and prevention of acute graft-versus-host disease. High-dose regimens for neoplastic diseases other than osteosarcoma are investigational, and therapeutic efficacy is not established.

CONTRAINDICATIONS

Hypersensitivity to methotrexate; breast-feeding mothers. Contraindicated in pregnant females with psoriasis or rheumatoid arthritis and should be used during pregnancy for treatment of neoplastic diseases only when the potential benefit outweighs the risk to the fetus. Contraindicated in psoriasis or rheumatoid arthritis patients with immunodeficiency syndromes, pre-existing blood dyscrasias (e.g., bone marrow hypoplasia, leukopenia, thrombocytopenia, significant anemia), alcoholism, alcoholic liver disease, or other chronic liver disease.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Methotrexate should be used only in life-threatening neoplastic diseases or in patients with psoriasis or rheumatoid arthritis with severe, recalcitrant, disabling disease that is not responsive to other forms of therapy. ■ Deaths have been reported with methotrexate use in the treatment of malignancy, psoriasis, and rheumatoid arthritis. ■ Methotrexate elimination is reduced in patients with impaired renal function, ascites, or pleural effusions. Careful monitoring, dose reduction and, in some cases, discontinuation of therapy are required; consider evacuating excess fluid from ascites and pleural effusions before treatment if possible. ■ Methotrexate can suppress hematopoiesis, causing anemia, aplastic anemia, pancytopenia, leukopenia, neutropenia, and/or thrombocytopenia. ■ Serious and sometimes fatal bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant use of methotrexate (usually high doses) and some NSAIDs; see Drug/Lab Interactions. ■ Leukoencephalopathy has been reported in patients who have received both IV methotrexate and craniospinal irradiation. ■ A transient stroke-like encephalopathy has been reported with high-dose methotrexate therapy. Symptoms may include confusion, hemiparesis, transient blindness, seizures, and coma. ■ Methotrexate-induced lung disease, including acute or chronic interstitial pneumonitis, may occur at any time, may occur even with low doses, and has been fatal. Patients may present with fever, dry cough, dyspnea, hypoxemia, and an infiltrate on chest x-ray. May require interruption of therapy and is not always fully reversible. ■ Severe skin reactions can occur at any time and have been fatal. ■ Transient elevations in liver enzymes may occur early during treatment. Chronic hepatotoxicity (fibrosis and cirrhosis) occurs more frequently with prolonged use and a total dose of at least 1.5 Gm. Persistent abnormalities in liver function tests and/or depression of serum albumin may be indicators of serious liver toxicity. Has resulted in deaths; see Monitor. ■ Use with extreme caution in patients with ascites, bone marrow suppression, folate deficiency, GI obstruction, impaired renal or liver function, infection, peptic ulcer, pleural effusion, or ulcerative colitis; in debilitated patients; and in the very young or very elderly. ■ Diarrhea and ulcerative stomatitis will require interrupting therapy; otherwise hemorrhagic enteritis and death from intestinal perforation may occur. ■ Tumor lysis syndrome may occur, and S/S include hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure. Prevent or alleviate tumor lysis syndrome with appropriate supportive and pharmacologic measures; see Monitor. ■ Potentially fatal opportunistic infections, especially *Pneumocystis jiroveci* pneumonia, may occur. ■ Risk of soft tissue necrosis and osteonecrosis may be increased with concomitant use of methotrexate and radiotherapy. ■ May cause renal damage that may lead to acute renal failure. Nonreversible oliguric renal failure is likely to develop in patients who experience delayed early methotrexate elimination. ■ Malignant lymphomas have been reported. May occur in patients receiving low-dose methotrexate and may not require cytotoxic treatment; discontinue methotrexate first and initiate appropriate treatment if the lymphoma does not regress. ■ Use caution when administering high-dose methotrexate to patients receiving proton pump inhibitors. ■ Use caution when administering methotrexate after a recent history of nitrous oxide administration. ■ Lesions of psoriasis may be aggravated by concomitant exposure to UV radiation. ■ Radiation dermatitis and sunburn may be “recalled” by methotrexate use. ■ See Drug Interactions.

Monitor:

CBC with differential and platelet counts, chest x-ray, and renal and liver function tests before, during, and after therapy are essential to comprehensive treatment. ■ Close patient observation is mandatory. Course of therapy is not repeated until all signs of toxicity from the previous course subside. ■ Monitor closely for bone marrow, liver, lung, kidney, and skin toxicities. ■ Nadir of leukocyte and platelet count usually occurs after 7 to 10 days, with recovery 7 days later. ■ Liver biopsy, pulmonary studies, and bone marrow studies may be indicated in high-dose or long-term therapy. ■ Monitor renal function closely; verify by measurement of serum methotrexate and CrCl levels; see Precautions. Maintain continuing adequate hydration and urine alkalinization. ■ Prevention and treatment of hyperuricemia due to tumor lysis syndrome may be accomplished with adequate hydration and, if necessary, uric acid–lowering drugs (e.g., allopurinol). ■ Monitor serum methotrexate levels. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Profound granulocytopenia and fever should be evaluated immediately and usually requires parenteral broad-spectrum antibiotic therapy. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ ***Administration of high-dose methotrexate*** requires the following: a WBC count greater than 1,500/mm^3, neutrophil count greater than 200/mm^3, platelet count greater than 75,000/mm^3, serum bilirubin less than 1.2 mg/dL, alanine aminotransferase (ALT) level less than 450 units, healing of any mucositis, ascites or pleural effusion must be drained dry, normal SCr, CrCl greater than 60 mL/min, 1 L/M^2 of IV fluid over 6 hours before dosing and 3 L/M^2/day on day of infusion and for 2 days after, alkalinization of urine with sodium bicarbonate to maintain pH above 7, and repeat serum methotrexate and SCr levels at least daily until methotrexate level is below 0.05 micromolar. ■ See Drug/Lab Interactions.

Patient Education:

Avoid pregnancy. Effective contraception recommended for both females and males. Continue for at least 3 months after treatment is complete in male patients and for at least one ovulatory cycle after therapy is complete for female patients. ■ Avoid alcohol and take only prescribed medications. Reactions can be lethal. ■ Side effects such as dizziness and fatigue may interfere with ability to drive or operate machinery. ■ Review early signs and symptoms of toxicity with health care provider. ■ Close follow-up with physician is imperative. ■ See Appendix D, p. 1311.

Maternal/Child:

Category X: avoid pregnancy. Has caused fetal death and congenital anomalies; effective contraception recommended. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients established for cancer chemotherapy and polyarticular-course juvenile rheumatoid arthritis. ■ Serious neurotoxicity (e.g., general or focal seizures) has been reported in patients with acute lymphoblastic leukemia who have been treated with intermediate-dose methotrexate. ■ Administration of formulations containing the preservative benzyl alcohol has been associated with fatal gasping syndrome in neonates. Use preservative-free formulation of methotrexate in neonates.

Elderly:

See Dose Adjustments. Dose selection should be cautious and based on the potential for decreased organ function, decreased folate stores, and concomitant disease or drug therapy. ■ Consider monitoring CrCl and methotrexate levels. ■ Monitor for early signs of hepatic, renal, or bone marrow toxicity. ■ In chronic administration, certain toxicities may be decreased by folate supplementation. ■ Post-marketing experience suggests that the occurrence of bone marrow suppression, thrombocytopenia, and pneumonitis may increase with age.

DRUG/LAB INTERACTIONS

The following drugs may enhance methotrexate toxicity when administered concomitantly: **cyclosporine**, **any hepatotoxic drug** (e.g., azathioprine, retinoids, sulfasalazine), **NSAIDs** (e.g., ibuprofen, ketoprofen, naproxen), **penicillins** (e.g., amoxicillin, nafcillin), **probenecid, salicylates, sulfonamides, phenylbutazone, phenytoin**, **pyrimethamine, trimethoprim** (component of sulfamethoxazole/trimethoprim), **and vancomycin** (given up to 10 days prior to methotrexate); interactions may be life threatening. Monitoring serum levels and/or reduced doses of methotrexate may be indicated or a longer duration of leucovorin calcium rescue may be required. One source suggests delaying administration of aspirin, NSAIDs, and probenecid for 48 hours after larger doses of methotrexate; see Precautions. ■ **NSAIDs** are used in the treatment of rheumatoid arthritis in combination with low doses of methotrexate (e.g., 7.5 to 15 mg/week). Do not administer NSAIDs before or concomitantly with high doses of methotrexate (e.g., treatment of osteosarcoma); deaths from severe hematologic and GI toxicity have been reported. ■ Use caution if high-dose methotrexate is administered in combination with **nephrotoxic chemotherapy agents** (e.g., cisplatin). ■ Concurrent use of methotrexate (primarily at high dose) with **some proton pump inhibitors** such as esomeprazole, omeprazole, and pantoprazole may cause prolonged elevation of serum levels of methotrexate and its metabolite, hydroxymethotrexate, leading to toxicity. Discontinue several days before methotrexate administration. Consider an H_2 antagonist. ■ **Doxycycline** may increase toxicity of methotrexate in high-dose regimens. ■ **Vitamins with folic acid** or its derivatives may inhibit the antifolate effects of methotrexate, decreasing effectiveness. ■ Use of **nitrous oxide anesthesia** results in the potential for increased toxicity such as myelosuppression, neurotoxicity, and stomatitis. Avoid concomitant administration with methotrexate. ■ May increase serum levels of **mercaptopurine**; dose adjustment may be required. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ **Procarbazine** may increase nephrotoxicity of methotrexate. Allow 72 hours between last dose of procarbazine and first dose of methotrexate. ■ Monitor for signs of increased bone marrow suppression with **sulfonamides** (e.g., sulfisoxazole, SMZ-TMP), **bone marrow–suppressing agents** (e.g., antineoplastics), **and radiation therapy.** May also cause SMZ-TMP-induced megaloblastic anemia. ■ May decrease **theophylline** clearance and increase serum levels; monitor theophylline serum levels with concurrent use. ■ **Urinary alkalinizers** increase renal excretion and may reduce effectiveness.

SIDE EFFECTS

Toxicity usually dose related. Death can occur from average doses, high doses, drug interactions (e.g., NSAIDs), bone marrow toxicity, GI toxicity, hepatic toxicity, pulmonary toxicity, and/or severe skin reactions. Abdominal distress, chills, decreased resistance to infection, dizziness, fatigue, fever, leukopenia, malaise, nausea, and ulcerative stomatitis occur most frequently. Other side effects reported include abortion (spontaneous), acne, acute hepatitis, agranulocytosis, alopecia, alveolitis, anaphylaxis, anemia, anorexia, aplastic anemia, azotemia, blurred vision, chronic fibrosis and cirrhosis, convulsions, COPD, cystitis, decreased serum albumin, defective oogenesis or spermatogenesis, diabetes, diarrhea, drowsiness, ecchymosis, enteritis, eosinophilia, erythema multiforme, erythematous rashes, exfoliative dermatitis, fetal defects or death, furunculosis, GI ulceration and bleeding, gingivitis, gynecomastia, headache, hematemesis, hematuria, hemiparesis, hepatic failure, hepatotoxicity, hypotension, infertility, interstitial pneumonitis, liver enzyme elevations, lymphadenopathy and lymphoproliferative disorders, melena (passage of dark, tarry stools), menstrual dysfunction, nephropathy (severe), neutropenia, oligospermia (transient), opportunistic infections (e.g., cryptococcosis, cytomegalovirus infection, disseminated *H. simplex*, herpes zoster, histoplasmosis, *H. simplex* hepatitis, nocardiosis, *Pneumocystis jiroveci* pneumonia, pneumonia, sepsis [including fatal]), pancreatitis, pancytopenia, paresis, pericardial effusion, pericarditis, pharyngitis, photosensitivity, pigmentary changes, proteinuria, pruritus, pseudomembranous colitis, renal failure, respiratory failure, respiratory fibrosis, serious visual changes of unknown etiology, skin necrosis, skin ulceration, speech impairment (aphasia, dysarthria), Stevens-Johnson syndrome, stomatitis, stress fracture, suppressed hematopoiesis (blood cell formation), telangiectasia, thrombocytopenia, thromboembolic events (e.g., arterial thrombosis, cerebral thrombosis, deep vein thrombosis, pulmonary embolus, retinal vein thrombosis, thrombophlebitis), sudden death, toxic epidermal necrolysis, transient blindness, tumor lysis syndrome, urticaria, vaginal discharge, vomiting. Many other rarer side effects, including anaphylactoid reactions, have been reported.

ANTIDOTE

Discontinue methotrexate and notify the physician of any side effects. **Leucovorin calcium (citrovorum factor, folinic acid)** may be given PO, IM, or IV promptly to counteract inadvertent overdose. Leucovorin calcium is also indicated as a planned rescue mechanism for large doses of methotrexate required to treat some malignancies. Doses equal to dose of methotrexate are frequently required. Should be given within 1 hour in overdose, 24 hours in rescue. See specific process for overdose and for rescue for high-dose MTX in leucovorin calcium monograph. Doses up to 150 mg or 100 mg/M^2 every 3 hours may be required if SCr is 50% or greater than baseline measurement before methotrexate administration. Serum methotrexate must come down to below 0.05 micromolar. Continuing hydration and urinary alkalinization are mandatory to prevent precipitation in renal tubules. Monitor fluid and electrolyte status until serum methotrexate has fallen to less than 0.05 micromolar and renal failure has resolved. Glucarpidase (Voraxaze), an antidote indicated for the treatment of toxic methotrexate concentration in patients with delayed methotrexate clearance due to impaired renal function, may also be used. If glucarpidase is used, do not administer leucovorin within 2 hours before or after a dose of glucarpidase because leucovorin is a substrate for glucarpidase; see glucarpidase monograph. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Death may occur from the progression of most of these side effects. Symptomatic and supportive therapy is indicated. Charcoal hemoperfusion may be helpful, and/or acute intermittent hemodialysis with a high-flux dialyzer may be used to counteract toxicity or inadvertent overdose.

METHOXY POLYETHYLENE GLYCOL-EPOETIN BETA BBW

(meth-**OX**-ee pol-ee-**ETH**-il-een **GLYE**-kol ee-**POH**-ee-tin **BAY**-tuh)
Mircera
Colony-stimulating factor
Erythropoietin-stimulating agent (ESA)
Hematopoietic agent
pH 6 to 6.4

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. In all situations, the rate of hemoglobin increase is dose dependent and varies among patients. Availability of iron stores, baseline hemoglobin, and concurrent medical problems affect the rate and extent of response. Evaluate iron status in all patients before and during treatment and maintain iron repletion. Correct or exclude other causes of anemia (e.g., vitamin deficiency, metabolic or chronic inflammatory conditions, bleeding). In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 Gm/dL. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion; see Precautions and Monitor. In adult patients, may be given by IV or SC injection or into the venous line at the end of a dialysis session. The IV route is recommended in patients undergoing hemodialysis; see Precautions.

Patients with chronic kidney disease (CKD) on dialysis:

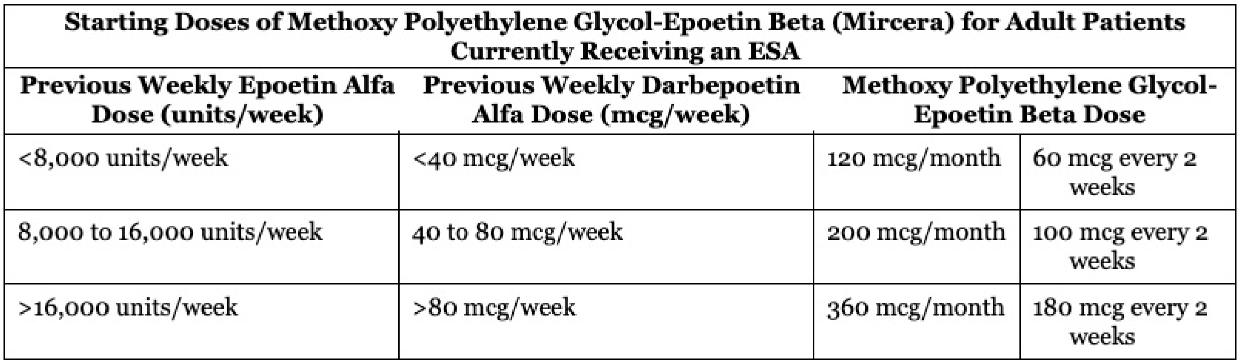
0.6 mcg/kg body weight once every 2 weeks. Initiate treatment when the hemoglobin level is less than 10 Gm/dL. If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt dose of methoxy polyethylene glycol-epoetin beta. Once the hemoglobin has been stabilized, methoxy polyethylene glycol-epoetin beta may be administered once monthly using a dose that is twice that of the every-2-week dose. Titrate as necessary; see Dose Adjustments.

Patients with CKD not on dialysis:

0.6 mcg/kg body weight once every 2 weeks. Consider initiating methoxy polyethylene glycol-epoetin beta treatment only when the hemoglobin level is less than 10 Gm/dL and the following two considerations apply: (1) the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion, and (2) reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal. If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of methoxy polyethylene glycol-epoetin beta. Once the hemoglobin has been stabilized, methoxy polyethylene glycol-epoetin beta may be administered once monthly using a dose that is twice that of the every-2-week dose. Titrate as necessary; see Dose Adjustments.

Conversion from epoetin alfa or darbepoetin alfa to methoxy polyethylene glycol-epoetin beta in patients with CKD:

Base the dose of methoxy polyethylene glycol-epoetin beta on the total weekly ESA dose at the time of conversion from the other ESA according to the following chart.



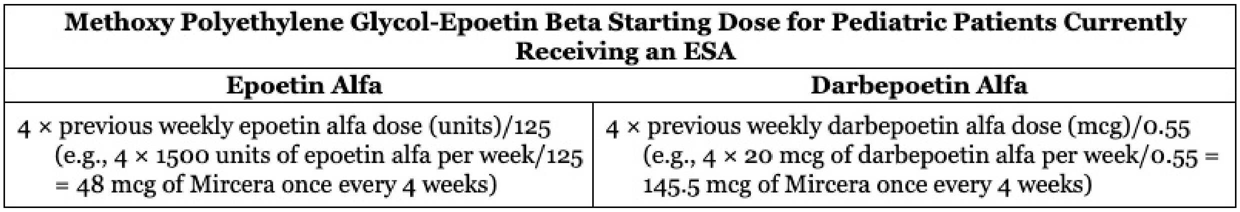
Starting Doses of Methoxy Polyethylene Glycol-Epoetin Beta (Mircera) for Adult Patients Currently Receiving an ESA

Previous Weekly Epoetin Alfa Dose (units/week)	Previous Weekly Darbepoetin Alfa Dose (mcg/week)	Methoxy Polyethylene Glycol-Epoetin Beta Dose	
<8,000 units/week	<40 mcg/week	120 mcg/month	60 mcg every 2 weeks
8,000 to 16,000 units/week	40 to 80 mcg/week	200 mcg/month	100 mcg every 2 weeks
>16,000 units/week	>80 mcg/week	360 mcg/month	180 mcg every 2 weeks

PEDIATRIC DOSE

Pediatric patients with chronic kidney disease (CKD) on dialysis:

Administer methoxy polyethylene glycol-epoetin beta IV once every 4 weeks to patients 5 to 17 years of age whose hemoglobin level has been stabilized by treatment with an ESA. Base the dose of methoxy polyethylene glycol-epoetin beta on the total weekly ESA dose at the time of conversion from the other ESA according to the following chart.



Methoxy Polyethylene Glycol-Epoetin Beta Starting Dose for Pediatric Patients Currently Receiving an ESA	
Epoetin Alfa	**Darbepoetin Alfa**
4 × previous weekly epoetin alfa dose (units)/125 (e.g., 4 × 1500 units of epoetin alfa per week/125 = 48 mcg of Mircera once every 4 weeks)	4 × previous weekly darbepoetin alfa dose (mcg)/0.55 (e.g., 4 × 20 mcg of darbepoetin alfa per week/0.55 = 145.5 mcg of Mircera once every 4 weeks)

DOSE ADJUSTMENTS

Dose adjustment is based on hemoglobin. When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. Dose should be started slowly and adjusted for each patient to achieve and maintain a hemoglobin level sufficient to avoid the need for RBC transfusion. Allow sufficient time before adjusting a dose; increased hemoglobin levels may not be observed for 2 to 6 weeks. ■ Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period), reduce the dose by 25% or more as needed to reduce rapid responses. ■ For patients who do not respond adequately after 4 weeks of therapy (e.g., the hemoglobin has not increased by more than 1 Gm/dL), increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase risks. Discontinue methoxy polyethylene glycol-epoetin beta if responsiveness does not improve.

Patients with CKD on dialysis:

If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of methoxy polyethylene glycol-epoetin beta.

Patients with CKD not on dialysis:

If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of methoxy polyethylene glycol-epoetin beta. ■ See Precautions and Monitor.

DILUTION

Available in numerous concentrations in single-use prefilled syringes; check dose carefully. May be given undiluted as an IV injection. Do not shake. Contains no preservatives. Use only 1 dose per syringe. Do not pool unused portions from the prefilled syringes.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original cartons. Do not shake, and avoid prolonged exposure to light. Do not freeze. May be stored at less than 25° C (77° F) for up to 30 days. Do not use past the expiration date or if it has been frozen or improperly refrigerated.

Filters:

No data available from manufacturer.

COMPATIBILITY

Manufacturers state, "Do not mix with any parenteral solution." One source indicates there may be protein loss from adsorption to PVC containers and tubing.

RATE OF ADMINISTRATION

A single dose as an IV injection over at least 1 minute.

ACTIONS

An erythropoietin receptor activator with greater activity *in vivo* and an increased half-life, in contrast to erythropoietin. Has the same biologic effects as erythropoietin produced naturally by the kidneys. Erythropoietin is a primary growth factor for erythroid development and is released into the bloodstream in response to hypoxia. In responding to hypoxia, erythropoietin interacts with erythroid progenitor cells to increase red cell production. Production of endogenous erythropoietin is impaired in patients with CKD, and erythropoietin deficiency is the primary cause of their anemia. Stimulates bone marrow to produce RBCs, increasing the red cell count and hemoglobin within 7 to 15 days. Normal iron stores are necessary because it steps up RBC production to a rate above what the body usually makes. New cells need iron, which is quickly depleted. Continued therapy will maintain improved RBC levels and decrease the need for transfusions. Terminal half-life is 119 hours. Hemodialysis does not alter serum concentrations.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease (CKD) in:

- Adult patients on dialysis and patients not on dialysis.
- Pediatric patients 5 to 17 years of age on hemodialysis who are converting from another ESA after their hemoglobin level has stabilized with an ESA.

Limitation of use:

Not indicated or recommended for the treatment of anemia due to cancer chemotherapy. A study was terminated early because of significantly more deaths than in patients receiving another ESA. ■ Not indicated or recommended as a substitute for RBC transfusions in patients who require immediate correction of anemia. ■ Has not been shown to improve symptoms, physical functioning, or health-related quality of life. ■ Not approved for the reduction of RBC transfusions in patients scheduled for surgery.

CONTRAINDICATIONS

History of serious or severe hypersensitivity reaction (e.g., anaphylaxis, angioedema, bronchospasm, skin rash, and urticaria) to methoxy polyethylene glycol-epoetin beta. ■ Uncontrolled hypertension. ■ Pure red cell aplasia (PRCA) that begins after treatment with methoxy polyethylene glycol-epoetin beta or other ESA drugs.

PRECAUTIONS

All patients:

May be given IV or SC in adult patients not receiving dialysis. May be given to adult or pediatric dialysis patients into the venous line at the end of the dialysis procedure to eliminate additional venous access. ■ In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered ESAs to target a hemoglobin level of greater than 11 Gm/dL. An increased risk of CHF, venous thromboembolism, and thrombosis of vascular access was also demonstrated when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, an ESA dose, or a dosing strategy that does not increase these risks. Use the lowest ESA dose sufficient to reduce the need for RBC transfusions. ■ Use caution in patients with coexistent CVD and stroke. Patients with CKD and an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ Administration of erythropoiesis-stimulating agents (ESAs) to cancer patients shortened the overall survival time and/or increased the risk of tumor progression or recurrence in clinical studies of patients with breast, cervical, head and neck, lymphoid, and non–small-cell lung malignancies; see Limitation of Use. ■ In controlled clinical trials of patients with cancer, ESAs increased the risk of death and serious adverse cardiovascular reactions, including MI and stroke. ■ Blood pressure may increase during therapy with methoxy polyethylene glycol-epoetin beta. Control hypertension before administration. Hypertensive encephalopathy and/or seizures have been reported; see Monitor. ■ Serious hypersensitivity reactions, including anaphylactic reactions, have been reported. ■ For lack or loss of hemoglobin response to methoxy polyethylene glycol-epoetin beta, initiate a search for causative factors (e.g., bleeding, infection, inflammation, iron deficiency). If typical causes of lack or loss of hemoglobin response are excluded, evaluate for pure red cell aplasia (PRCA). In the absence of PRCA, follow dosing recommendations for management of patients with an insufficient hemoglobin response to therapy; see Dose Adjustments. ■ Not intended for use in anemias caused by iron or folate deficiencies, hemolysis, or GI bleeding or for use in treating symptoms of anemia, including dizziness, fatigue, low energy, poor quality of life, or shortness of breath. ■ In controlled clinical trials, ESAs increased the risk of death in patients undergoing coronary artery bypass graft surgery (CABG) and the risk of deep venous thrombosis (DVT) in patients undergoing orthopedic procedures. ■ Cases of pure red cell aplasia (PRCA) and severe anemia, with or without other cytopenias, in association with neutralizing antibodies to native erythropoietin has been reported. Most often reported in CKD patients receiving ESAs by SC injection. Any patient who develops a sudden loss of response to ESAs accompanied by severe anemia and a low reticulocyte count should be evaluated for the development of neutralizing antibodies to ESAs. Withhold all further doses and obtain serum samples at least a month after the last dose to prevent interference with the assay. Physicians may contact the manufacturer to perform assays for antibodies. ■ Seizures have been reported. ■ Blistering skin exfoliation reactions, including erythema multiforme and Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN), have been reported. ■ Other ESAs include a warning to use caution in patients with porphyria; may exacerbate disease. ■ Other ESAs indicate that safety and efficacy is not established in patients with a known history of an underlying hematologic disorder (e.g., sickle cell anemia, myelodysplastic syndrome, or hypercoagulable disorders).

Monitor:

All patients:

Obtain baseline CBC with differential and platelet counts and monitor at regular intervals. When initiating or adjusting therapy, monitor hemoglobin levels at least weekly until stable, then monitor at least monthly. ■ Normal iron stores are required to support epoetin-stimulated erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 mcg/mL. Monitor before and during therapy. Supplemental iron therapy may be required to increase and maintain transferrin saturation. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, pruritus, skin rash, Stevens-Johnson syndrome/toxic epidermal necrolysis, tachycardia, and urticaria). ■ Hypertension must be controlled before initiation of therapy. Monitor BP frequently and control aggressively; generally rises when hemoglobin or hematocrit is increasing rapidly. Patients may require an increase in antihypertensive therapy and dietary restrictions. Reduce or withhold methoxy polyethylene glycol-epoetin beta if BP is difficult to control. ■ Seizures have occurred. Most occur within the first several months of therapy. Observe BP and monitor for premonitory neurologic symptoms. ■ Monitor patients with pre-existing vascular disease carefully; increase in hemoglobin may precipitate a cerebrovascular accident, transient ischemic attack, or myocardial infarction. ■ Dialysis patients may require adjustment in their dialysis prescription and increased anticoagulation with heparin to prevent clotting of the extracorporeal circuit during hemodialysis. ■ Compliance with dialysis and/or dietary restrictions is mandatory. ■ Monitor fluid and electrolyte balance carefully in patients not receiving dialysis. An improved sense of well-being may mask the need for dialysis.

Patient Education:

Review manufacturer’s medication guide carefully. ■ Increased risk of serious cardiovascular reactions, thromboembolic reactions, stroke, and tumor progression. Promptly report chest pain, pain or swelling in the legs, SOB, increase in BP, dizziness, or loss of consciousness. ■ Risk of seizures, especially during the first several months of therapy. Contact health care provider for new-onset seizures, premonitory symptoms, or change in seizure frequency. Do not drive or operate heavy equipment. ■ Additional instruction (e.g., equipment, techniques) will be required for patients on home dialysis who will self-administer. ■ Stress the importance of compliance with diet, iron, and vitamin (e.g., folic acid, B_{12}) supplementation. ■ Close monitoring of BP and Hgb is imperative. ■ Promptly report S/S of a hypersensitivity reaction. ■ Use in off-label dose regimens or populations increases risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression.

Maternal/Child:

Pregnancy in women with CKD has been associated with adverse outcomes, including hypertension, pre-eclampsia, miscarriage, premature birth, low-birth-weight infants, polyhydramnios, and intrauterine growth restriction. Methoxy polyethylene glycol-epoetin beta may present risk to fetus; consider risk versus benefit. ■ Use caution in nursing mothers and consider risk versus benefit. ■ The safety and effectiveness for the treatment of anemia due to CKD have been established in pediatric patients 5 to 17 years of age on hemodialysis who are converting from another ESA after their hemoglobin level was stabilized with an ESA. The safety and effectiveness for this indication have not been established in patients under 5 years of age. The safety and effectiveness of methoxy polyethylene glycol-epoetin beta have not been established in pediatric patients of any age for subcutaneous administration, for treatment of anemia in patients with CKD on peritoneal dialysis, for treatment of anemia in patients with CKD who are not yet on dialysis, or for patients whose hemoglobin level has not been previously stabilized by treatment with an ESA.

Elderly:

Dose selection should be cautious; consider age-related organ impairment. ■ Differences in response compared with younger adults has not been identified. ■ Monitor blood chemistry and BP carefully due to increased risk of renal and/or cardiovascular complications.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Most commonly reported side effects include diarrhea, hypertension, and nasopharyngitis. Other side effects reported include arteriovenous fistula site complications, arteriovenous fistula thrombosis, back pain, constipation, cough, extremity pain, fluid overload, headache, hypotension, muscle spasm, upper respiratory tract infection, UTI, and vomiting. Serious side effects reported include cardiovascular and thromboembolic events, hypersensitivity reactions, hypertension, increased mortality, pure red cell aplasia, seizures, and tumor progression; see Precautions. Reasons for discontinuing treatment included anemia, concomitant termination of other CKD therapy, coronary artery disease, hypertension, and septic shock.

Post-Marketing:

PCRA and severe anemia (with or without other cytopenias that arise following the development of neutralizing antibodies to erythropoietin), Stevens-Johnson syndrome/toxic epidermal necrolysis.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of an ESA until BP is controlled; hypertension may respond to a reduction in dose or to an increase in antihypertensive therapy. Reduce dose in patients with an increase in hemoglobin over 1 Gm/dL in any 2-week period, if hemoglobin increases to greater than 11 Gm/dL in a CKD patient on dialysis, or if hemoglobin increases to greater than 10 Gm/dL in a CKD patient not yet on dialysis. May need to withhold dose until hemoglobin falls to desired level. Consider phlebotomy in toxicity. Additional heparin may be required during dialysis to prevent clotting. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Permanently discontinue therapy in patients with antibody-mediated anemia. Patients should not be switched to other erythropoietic proteins because antibodies may cross-react. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary. Not removed by hemodialysis.

METHYLENE BLUE BBW

(**METH**-ih-leen **BLOO**)
ProvayBlue
Antidote
pH 3 to 4.5

ProvayBlue is a methylene blue formulation approved for use by the FDA. Other formulations of methylene blue carry a warning that they have not been found to be safe and effective by the FDA.

USUAL DOSE

Adult and pediatric patients:

1 mg/kg IV over 5 to 30 minutes. If the methemoglobin level remains greater than 30% or if clinical signs and symptoms persist, a repeat dose of 1 mg/kg may be given 1 hour after the first dose. If methemoglobinemia does not resolve after 2 doses, consider alternative treatment options.

DOSE ADJUSTMENTS

Use of the lowest number of doses needed to achieve a response is recommended in the elderly, in patients with impaired renal or hepatic function, and in all patients to avoid hemolytic anemia.

DILUTION

Available in single-dose 10-mL ampules containing 50 mg of methylene blue (5 mg/mL). May be given undiluted; however, it is a hypotonic solution and may be diluted in 50 mL of D5W to avoid local pain, particularly when used for pediatric patients.

Filters:

Specific information not available.

Storage:

Store at CRT in original package to protect from light. Do not refrigerate or freeze. Use the diluted solution immediately after preparation. Discard any unused product.

COMPATIBILITY

Manufacturer states, “Do not mix with NS; chloride reduces the solubility of methylene blue.”

RATE OF ADMINISTRATION

Ensure patent venous access before administration. Administer a single dose as an injection or as an infusion evenly distributed over 5 to 30 minutes.

ACTIONS

A water-soluble thiazine dye and oxidation-reduction agent. Low concentrations of methylene blue promote conversion of methemoglobin to hemoglobin. Methemoglobin is toxic and gives the blood a chocolate-brown color; it does not carry oxygen. Methylene blue is first converted to leuco methylene blue (LMB). The LMB molecule then reduces the ferric iron of methemoglobin to the ferrous state of normal hemoglobin. Highly protein bound (94%). Metabolized in the liver. Half-life is approximately 24 hours. 40% excreted unchanged in urine.

INDICATIONS AND USES

Treatment of adult and pediatric patients with acquired methemoglobinemia. Approval was accelerated. Continued approval for this indication may be contingent on verification of clinical benefit in subsequent trials.

CONTRAINDICATIONS

Severe hypersensitivity to methylene blue or any other thiazine dye. ■ Patients with glucose-6-phosphate dehydrogenase deficiency (G6PD) due to the risk of hemolytic anemia.

PRECAUTIONS

For IV use only; do not administer SC or IM. ■ May cause serious or fatal serotonergic syndrome when used in combination with serotonergic drugs. Avoid concomitant use with selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), and monoamine oxidase inhibitors; see Monitor and Drug/Lab Interactions. ■ Hypersensitivity reactions, including anaphylaxis, have been reported with methylene blue class products. ■ Methemoglobinemia may not resolve or may rebound after response to treatment in patients with methemoglobinemia due to aryl amines such as aniline or sulfa drugs such as dapsone. If no response after 2 doses or if rebound occurs after a response, consider additional treatment options. ■ Hemolysis has occurred during treatment. ■ Oxygen saturation readings by pulse oximetry may be underestimated; if required, obtain by arterial blood sample. ■ A fall in the Bispectral Index (BIS) has been reported with methylene blue class products. If methylene blue is administered during surgery, use alternative methods for assessing the depth of anesthesia. ■ Methylene blue is a blue dye that passes freely into urine and may interfere with interpretation of any urine test that relies on a blue indicator (e.g., dipstick test for leukocyte esterase). ■ Risk of toxicity or potential drug interactions may be increased in patients with renal or hepatic impairment.

Monitor:

Monitor VS, ECG, and methemoglobin levels during treatment and through resolution of methemoglobinemia. ■ Monitor for the emergence of serotonin syndrome. S/S may include autonomic instability (e.g., diaphoresis, dizziness, flushing, hyperthermia, labile BP, tachycardia), GI symptoms (e.g., diarrhea, nausea, vomiting), mental status changes (e.g., agitation, coma, delirium, hallucinations), neuromuscular symptoms (e.g., hyperreflexia, incoordination, myoclonus, rigidity, tremor), and/or seizures. If symptoms of serotonin syndrome occur, discontinue methylene blue and initiate supportive treatment. ■ Monitor for S/S of a hypersensitivity reaction (e.g., angioedema, bronchospasm, urticaria). ■ Monitor for laboratory S/S of hemolysis (elevated indirect bilirubin, Heinz bodies, low haptoglobin, but the Coombs' test is negative). The onset of anemia may be delayed 1 or more days after treatment. ■ Monitor patients with renal or hepatic impairment for S/S of toxicity and potential drug interactions for an extended period of time following treatment with methylene blue. Clearance of methylene blue is delayed.

Patient Education:

Risk of serotonin syndrome; do not take serotonergic drugs (e.g., medications to treat depression or migraines) within 72 hours after the last dose of methylene blue. Promptly report dizziness, hallucinations, incoordination, nausea, rigidity, seizures, tremor, or tachycardia. ■ Promptly report S/S of a hypersensitivity reaction (e.g., light-headedness, rash, urticaria, tightness of the chest, wheezing). ■ May cause confusion, disturbances in vision, and dizziness. Avoid driving or engaging in hazardous occupations or activities such as operating heavy or potentially dangerous machinery until symptoms resolve. ■ Phototoxicity may occur; take protective measures against exposure to light. ■ May cause a blue discoloration of the skin and body fluids. ■ See Maternal/Child.

Maternal/Child:

May cause fetal harm; advise pregnant women of potential risk to fetus. Intra-amniotic injection of methylene blue hours to days before birth can result in hyperbilirubinemia, hemolytic anemia, skin staining, methemoglobinemia, respiratory distress, and photosensitivity in the newborn. Following administration of methylene blue to a pregnant woman at term, observe the newborn for these adverse reactions and institute supportive care as needed. ■ Discontinue breast-feeding during and for up to 8 days after treatment with methylene blue. ■ Safety and effectiveness for use in pediatric patients have been established.

Elderly:

Response similar to younger patients. ■ Risk of adverse reactions may be increased in patients with impaired renal function; use of lowest number of doses recommended.

DRUG/LAB INTERACTIONS

May interact with any drug that acts as a **serotonin reuptake inhibitor, including serotonin reuptake inhibitors** (SSRIs) (e.g., citalopram [Celexa], escitalopram [Lexapro], fluoxetine [Prozac], fluvoxamine [Luvox], paroxetine [Paxil], sertraline [Zoloft], vilazodone [Viibryd]), **serotonin norepinephrine reuptake inhibitors** (SNRIs) (e.g., desvenlafaxine [Pristiq], duloxetine [Cymbalta], venlafaxine [Effexor]), **tricyclic antidepressants (TCAs)** (e.g., clomipramine [Anafranil]), **monoamine oxidase inhibitors** (MAOIs) (e.g., isocarboxazid [Marplan], phenelzine [Nardil], tranylcypromine [Parnate]), **other psychiatric medications** (e.g., buspirone [BuSpar], mirtazapine [Remeron], nefazodone [Serzone], trazodone [Oleptro]), **triptans,** and **ergot alkaloids.** Concomitant use may induce serotonin syndrome and should be avoided. If concomitant use cannot be avoided, choose the lowest possible dose and observe closely for CNS effects for up to 4 hours after administration. ■ Inhibits a range of CYP isozymes in vitro (e.g., 1A2, 2B6, 2C8, 2C9, 2C19, 2D6, and 3A4/5). Interaction could be more pronounced with narrow therapeutic index drugs that are metabolized by one of these enzymes (e.g., alfentanil, cyclosporine [Sandimmune], digoxin [Lanoxin], dihydroergotamine [D.H.E. 45], ergotamine [Ergomar], fentanyl, phenytoin [Dilantin], pimozide [Orap], quinidine, sirolimus [Rapamune], tacrolimus [Prograf], warfarin [Coumadin]). Clinical relevance unknown.

SIDE EFFECTS

Most commonly reported side effects include chromaturia, dizziness, dysgeusia, feeling hot, headache, hyperhidrosis, nausea, pain in extremity, and skin discoloration. Numerous other side effects have been reported. Hypersensitivity reactions, including anaphylaxis, hemolytic anemia, and serotonin syndrome with concomitant use of serotonergic drugs are the most serious side effects. Interference with in vivo monitoring devices (e.g., pulse oximetry, measurement of anesthesia depth), effects on ability to drive and operate machinery, interference with laboratory tests (e.g., blue urine), and lack of effectiveness have also been reported.

Overdose:

Abdominal pain; apprehension; blue staining of the urine, skin, and mucous membranes; chest tightness; confusion; death; dizziness; dyspnea; ECG changes (T-wave flattening or inversion); headache; hyperbilirubinemia; hypotension; mild methemoglobinemia (up to 7%); mydriasis; nausea; paresthesia; pericordial pain; reduced oxygenation; severe intravascular hemolysis; tachypnea; tachycardia; tremor;

vomiting; and wheezing.

ANTIDOTE

Keep physician informed of all side effects; most will be treated symptomatically. Discontinue methylene blue if a severe hypersensitivity reaction occurs and treat immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Discontinue methylene blue, initiate supportive treatment, and consider alternative treatments if severe hemolysis occurs or if symptoms of serotonin syndrome appear. Anemia may require red blood cell transfusions. In the case of overdose, maintain the patient under observation until S/S have resolved; monitor for cardiopulmonary, hematologic, and neurologic toxicities; and institute supportive measures as necessary. Resuscitate as necessary.

METHYLERGONOVINE MALEATE

(meth-ill-er-**GON**-oh-veen **MAL**-ee-ayt)
Methergine
Uterine stimulant (oxytocic)
pH 2.7 to 3.5

USUAL DOSE

1 mL (0.2 mg); repeat doses should be IM or PO.

DILUTION

Check expiration date on vial; methylergonovine deteriorates with age. May be given undiluted. Some clinicians recommend dilution with 5 mL of NS. Do not add to IV solutions. May be given through Y-tube or three-way stopcock of infusion set.

Filters:

No data available from manufacturer; suggests following hospital protocol for filtering from ampules.

Storage:

Store in refrigerator (2° to 8° C [36° to 46° F]); protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

0.2 mg or fraction thereof over 1 minute. Too-rapid injection may cause severe nausea and vomiting. See Precautions.

ACTIONS

A semi-synthetic ergot alkaloid used for prevention and control of postpartum hemorrhage. An oxytocic. It exerts a direct stimulation on the smooth muscle of the uterus. Increases tone, rate, and amplitude of rhythmic contractions. Shortens third-stage labor and reduces blood loss. In therapeutic doses the prolonged initial contraction of the uterus is followed by periods of relaxation and contraction. May also produce vasoconstriction, increase CVP and BP, and may rarely produce peripheral ischemia. Effective within minutes. Half-life approximately 3.4 hours. It is probably metabolized in the liver and excreted in feces. Secreted in breast milk.

INDICATIONS AND USES

Routine management of uterine atony, hemorrhage, and subinvolution of the uterus following delivery of the placenta. ■ Control of uterine hemorrhage in the second stage of labor following delivery of the anterior shoulder.

CONTRAINDICATIONS

Hypersensitivity, hypertension, pregnancy before third stage of labor (delivery of the placenta) except as stated in Indications, toxemia. ■ Contraindicated for concomitant use with potent CYP3A4 inhibitors and azole antifungals; see Drug/Lab Interactions.

PRECAUTIONS

IV administration is for emergency use only. IM or oral routes are preferred and should be used after the initial IV dose. ■ IV use may induce hypertension and/or CVA. Give slowly and monitor BP. ■ Use caution in presence of sepsis, obliterative vascular disease, and hepatic or renal disease. ■ Patients with coronary artery disease or risk factors for coronary artery disease (e.g., diabetes, high cholesterol, obesity, smoking) may be more susceptible to developing myocardial ischemia and infarction associated with methylergonovine-induced vasospasm. ■ Use with caution during the second stage of labor. The necessity for manual removal of a retained placenta should occur rarely with proper technique and adequate allowance of time for a spontaneous separation. ■ Avoid intra-arterial or periarterial injection. ■ See Contraindications.

Monitor:

Monitor BP. ■ Observe for signs of excessive bleeding. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: see Contraindications and Precautions. ■ Avoid breast-feeding during treatment with methylergonovine. Wait at least 12 hours after administration of the last dose before initiating or resuming breast-feeding. Milk secreted during this period should be discarded. May be given orally with caution during breast-feeding for up to 1 week after delivery. ■ Inadvertent administration of methylergonovine to newborn infants resulting in convulsions, cyanosis, oliguria, and respiratory depression has been reported. Methylergonovine should be stored separately from medications intended for neonatal administration (e.g., vitamin K, hepatitis B vaccine). ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Difference in safety and effectiveness compared to younger adults not observed. ■ If used in the elderly, dose selection should be cautious.

DRUG/LAB INTERACTIONS

Severe hypertension and cerebrovascular accidents can result with **ephedrine and other vasopressors.** Hydralazine IV will reduce this hypertension. ■ ***Do not administer with potent CYP3A4 inhibitors,*** such as **macrolide antibiotics** (e.g., erythromycin, clarithromycin), **HIV protease inhibitors** (e.g., indinavir, nelfinavir, ritonavir), **reverse transcriptase inhibitors** (e.g., delavirdine), **or azole antifungals** (e.g., fluconazole). Serum levels increased. Elevated levels of ergot alkaloids can cause ergotism (i.e., risk for vasospasm potentially leading to cerebral ischemia and/or ischemia of the extremities). ■ May be used cautiously with **less potent CYP3A4 inhibitors** (e.g., saquinavir, fluconazole, grapefruit juice, fluoxetine, fluvoxamine, zileuton, and clotrimazole). ■ **Strong CYP3A4 inducers** (e.g., rifampin, nevirapine) may decrease effectiveness of methylergonovine. ■ **Anesthetics** may reduce oxytocic effect of methylergonovine. ■ Produces vasoconstriction and can be expected to reduce the effect of **antianginal drugs** (e.g., nitroglycerin). ■ Concomitant use with **other ergot alkaloids or prostaglandins** will produce additive effects. Use caution.

SIDE EFFECTS

Rare in therapeutic doses but may include the following:

Abdominal pain (caused by uterine contractions), bradycardia, chest pain (temporary), coronary artery spasm, diaphoresis, diarrhea, dilated pupils, dizziness, dyspnea, hallucinations, headache, hematuria, hypersensitivity reactions, hypertension (transient), hypotension, leg cramps, MI, nasal congestion, nausea, palpitations, rash, seizures, tachycardia, thrombophlebitis, tinnitus, vasoconstriction, vasospasm, vomiting, water intoxication, weakness.

Overdose:

Cerebrovascular accident, coma, convulsions, hypertension (followed by hypotension in severe cases), hypothermia, numbness, oliguria, palpitations, respiratory depression, severe nausea and vomiting, tachycardia, tingling of the extremities.

Post-Marketing:

Angina, atrioventricular block, cerebrovascular accident, paresthesia, ventricular fibrillation, ventricular tachycardia.

ANTIDOTE

Discontinue the drug immediately at the onset of any side effect and notify the physician. Most side effects are transient unless there is severe toxicity and will be treated symptomatically. Use antiemetics for nausea and vomiting. Treat seizures with anticonvulsants. Maintain adequate pulmonary ventilation, especially if convulsions or coma develop. Correct hypotension with pressor drugs. Apply warmth to extremities to control peripheral vasospasm.

METHYLPREDNISOLONE SODIUM SUCCINATE

(meth-ill-pred-**NISS**-oh-lohn **SO**-dee-um **SUK**-sih-nayt)
A-Methapred, Solu-Medrol
Hormone (corticosteroid)
Anti-inflammatory
pH 7 to 8

USUAL DOSE

Pretreatment:

Patient selection and baseline studies indicated; see Precautions and Monitor.

Use the lowest possible dose to control the condition being treated. When reduction in dose is possible, the reduction should be gradual.

Methylprednisone:

Average initial dose range is 10 to 40 mg. May be repeated every 4 to 6 hours as necessary. IV methylprednisolone is usually given in an emergency situation or when oral dosing is not feasible. Larger doses may be justified by patient condition. Repeat until adequate response, then decrease dose as indicated. Total dose usually does not exceed 1.5 Gm/24 hr, but higher doses have been used in acute, life-threatening situations. High-dose treatment is used until patient condition stabilizes, usually no longer than 48 to 72 hours.

High-dose therapy:

30 mg/kg IV over at least 30 minutes. May repeat every 4 to 6 hours for 48 hours.

Anti-inflammatory:

10 to 40 mg. May be repeated every 4 to 6 hours as necessary.

Acute spinal cord injury high-dose therapy (unlabeled):

Spinal cord injury must be less than 8 hours old. The earlier methylprednisolone therapy begins, the better the results. ***Loading dose:*** 30 mg/kg of a specifically diluted solution (see Dilution) evenly distributed over 15 minutes. Maintain IV line with standard IV fluids for 45 minutes, then begin a ***maintenance dose*** of 5.4 mg/kg/hr for 23 hours. Discontinue 24 hours after loading dose initiated.

Status asthmaticus or asthma exacerbations:

Newer asthma guidelines recommend 40 to 80 mg/day in 1 to 2 divided doses until peak expiratory flow is 70% of predicted or personal best.

Acute exacerbation of multiple sclerosis:

160 mg as a single dose each day for 7 days. Follow with 64 mg every other day for 1 month. Another source recommends an unlabeled dose of 1,000 mg IV daily for 3 to 7

days.

Pneumocystis jiroveci pneumonia (unlabeled):

Initiate within 24 to 72 hours of initial antibiotic PCP therapy. 30 mg twice daily for 5 days. Follow with 30 mg once daily for 5 days (Days 6 to 10). Then reduce to 15 mg once daily for 11 days (Days 11 to 21) or until antibiotic regimen is complete.

Severe lupus nephritis (unlabeled):

0.5 to 1 Gm as an infusion over 1 hour for 3 days. Follow with long-term prednisolone oral therapy.

PEDIATRIC DOSE

See Maternal/Child. Dose should be based on the severity of the disease and the patient response rather than on strict adherence to a dose indicated by age, weight, or body surface area.

Anti-inflammatory/immunosuppressive:

The range of initial doses is 0.11 to 1.6 mg/kg/day (3.2 to 48 mg/M^2/day) in 3 to 4 divided doses (0.0275 to 0.4 mg/kg every 6 hours or 0.036 to 0.53 mg/kg every 8 hours, or 0.8 to 12 mg/M^2 every 6 hours or 1.06 to 16 mg/M^2 every 8 hours). Another source recommends 0.5 to 1.7 mg/kg/day in divided doses every 6 to 12 hours (0.125 to 0.425 mg/kg every 6 hours, or 0.25 to 0.85 mg/kg every 12 hours).

Status asthmaticus or asthma exacerbation:

Newer asthma guidelines recommend 1 to 2 mg/kg/day in single or divided doses (maximum 60 mg/day) until peak expiratory flow is 80% of predicted or personal best. Dose should not be less than 0.5 mg/kg every 24 hours. Usually requires 3 to 10 days of treatment. Another source recommends 2 mg/kg as a ***loading*** dose. ***Maintain*** with 0.5 to 1 mg/kg every 6 hours for up to 5 days.

Severe lupus nephritis (unlabeled):

30 mg/kg every other day for 6 doses. Follow with long-term prednisolone oral therapy.

DOSE ADJUSTMENTS

Use lowest possible dose required to control condition being treated. When dose reduction is possible, decrease dose gradually while monitoring for S/S of disease exacerbation. ■ Because complications of treatment with glucocorticoids are dependent on dose and duration of therapy, a risk/benefit decision must be made for each patient regarding dose and duration of treatment and whether daily or intermittent therapy should be used. ■ Clearance of corticosteroids is decreased in patients with hypothyroidism and increased in patients with hyperthyroidism. Dose adjustment may be required. ■ See Precautions and Drug/Lab Interactions.

DILUTION

Available in Act-O-Vials containing 40 mg, 125 mg, 500 mg, and 1,000 mg. Each vial has an appropriate amount of diluent. Reconstitute by pressing down on the plastic activator, allowing the diluent into the lower chamber. Agitate gently. Remove the plastic tab covering the center of the stopper and sterilize the stopper with a suitable germicide. Using sterile technique, insert a needle through the center of the rubber stopper to withdraw diluted solution. To be diluted only with diluent supplied in Act-O-Vial. Also available in vials, including a 2,000-mg dose. Should be diluted with accompanying diluent or BWFI with benzyl alcohol. May be given as direct IV, as an infusion, or further diluted in desired amounts of D5W, D5NS, or NS.

Acute spinal cord injury loading and maintenance doses:

Each 1-Gm vial must be diluted to 16 mL with bacteriostatic water to maintain potency and avoid precipitation (62.5 mg/mL). Further dilute in D5W, D5NS, or NS with an amount to facilitate dose of 5.4 mg/kg/hr. (Example for a patient weighing 50 kg: [50 kg × 5.4 mg/hr = 270 mg/hr. 270 mg/hr × 23 hours = 6,210 mg total dose]. With a total dose of 6,210 mg at 62.5 mg/mL, you will have 99.36 [100] mL of reconstituted methylprednisolone. Add an additional 100 mL diluent to achieve 31.25 mg/mL. 270 mg/hr is the desired dose for this patient. 270 mg/hr divided by 31.25 mg/mL [strength of solution] equals 8.6. Administer at 8.6 mL/hr to achieve desired dose over 23 hours.)

Storage:

Protect from light. Store both unreconstituted product and solution at RT (20° to 25° C [68° to 77° F]). Use solution within 48 hours of mixing. Heat sensitive; do not autoclave.

COMPATIBILITY

Manufacturer states, “Because of possible physical **incompatibilities,** should not be diluted or mixed with other solutions.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

May give as a slow IV injection; rates range from over several minutes to at least 5 minutes for doses less than or equal to 250 mg. Also refer to institution-specific polices. When higher doses are needed, administer up to 30 mg/kg over 30 minutes or more. Too-rapid administration of high doses (greater than 500 mg administered over a period of less than 10 minutes) may precipitate cardiac arrhythmia and sudden death. Direct IV administration of lower doses (10 to 40 mg) is usually the route of choice in emergency situations and eliminates the possibility of overloading the patient with IV fluids. May be given as an ***infusion*** in its own diluent. At the discretion of the physician, a continuous infusion may be given, properly diluted in D5W, NS, D5NS, or other **compatible** IV solution over a specified time.

Acute spinal cord injury:

See Usual Dose and Dilution.

ACTIONS

A glucocorticoid steroid with potent anti-inflammatory actions. A synthetic adrenocortical steroid. Glucocorticoids cause profound and varied metabolic effects. They are primarily used for their potent anti-inflammatory effects on different organ systems and their ability to modify the body's immune response. Methylprednisolone has a greater anti-inflammatory potency than prednisolone and less tendency to cause excessive potassium and calcium excretion and sodium and water retention. Has five times the potency of hydrocortisone sodium succinate. Has minimal mineralocorticoid activity. Demonstrable effects are seen within 1 hour of administration. Primarily metabolized in the liver and excreted in the urine. Dose is almost completely excreted after 12 hours. Therefore it must be dosed every 4 to 6 hours if sustained high blood levels are required. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Includes treatment of allergic states, dermatologic diseases, endocrine disorders, gastrointestinal diseases, hematologic disorders, neoplastic diseases, nervous system disorders, ophthalmic diseases, renal diseases, respiratory diseases, and rheumatic disorders. See prescribing information for a complete list. Used primarily as an anti-inflammatory or immunosuppressant agent. May be used in conjunction with other forms of therapy, such as epinephrine for acute hypersensitivity reactions. Oral therapy should be used when appropriate.

Unlabeled uses:

High-dose therapy as an adjunct to traditional spinal cord injury management; to improve neurologic recovery in an acute (less than 8 hours old) spinal cord injury. ■ Treatment of *Pneumocystis jiroveci* pneumonia as an adjunct to antibiotics.

CONTRAINDICATIONS

Hypersensitivity to any product component, including sulfites; systemic fungal infections. ■ Solu-Medrol 40 mg contains lactose monohydrate and is contraindicated in patients with a known or suspected hypersensitivity to cow's milk or its components or other dairy products. ■ Formulations containing benzyl alcohol are contraindicated in premature infants and for intrathecal administration. ■ Intrathecal administration. ■ IM administration for idiopathic thrombocytopenic purpura.

PRECAUTIONS

Ruling out latent amebiasis or active amebiasis is recommended before initiating corticosteroid therapy in any patient who has spent time in the tropics or has unexplained diarrhea. ■ Not the drug of choice to treat acute adrenocortical insufficiency. ■ Corticosteroids may produce hypothalamic-pituitary-adrenal (HPA) axis suppression, Cushing's syndrome, and hyperglycemia, with resulting glucocorticosteroid insufficiency in patients undergoing chronic or prolonged therapy. To avoid relative adrenocortical insufficiency, do not stop therapy abruptly; taper off. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore hormone therapy should be reinstituted in any situation of stress occurring during that period (e.g., surgery, trauma, infection). If the patient is already receiving steroids, dosage may need to be increased. ■ Formulation may contain benzyl alcohol; see Contraindications and Maternal/Child. ■ Rare instances of anaphylactoid reactions have been reported in patients receiving corticosteroid therapy. ■ Hypersensitivity reactions to cow's milk have been reported; see Contraindications. ■ In one study, an increase in mortality was seen in patients with cranial trauma who had no other clear indication for corticosteroid treatment. High doses of systemic corticosteroids should not be used for treatment of traumatic brain injury. ■ Should not be used in cerebral malaria; no evidence of benefit reported. ■ Use with caution in patients who have had a recent MI. Ventricular free wall rupture has been reported. ■ Prolonged use of corticosteroids may increase susceptibility to infection, reactivate latent infectious diseases, or mask signs of infection; see Contraindications. ■ Corticosteroids should be used with great caution in patients with known or suspected Strongyloides (threadworm) infestation. Corticosteroid-induced immunosuppression may lead to Strongyloides hyperinfection and dissemination with widespread larval migration, often accompanied by severe enterocolitis and potentially fatal gram-negative sepsis. ■ The use of methylprednisolone in patients with active tuberculosis should be restricted to cases of fulminating or disseminated tuberculosis in which the corticosteroid is being used for management of disease in conjunction with an appropriate anti-tuberculosis regimen. ■ If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, reactivation of the disease may occur. Chemoprophylaxis is indicated during prolonged corticosteroid therapy. ■ Infections such as chickenpox and measles can have a more serious or even fatal course in pediatric and adult patients taking corticosteroids. Patients who have not had these diseases should take care to avoid exposure. If exposed, therapy with varicella zoster immune globulin (VZIG) or IVIG may be indicated. If chickenpox develops, treatment with antiviral agents should be considered. ■ Use with caution in patients with systemic sclerosis. An increased incidence of scleroderma renal crisis has been observed with corticosteroids, including methylprednisolone. ■ Use with caution in patients with CHF, hypertension, or renal insufficiency. May affect fluid and electrolyte balance. ■ Steroid-induced liver injury (acute toxic hepatitis) has been reported with high doses of cyclically pulsed IV methylprednisolone (usually for treatment of exacerbations of multiple sclerosis at doses of 1 Gm/day). Recurrence has occurred after rechallenge. ■ Use with caution in patients with thyroid dysfunction; see Dose Adjustments. ■ Use with caution in patients with active or latent peptic ulcers, diverticulitis, fresh intestinal anastomoses, and nonspecific ulcerative colitis. May be at increased risk for perforation. ■ Metabolism of corticosteroids is decreased in patients with cirrhosis; effects may be enhanced. ■ Use with caution in patients at risk for osteoporosis. Corticosteroids decrease bone formation, increase bone resorption, and decrease protein matrix of the bone. May lead to inhibition of bone growth in pediatric patients and the development of osteoporosis at any age. ■ An acute myopathy has been reported with the use of high doses of corticosteroids. Most often seen in patients with disorders of neuromuscular transmission (e.g., myasthenia gravis) or in patients receiving concomitant therapy with neuromuscular blocking drugs (e.g., pancuronium). Myopathy is generalized, may involve ocular and respiratory muscles, and may result in quadriparesis. Clinical improvement following discontinuation of corticosteroids may take weeks to years. ■ May induce psychological changes (e.g., depression, euphoria, insomnia, mood swings, personality changes, psychosis). May aggravate existing emotional instability or psychotic tendencies. ■ Kaposi's sarcoma has been reported in patients receiving corticosteroid therapy, most often for chronic conditions. Clinical improvement has been seen with discontinuation of the corticosteroid. ■ Prolonged use of corticosteroids may produce posterior subcapsular cataracts or glaucoma with possible damage to the optic nerves, and it may enhance the establishment of secondary ocular infections due to bacteria, fungi, or viruses. Use with caution in patients with ocular herpes simplex because of corneal perforation. Should not be used in active ocular herpes simplex.

Monitor:

Monitor electrolytes. May cause sodium retention and potassium and calcium excretion. Dietary salt restriction and potassium supplementation may be necessary. ■ May cause hypertension secondary to fluid and electrolyte disturbances. Monitor BP. ■ Monitor for S/S of infection. May be masked. ■ Patients with latent tuberculosis should be monitored for reactivation of the disease. ■ May increase insulin needs in patients with diabetes. Monitor serum glucose. ■ During prolonged therapy, routine laboratory studies such as urinalysis, 2-hour postprandial blood sugar, BP, body weight assessment, and chest x-ray should be obtained at regular intervals. Upper GI x-rays are suggested for patients with a history of ulcers or significant dyspepsia. ■ May increase intraocular pressure. Periodic ophthalmic exams may be necessary with prolonged treatment. ■ Elevation of creatine kinase may occur with acute myopathy. Monitor if indicated. ■ Monitor for S/S of a hypersensitivity reaction. ■ See Drug/Lab Interactions.

Patient Education:

Report edema, tarry stools, or weight gain promptly. Report anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, or vomiting; may indicate adrenal insufficiency after dose reduction or discontinuing therapy. ■ May mask signs of infection and/or decrease resistance. ■ Diabetics may have increased requirement for insulin or oral hypoglycemics. ■ Avoid immunizations with live virus vaccines. ■ Avoid exposure to measles or chickenpox. Seek immediate medical advice if exposure occurs. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child:

Use with caution during pregnancy; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Infants born to mothers who received corticosteroids during pregnancy should be carefully monitored for signs of hypoadrenalism. ■ May contain benzyl alcohol, which has been associated with a fatal "gasping syndrome" in neonates. ■ Monitor growth and development of pediatric patients receiving prolonged treatment.

Elderly:

Differences in response between the elderly and younger patients have not been identified. Dose selection should be cautious based on the possibility of age-related organ impairment (e.g., bone marrow reserve, renal, hepatic). May be more sensitive to effects.

DRUG/LAB INTERACTIONS

Aminoglutethimide may lead to a loss of corticosteroid-induced adrenal suppression. ■ Metabolism increased and effects reduced by **hepatic enzyme–inducing agents** (e.g., barbiturates, carbamazepine, phenytoin, rifampin); dose adjustments may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B or potassium-depleting diuretics** (e.g., thiazides, furosemide, ethacrynic acid). Monitor potassium levels and cardiac function. ■ Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May decrease effectiveness of **potassium supplements;** monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease sodium excretion and diuretic effects of diuretics. ■ Increased activity of both **cyclosporine** and **corticosteroids** may occur when used concurrently. Convulsions have been reported with concurrent use. ■ Clearance decreased and effects increased with **estrogens, oral contraceptives, triazole antifungals** (e.g., itraconazole), **and macrolide antibiotics** (e.g., azithromycin, clarithromycin, erythromycin). ■ **Ketoconazole** can significantly decrease the metabolism of certain corticosteroids and lead to an increased risk of corticosteroid side effects. ■ **Cholestyramine** may increase the clearance of corticosteroids. ■ Coadministration of **aprepitant** may increase methylprednisolone levels. Dose reduction of methylprednisolone may be indicated. ■ May interact with **anticoagulants, nondepolarizing muscle relaxants, or theophyllines;** may inhibit or potentiate action; monitor carefully. ■ Monitor patients receiving **antidiabetic agents** carefully; dose adjustments may be required. ■ May antagonize effects of **isoniazid and salicylates;** dose adjustments may be required. ■ Administration of **live virus or live-attenuated vaccines** is contraindicated in patients receiving immunosuppressive doses of corticosteroids. Inactivated vaccines may be administered, but the response to such vaccines cannot be predicted. ■ Concomitant use with **NSAIDs** may increase the risk of adverse GI effects. ■ Concomitant use with **anticholinesterase agents** (e.g., neostigmine) may produce severe weakness in patients with myasthenia gravis. If possible, anticholinesterase agents should be withdrawn at least 24 hours before initiating corticosteroid therapy. ■ Corticosteroids may **suppress reactions to skin tests.** ■ See Dose Adjustments.

SIDE EFFECTS

Do occur but are usually reversible: Cushing’s syndrome; electrolyte and calcium imbalance; euphoria; fluid retention; glycosuria; hepatitis; hyperglycemia; hypersensitivity reactions, including anaphylaxis; hypertension; impaired wound healing; increased appetite; increased intracranial pressure; leukocytosis; menstrual irregularities; ophthalmic disorders (glaucoma, increased intraocular pressure); peptic ulcer perforation and hemorrhage; protein catabolism; spontaneous fractures; transitory burning or tingling, sweating, headache, or weakness; thromboembolism; and many others.

ANTIDOTE

Notify the physician of any side effect. Will probably treat the side effect if necessary. Treat acute overdose with supportive and symptomatic therapy. For chronic overdosage in the face of severe disease requiring continuous steroid therapy, the dosage of the corticosteroid may be reduced only temporarily, or alternate day treatment may be introduced. Discontinue methylprednisolone if toxic hepatitis occurs. Do not rechallenge patient. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

METOCLOPRAMIDE HYDROCHLORIDE BBW

(**meh**-toe-kloh-**PRAH**-myd hy-droh-**KLOR**-eyed)
Reglan
GI stimulant
Antiemetic
pH 4.5 to 6.5

USUAL DOSE

Small bowel intubation and/or radiologic examination of the small bowel:

10 mg (2 mL) as a single dose.

Antiemetic:

High-dose regimen for highly emetogenic chemotherapy is rarely used; 5-HT_3 receptor antagonists (e.g., ondansetron) preferred. 2 mg/kg of body weight 30 minutes before giving emetogenic cancer chemotherapy (e.g., cisplatin, dacarbazine). Repeat every 2 hours for 2 doses, then every 3 hours for 3 doses; see Dose Adjustments. For less emetogenic regimens, 1 mg/kg/dose may be adequate.

Diabetic gastroparesis:

10 mg immediately before each meal and at bedtime. Use IV for up to 10 days if symptoms are severe. Continue treatment PO for 2 to 8 weeks.

Prevention of postoperative nausea and vomiting:

10 mg, usually given IM toward the end of surgery. Up to 20 mg may be used.

PEDIATRIC DOSE

Small bowel intubation and/or radiologic examination of the small bowel:

6 to 14 years: 2.5 to 5 mg. ***Under 6 years:*** 0.1 mg/kg of body weight.

Gastroesophageal reflux or GI dysmotility (unlabeled):

0.1 to 0.2 mg/kg/dose. May be given every 6 hours if required. Maximum dose 0.8 mg/kg/24 hr (0.2 mg/kg/dose every 6 hours).

Antiemetic (unlabeled):

Rarely used. 5-HT_3 receptor antagonists preferred. A high-dose regimen for highly emetogenic chemotherapy of 1 to 2 mg/kg/dose every 2 to 6 hours has been administered but is rarely used. Premedicate with diphenhydramine to reduce extrapyramidal symptoms.

DOSE ADJUSTMENTS

Antiemetic dose may be reduced to 1 mg/kg if initial doses suppress vomiting. Initial doses may be reduced to 1 mg/kg for less emetogenic regimens. ■ Reduce initial dose by half in any patient with a CrCl less than 40 mL/min. Adjust subsequent doses as indicated. ■ Caution and lower-end dosing suggested in elderly patients. Consider potential for decreased organ function and concomitant disease or drug therapy. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted if dose does not exceed 10 mg. For doses exceeding 10 mg dilute in at least 50 mL of D5W, NS, D5/½NS, R, or LR, and give as an infusion.

Storage:

Light sensitive; store in carton before use. Diluted solutions stable for 24 hours in normal light, 48 hours if protected from light. Do not freeze unless diluted in NS. Discard if color or particulate matter is observed.

COMPATIBILITY

Manufacturer lists as **incompatible** with chloramphenicol and sodium bicarbonate. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Too-rapid IV injection will cause intense anxiety, restlessness, and then drowsiness.

IV injection:

10 mg or fraction thereof over 2 minutes. Reduce rate of injection in pediatric patients.

Infusion:

Administer over a minimum of 15 minutes.

ACTIONS

A dopamine antagonist. Antiemetic properties appear to be the result of antagonism of central and peripheral dopamine receptors. Blocks the stimulation of medullary chemoreceptor trigger zones by dopamine. Inhibits nausea and vomiting. Increases tone and amplitude of gastric contractions, relaxes the lower pyloric sphincter and duodenal bulb, and increases peristalsis of the duodenum and jejunum, resulting in accelerated gastric emptying. Does not stimulate gastric, biliary, or pancreatic secretions. Acts even if vagal innervation not present. Action negated by anticholinergic drugs. Distributes extensively into tissues. Onset of action occurs in 1 to 3 minutes and lasts 1 to 2 hours. Average half-life is 5 to 6 hours. Excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Facilitate small bowel intubation. ■ Stimulate gastric and intestinal emptying of barium to permit radiologic examination of the stomach and small intestine. ■ Prevention of nausea and vomiting associated with emetogenic cancer chemotherapy. ■ Prophylaxis of postoperative nausea and vomiting when nasogastric suction is not indicated. ■ Diabetic gastroparesis.

CONTRAINDICATIONS

Situations in which gastric motility is contraindicated (i.e., gastric hemorrhage, obstruction, or perforation); known hypersensitivity to metoclopramide; patients with epilepsy or patients taking drugs that may also cause extrapyramidal reactions; pheochromocytoma.

PRECAUTIONS

May produce sedation, extrapyramidal symptoms, or Parkinson-like symptoms, similar to those seen with phenothiazines. Use caution in patients with pre-existing disease. ■ Acute dystonic reactions (a type of extrapyramidal symptom [EPS]) are usually seen during the first 24 to 48 hours of treatment and are more common in pediatric patients, in adults under 30 years of age, and at higher doses used for prophylaxis of N/V due to chemotherapy. ■ Tardive dyskinesia may develop and is usually related to duration of treatment and total cumulative dose. Avoid use for longer than 12 weeks unless benefit outweighs risk of tardive dyskinesia. ■ Neuroleptic malignant syndrome (NMS) has been reported rarely. Potentially fatal. Discontinue metoclopramide immediately; see Monitor. ■ Produces a transient increase in plasma aldosterone; patients with cirrhosis or CHF may develop fluid retention and volume overload. If S/S occur, discontinue metoclopramide. ■ Use with caution in patients with hypertension. May cause release of catecholamines, exacerbating the condition. ■ A prolactin-elevating compound; may be carcinogenic. Risk with a single dose almost nonexistent. ■ May cause serious depression and suicidal tendencies; use extreme caution in any patient with a history of depression. ■ Patients with NADH-cytochrome b_5 reductase deficiency are at increased risk for developing methemoglobinemia and/or sulfhemoglobinemia. In patients with G6PD deficiency who develop methemoglobinemia, methylene blue treatment is not recommended. Can cause hemolytic anemia. ■ See Maternal/Child.

Monitor:

Monitor vital signs. ■ Pretreatment with diphenhydramine may reduce incidence of extrapyramidal symptoms with larger doses (e.g., antiemetic). ■ Monitor for S/S of NMS (e.g., hyperthermia, muscle rigidity, altered consciousness, and evidence of autonomic instability [irregular pulse or BP, tachycardia, diaphoresis, and arrhythmias]). ■ Discontinue therapy in patients who develop S/S of tardive dyskinesia (syndrome of potentially irreversible involuntary movements of the tongue, face, mouth, jaw, trunk, or extremities). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Use caution performing any task that requires alertness, coordination, or physical dexterity; may produce dizziness and drowsiness. ■ If any involuntary movement of eyes, face, or limbs occurs, notify physician promptly. ■ Avoid alcohol or other CNS depressants (e.g., barbiturates, benzodiazepines [e.g., diazepam]).

Maternal/Child:

Category B: use caution in pregnancy and breast-feeding. ■ May increase milk production (elevates prolactin). ■ Pharmacokinetics highly variable in children and neonates. ■ Safety and effectiveness for use in pediatric patients not established except when administered to facilitate small bowel intubation. ■ Dystonic reactions are more common in pediatric patients. ■ Prolonged clearance in neonates may produce excessive serum concentrations. ■ May cause methemoglobinemia in premature and full-term neonates at doses exceeding 0.5 mg/kg/24 hr. ■ See Precautions and Side Effects.

Elderly:

May be more sensitive to therapeutic or adverse effects. ■ Long-term use increases risk of extrapyramidal effects (e.g., parkinsonism, tardive dyskinesia). ■ See Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

Antagonized by **anticholinergic drugs** (e.g., atropine) **and narcotic analgesics** (e.g., morphine). ■ May potentiate **alcohol and cyclosporine.** ■ Drugs ingested orally may be absorbed more slowly or more rapidly depending on the absorption site (e.g., inhibits **cimetidine, digoxin**). ■ Potentiates **MAO inhibitors**; use extreme caution or do not use. ■ **Insulin** reactions may result from gastric stasis, making diabetic control difficult. Dose or timing of insulin may need adjustment. ■ Extrapyramidal effects may be potentiated with concomitant use of **phenothiazines, butyrophenones, and thioxanthines** (antipsychotic drugs). ■ Used concurrently, metoclopramide and **levodopa** have opposite effects on dopamine receptors; metoclopramide is inhibited, and levodopa is potentiated.

SIDE EFFECTS

Usually mild, transient, and reversible after metoclopramide is discontinued. Hypersensitivity reactions can occur. Acute CHF, anxiety, arrhythmias, bowel disturbances, confusion, convulsions, depression (severe, may have suicidal tendencies), dizziness, drowsiness, extrapyramidal reactions, fatigue, fluid retention, hallucinations, headache, hypertension, hypotension, insomnia, methemoglobinemia in neonates, nausea, NMS (hyperthermia, muscle rigidity, altered consciousness, and evidence of autonomic instability [irregular pulse or BP, tachycardia, diaphoresis, and arrhythmias]), restlessness, sulfhemoglobinemia in adults, tardive dyskinesia. Numerous other side effects may occur.

Overdose:

Disorientation, drowsiness, and extrapyramidal reactions.

ANTIDOTE

Notify physician of all side effects. Most will respond to a reduced dose or discontinuation of metoclopramide. Treat overdose or extrapyramidal reactions with diphenhydramine or benztropine. Symptoms should disappear within 24 hours. To manage NMS, immediately discontinue metoclopramide. Intensive symptomatic treatment and monitoring are required. Discontinue therapy in patients who develop S/S of tardive dyskinesia; symptoms may resolve. Treat methemoglobinemia with IV methylene blue. Hemodialysis is not likely to be useful in an overdose. Resuscitate as necessary.

METOPROLOL TARTRATE BBW

(me-toe-**PROH**-lohl **TAHR**-trayt)
Lopressor
Beta-adrenergic blocking agent
Antiarrhythmic (post MI)
pH 7.5

USUAL DOSE

Pretreatment:

See Monitor.

Treatment of myocardial infarction (MI):

5 mg as an IV bolus dose. Initiate as soon as the patient’s hemodynamic condition has stabilized. Repeat at 2-minute intervals for 2 more doses; a total dose of 15 mg (AHA recommends 5 mg at 5-minute intervals to a total dose of 15 mg). If IV doses are well tolerated, give 50 mg PO every 6 hours for 48 hours beginning 15 minutes after the last bolus. Follow with an oral maintenance dose of 100 mg twice daily. In patients who do not tolerate the full IV dose start 25 to 50 mg PO within 15 minutes of the last IV dose. Dosage based on degree of intolerance. May have to discontinue metoprolol.

Treatment of atrial fibrillation (unlabeled):

2.5 to 5 mg as an IV injection over 2 to 5 minutes as necessary to control rate up to a total dose of 15 mg in a 10- to 15-minute period if indicated.

Treatment of ventricular rate control/hypertension (unlabeled):

1.25 to 5 mg every 6 to 12 hours. Begin with a lower initial dose and titrate to response. Up to 15 mg every 3 to 6 hours has been used.

DOSE ADJUSTMENTS

See Drug/Lab Interactions. ■ Not required in impaired renal function. ■ In patients with impaired hepatic function, start at a low dose and titrate upward slowly.

DILUTION

May be given undiluted.

Storage:

Store at CRT. Protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over 1 minute. Monitor ECG, HR, and BP and discontinue metoprolol if adverse symptoms occur (bradycardia less than 45 beats/min, heart block greater than first degree, systolic BP less than 100 mm Hg, or moderate to severe cardiac failure).

ACTIONS

Metoprolol is a cardioselective (B_1) adrenergic receptor blocker. Its mechanism of action in patients with suspected or definite MI is not known, but its use has been shown to reduce the 3-month mortality rate in this patient population. It reduces the incidence of recurrent MI and reduces the size of the infarct and the incidence of fatal arrhythmias. Reduces HR, systolic BP, and cardiac output. Well distributed throughout the body, it acts within 1 to 2 minutes and lasts about 3 to 4 hours. Maximum beta blockade is achieved in approximately 20 minutes. Metabolized in the liver by the cytochrome P_{450} enzyme system, primarily CYP2D6. Excreted as metabolites in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

To reduce cardiac mortality in hemodynamically stable individuals with suspected or definite MI (used in conjunction with oral metoprolol maintenance therapy). ■ Treatment of hypertension, angina pectoris, and CHF in oral dosage form.

Unlabeled uses:

Treatment of atrial fibrillation and unstable angina. ■ Has been used in the perioperative period to reduce cardiac morbidity and mortality in patients at risk. ■ Treatment of ventricular rate control and hypertension in patients who cannot take PO medications.

CONTRAINDICATIONS

HR below 45 beats/min, second- or third-degree heart block, significant first-degree heart block (PR interval equal to or greater than 0.24 second), systolic BP below 100 mm Hg, or moderate to severe cardiac failure. ■ Hypersensitivity to metoprolol or to any of the excipients. Use caution in patients with hypersensitivity to other beta-blockers. Cross-sensitivity between beta-blockers can occur. ■ Severe peripheral arterial circulatory disorders or sick sinus syndrome in patients with angina or hypertension.

PRECAUTIONS

Use caution in CHF. Beta blockade may depress myocardial contractility and precipitate or exacerbate heart failure and cardiogenic shock. ■ Use caution in presence of heart failure controlled by digoxin. Both drugs slow AV conduction. Bradycardia, sinus pause, heart block, and cardiac arrest have occurred. Patients with first-degree AV block, sinus node dysfunction, or conduction disorders may be at increased risk; see Antidote. ■ May produce significant first- (PR interval equal to or greater than 0.26 second), second-, or third-degree heart block. Acute MI can also cause heart block. ■ Metoprolol decreases sinus heart rate. MI may also produce significant lowering of HR; see Antidote. ■ Routine withdrawal of chronically administered beta-blockers before major surgery is not necessary; however, the risks of general anesthesia and surgical procedures may be increased by the impaired ability of the heart to respond to reflex adrenergic stimuli. ■ Use caution in patients with a history of severe anaphylactic reactions to a variety of allergens; they may be more reactive to repeated challenge (either accidental, diagnostic, or therapeutic) and may be unresponsive to the usual doses of epinephrine used to treat hypersensitivity reactions; see Drug/Lab Interactions. ■ May mask tachycardia occurring with hypoglycemia in diabetes and tachycardia of hyperthyroidism. ■ In general, patients with bronchospastic disease should not receive beta-blockers, including metoprolol. Because of its relative beta selectivity, metoprolol may be used with extreme caution in these patients. Monitor pulmonary function closely; see Antidote. ■ Use with caution in patients with impaired hepatic function; see Dose Adjustments. ■ May cause arrhythmia, angina, MI, or death if stopped abruptly (more of an issue with chronic oral therapy); see prescribing information. ■ May cause severe bradycardia in patients with Wolff-Parkinson-White syndrome. ■ Contraindicated in patients known to have or suspected of having a pheochromocytoma. If metoprolol is required, it should be given in combination with an alpha-blocker (e.g., phenoxybenzamine [Dibenzyline]) and only after the alpha-blocker has been initiated. ■ See Drug/Lab Interactions.

Monitor:

Continuous ECG, HR, BP monitoring mandatory with use of IV metoprolol. ■ Hemodynamic status must be closely monitored. If heart failure or hypotension occurs or persists despite appropriate treatment, metoprolol should be discontinued. Assess extent of myocardial damage. Invasive monitoring of central venous, pulmonary capillary wedge, and arterial pressure may be required. ■ See Drug/Lab Interactions and Antidote.

Patient Education:

Report any breathing difficulty promptly.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding and in pediatric patients not established. ■ If a pregnancy occurs, women should inform physician.

Elderly:

Age-related differences in safety and effectiveness not identified; however, greater sensitivity of some elderly cannot be ruled out. Dose with caution. ■ May exacerbate mental impairment.

DRUG/LAB INTERACTIONS

Concurrent use with **calcium channel blockers** (e.g., diltiazem, verapamil) may potentiate both drugs and result in severe depression of myocardium and AV conduction and severe hypotension. ■ Concurrent use with **antihypertensive agents,** including **alpha-adrenergic blockers** (e.g., clonidine, methyldopa), may result in excessive hypotension. Dose adjustment may be required. ■ Concurrent administration with **hydralazine** may decrease metabolism and increase concentrations of metoprolol. ■ **Potent inhibitors of the CYP2D6 enzyme** may increase plasma concentrations of metoprolol and decrease its cardioselectivity. These inhibitors include **antidepressants** (e.g., clomipramine, desipramine, fluoxetine, fluvoxamine, paroxetine, sertraline, bupropion), **antipsychotics** (e.g., chlorpromazine, fluphenazine, haloperidol, thioridazine), **antiarrhythmics** (e.g., quinidine, propafenone), **antiretrovirals** (e.g., ritonavir), **antihistamines** (e.g., diphenhydramine), **antimalarials** (e.g., hydroxychloroquine, quinidine), **allylamine antifungals** (e.g., terbinafine). ■ Concurrent use within 14 days of **MAO inhibitors** may cause severe hypertension. ■ Use with **sympathomimetic agents** (e.g., epinephrine, norepinephrine, phenylephrine) **or xanthines** (e.g., aminophylline) may negate therapeutic effects of both drugs. ■ Effects of beta-adrenergic blocking agents may be decreased by **anti-inflammatory drugs** (e.g., NSAIDs), **barbiturates, rifampin, salicylates, and others.** ■ **Inhalation anesthetics, phenytoin**, **and quinolone antibiotics** may increase myocardial depressant effects and hypotension. ■ Beta-adrenergic blocking agents may be continued during the perioperative period in most patients; however, use caution with **selected anesthetic agents** that may depress the myocardium. ■ Potentiates effects of **oral antidiabetics, catecholamine-depleting drugs** (e.g., reserpine), insulin, lidocaine, and skeletal muscle relaxants; monitor carefully. Dose adjustment may be required. ■ Concurrent use with **clonidine** may precipitate acute hypertension if one or both agents are stopped abruptly. Withdraw metoprolol first. ■ Effects decreased when hypothyroid patient is **converted to a euthyroid state;** adjust dose as indicated. ■ Use caution; both **digoxin** and beta-blockers slow AV conduction. May increase risk of bradycardia. ■ Patients taking beta-blockers who are exposed to a potential allergen may be unresponsive to the usual dose of **epinephrine** used to treat a hypersensitivity reaction. ■ May enhance the vasoconstrictive action of **ergot alkaloids.** ■ In general, withhold administration of a beta-blocker before **dipyridamole** testing; monitor HR carefully following dipyridamole injection.

SIDE EFFECTS

Abdominal pain, bradyarrhythmias, bronchospasm, cardiac failure, claudication, confusion, dizziness, dyspnea, elevated liver function tests, first-degree heart block, hallucinations, headache, hepatitis, hypotension, jaundice, nausea, nightmares, pruritus, rash, reduced libido, respiratory distress, second- or third-degree heart block, sleep disturbances, syncopal attacks, tiredness, unstable diabetes, vertigo, visual disturbances.

ANTIDOTE

For any side effect, discontinue drug and notify physician immediately. Patients with MI may be more hemodynamically unstable; treat with caution. Use atropine (0.25 to 0.5 mg) for bradycardia or heart block; use isoproterenol with caution if atropine is not effective. Glucagon 5 to 10 mg IV may be effective if atropine and isoproterenol are not (investigational use). Transvenous cardiac pacing may be needed. Treat hypotension with IV fluids if indicated or vasopressors (dopamine or norepinephrine [Levarterenol]); treat cause of hypotension (e.g., bradycardia). Use all vasopressors with extreme caution; severe hypotension can result. Use digoxin and diuretics at first sign of cardiac failure; dobutamine, isoproterenol, or glucagon may be required. Use aminophylline or isoproterenol (with extreme care) for bronchospasm, and glucagon or IV glucose for hypoglycemia. Treat other side effects symptomatically; resuscitate as necessary.

METRONIDAZOLE HYDROCHLORIDE BBW

(meh-troh-**NYE**-dah-zohl hy-droh-**KLOR**-eyed)
Metro IV
Antibacterial
Antiprotozoal
Amebicide
pH 4.5 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

May transfer to oral therapy when condition warrants (usual PO dose is 7.5 mg/kg every 6 hours). Dosage, rate of administration, and duration of treatment are to be individualized and depend on the indication for use; the patient’s age, weight, clinical condition, and concomitant treatment; and on the patient’s clinical and laboratory response to the treatment.

Anaerobic infections:

500 mg every 6 to 8 hours for 7 to 10 days or longer if indicated. Infections involving bone and joint, lower respiratory tract, and endocardium may require longer treatment. Do not exceed 4 Gm in 24 hours.

Surgical prophylaxis to prevent postoperative infection in contaminated or potentially contaminated colorectal surgery:

500 mg IV within 60 minutes before surgical incision in combination with other antibiotics.

PEDIATRIC DOSE

Safety for use in infants and other pediatric patients not established, but is used for anaerobic infections; see Maternal/Child.

Anaerobic infections:

Pediatric patients more than 7 days of age:

7.5 mg/kg every 6 hours with a maximum dose of 4 Gm/24 hr.
Another source recommends age- and weight-specific doses as follows:

Less than 7 days of age weighing less than 1.2 kg:

7.5 mg/kg every 48 hours.

Less than 7 days of age weighing 1.2 to 2 kg:

7.5 mg/kg every 24 hours.

Less than 7 days of age weighing 2 or more kg:

7.5 mg/kg every 12 hours.

7 days of age or older weighing less than 1.2 kg:

7.5 mg/kg every 24 hours.

7 days of age or older weighing 1.2 to 2 kg:

7.5 mg/kg every 12 hours.

7 days of age or older weighing 2 or more kg:

15 mg/kg every 12 hours.

DOSE ADJUSTMENTS

Reduce dose by 50% in patients with severe (Child-Pugh Class C) hepatic impairment. ■ Reduce the dose as necessary in patients with severe hepatic encephalopathy who experience an exacerbation of CNS adverse effects. ■ Increase intervals in neonates; see Pediatric Dose. ■ No dose adjustment is indicated in mild to moderate impaired renal function. ■ Dose adjustment not indicated in anuric patients; accumulated metabolites readily removed by dialysis. 40% to 65% of a metronidazole dose can be removed by dialysis depending on length of dialysis session and type of dialyzer membrane used. If metronidazole administration cannot be separated from dialysis session, consider supplemental dose following dialysis. ■ Continuous NG suction may remove sufficient metronidazole in gastric aspirate to reduce serum levels. No dose adjustment is recommended.

DILUTION

All solutions are prediluted and ready to use (5 mg/mL). Do not use plastic containers in series connections. Risk of air embolism is present.

Storage:

Store at room temperature (25° C [77° F]). Do not refrigerate. Protect from light. Do not remove premixed product from overwrap until ready for use. After removing overwrap, check for minute leaks by squeezing bag firmly. Discard solution if leaks are found.

COMPATIBILITY

Manufacturer recommends, "Administer separately, discontinue the primary IV during administration, and do not introduce additives into the solution." Do not use equipment containing aluminum (e.g., needles, cannulae) that would come in contact with the drug solution as precipitates may form. Manufacturer lists as **incompatible** (includes but is not limited to) aztreonam, cefoxitin, and penicillin G.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Must be given as a slow intermittent or continuous IV infusion, each single dose evenly distributed over 1 hour. Discontinue primary IV during administration.

Surgical prophylaxis:

Administer each single dose over 30 to 60 minutes.

ACTIONS

A bactericidal agent with cytotoxic effects, active against specific obligate anaerobic bacteria and protozoa. Does not possess any clinically relevant activity against facultative anaerobes or obligate aerobes. Metronidazole enters the organism by passive diffusion and is reduced. The reduced form and free radicals that are produced during the reduction reaction interact with DNA, leading to inhibition of DNA synthesis and to DNA degradation and death of bacteria. The precise mechanism of action is unclear. Metronidazole is widely distributed. Plasma concentrations are directly proportional to dose given. Metabolized in the liver. Half-life is 8 hours. Crosses placental and blood-brain barriers. Excreted primarily in urine, some in feces. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections caused by susceptible strains of anaerobic bacteria, including serious intra-abdominal, skin and skin structure, gynecologic, bone and joint, CNS, and lower respiratory tract infections, bacterial septicemia, and endocarditis. Is effective in *Bacteroides fragilis* infections resistant to clindamycin, chloramphenicol, and penicillin. ■ Perioperative prophylaxis to reduce infection rates in contaminated or potentially contaminated colorectal surgery. ■ Given orally for amebiasis, giardiasis, *Helicobacter pylori* eradication, and other indications.

Unlabeled uses:

Clostridium difficile–associated diarrhea (CDAD), Crohn's disease.

CONTRAINDICATIONS

Hypersensitivity to metronidazole or other nitroimidazole derivatives; use of disulfiram within the last 2 weeks; use of alcohol or products containing propylene glycol during and for at least 3 days after therapy with metronidazole.

PRECAUTIONS

A mixed (anaerobic/aerobic) infection will require use of additional antibiotics targeted for treatment of the aerobic infection. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to metronidazole. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, metronidazole should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of the drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Symptoms of candidiasis may be exacerbated and require treatment. ■ Severe neurologic disturbances, including encephalopathy, cerebellar symptoms, convulsive seizures, peripheral neuropathy, optic neuropathy, and aseptic meningitis, have been reported in patients treated with metronidazole. CNS symptoms and lesions are generally reversible within days to weeks after metronidazole is discontinued. ■ Encephalopathy may manifest as confusion or a decreased level of consciousness and is associated with widespread lesions seen on MRI of the brain. Cerebellar toxicity may manifest as ataxia, dizziness, dysarthria, nystagmus, and saccadic pursuit. Accompanied by T2 flair lesions within the dentate nuclei seen on MRI. ■ Cerebellar toxicity may occur concurrently with encephalopathy, peripheral neuropathy, or seizures. ■ Peripheral neuropathy (usually symmetric and mainly sensory with S/S of numbness or paresthesia of extremities) has been reported. Symptoms may be prolonged after metronidazole is discontinued. ■ Aseptic meningitis may occur within hours of dose administration, and symptoms generally resolve after metronidazole is discontinued. ■ Use caution in patients predisposed to edema and/or taking corticosteroids or receiving a controlled sodium diet, or in patients with impaired cardiac function (contains 27 to 28 mEq sodium/Gm). ■ Use caution in patients with CNS disease or hepatic or renal impairment. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with metronidazole. ■ Carcinogenic in rodents; avoid unnecessary use and restrict use to approved indications. ■ Use with caution in patients with evidence of or a history of blood dyscrasias. Agranulocytosis, leukopenia, and neutropenia have occurred. ■ Severe hepatotoxicity/acute hepatic failure (including fatal outcome) with very rapid onset after treatment initiation in patients with Cockayne syndrome have been reported with products containing metronidazole for systemic use. Use in this population only if no alternative treatment is available. ■ Exacerbation of CNS adverse effects may occur in patients with severe hepatic encephalopathy; see Dose Adjustments.

Monitor:

Monitor CBC before, during, and after prolonged or repeated courses of therapy and in patients with symptoms of blood dyscrasias (e.g., agranulocytosis, leukopenia, and neutropenia). ■ Obtain liver function tests before the start of therapy, within the first 2 to 3 days after the initiation of therapy, frequently during therapy, and after the end of treatment in patients with Cockayne syndrome. ■ Monitor for S/S of toxicity in patients with hepatic or renal impairment and in the elderly. ■ Monitor for adverse events when metronidazole is administered to those with severe renal impairment or end-stage renal disease who are not undergoing hemodialysis. ■ Monitor for S/S of toxicity due to the potential accumulation of metronidazole metabolites in those receiving peritoneal dialysis. ■ Monitor for neurologic S/S (e.g., ataxia, confusion, dizziness, dysarthrias, numbness, paresthesia, and seizures); see Antidote. ■ Monitor for S/S of bleeding. ■ Transfer to oral dosing as soon as practical. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol and alcohol-containing preparations during and for at least 3 days after completion of therapy; toxic reactions will occur. ■ Review medications with health care provider; see Drug/Lab Interactions. ■ Promptly report any neurologic side effects (e.g., seizures, numbness, or paresthesia of an extremity). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Patients with Cockayne syndrome should stop taking metronidazole immediately and promptly report any S/S of potential liver injury (e.g., abdominal pain, change in stool color, jaundice, or nausea).

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Discontinue breast-feeding during metronidazole therapy and for 24 hours after therapy ends. ■ Safety for use in pediatric patients and neonates not established. The elimination half-life, measured during the first 3 days of life, was inversely related to gestational age. Half-life markedly extended in newborns; adjust intervals; see Pediatric Dose.

Elderly:

Pharmacokinetics altered in the elderly; monitor for metronidazole-associated adverse events and adjust dose accordingly. Dose selection should be cautious, reflecting the greater frequency of decreased hepatic, renal, or cardiac function and of concomitant disease or other drug therapy.

DRUG/LAB INTERACTIONS

Avoid **alcohol and alcohol-containing preparations** for at least 3 days after taking any dose of metronidazole; a disulfiram-like reaction (abdominal cramps, flushing, headaches, nausea, tachycardia, and vomiting) may occur. ■ Avoid administration of metronidazole to patients who have taken **disulfiram** within the last 2 weeks. Psychotic reactions and confusion have been reported. ■ Concurrent use with **drugs that induce microsomal enzyme activity** (e.g., phenobarbital, phenytoin) may increase metabolism of metronidazole and decrease plasma levels, thereby decreasing efficacy. ■ Administration with **drugs that inhibit microsomal liver enzyme activity** may decrease metronidazole metabolism, increasing metronidazole plasma levels and the risk of toxicity. ■ Concurrent use with **CYP3A4 substrates** (e.g., amiodarone, carbamazepine, cyclosporine, phenytoin, quinidine, tacrolimus) may increase substrate plasma levels. Monitoring of plasma concentrations of CYP3A4 substrates may be necessary. ■ Metronidazole decreases the clearance of **5-fluorouracil** and may therefore cause 5-fluorouracil toxicity. ■ Metronidazole may potentiate the effects of **vecuronium**. ■ Potentiates the anticoagulant effects of **warfarin**. Monitor PT/INR periodically and adjust anticoagulant dose accordingly. ■ May increase **lithium** levels and cause toxicity. Frequent monitoring of serum lithium and serum creatinine levels is necessary. ■ May increase plasma concentrations of **busulfan**, increasing the risk of serious busulfan toxicity such as sinusoidal obstruction syndrome, gastrointestinal mucositis, and hepatic veno-occlusive disease. Avoid concomitant use if possible. If concomitant administration is medically necessary, monitor busulfan plasma concentration and adjust busulfan dose accordingly. ■ May interfere with **selected chemistry studies** (e.g., AST, ALT, LDH, triglycerides, glucose hexokinase).

SIDE EFFECTS

The most serious side effects include aseptic meningitis, seizures, encephalopathy, and optic and peripheral neuropathy. Abdominal cramping, agranulocytosis, arthralgia, asthenia, ataxia, chest pain, chills, chromaturia, CDAD, confusion, darkened deep red urine, decreased appetite, decreased libido, depression, diarrhea, dizziness, drug reaction with eosinophilia and systemic symptoms (DRESS), dysarthria, dysgeusia, dyspnea, dysuria, eosinophilia, erythema, facial edema, headache, increased hepatic enzyme, hepatotoxicity/liver failure in patients with Cockayne syndrome, hyperhidrosis, hypersensitivity reactions (including anaphylaxis), hypoesthesia, injection site reaction, insomnia, jaundice, leukopenia, malaise, myalgia, muscle spasms, nausea, neutropenia (reversible), numbness, nystagmus, painful coitus, palpitation, pancreatitis, paresthesia, peripheral edema, proctitis, pruritus, psychosis, rash, saccadic eye movement, somnolence, Stevens-Johnson syndrome, syncope, tachycardia, thrombocytopenia (reversible), toxic epidermal necrolysis, urticaria, vaginal candidiasis, vertigo, and vomiting have occurred.

Overdose:

Nausea, neurotoxic effects (including ataxia, confusion, disorientation, seizures, and peripheral neuropathy), and vomiting.

ANTIDOTE

Notify physician of all side effects. Treatment will be symptomatic and supportive. Evaluate risk versus benefit of continuing therapy in patients who develop abnormal neurologic S/S (e.g., encephalopathy, seizures, or signs of peripheral neuropathy). Discontinue metronidazole in patients with Cockayne syndrome who develop elevated liver function tests. Monitor liver function tests until the baseline values are reached. Removed by hemodialysis. Treat anaphylaxis and resuscitate as necessary.

MICAFUNGIN SODIUM

(my-kah-**FUN**-gin **SO**-dee-um)
Mycamine

Antifungal (echinocandin)
pH 5 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Treatment of candidemia, acute disseminated candidiasis, *Candida* peritonitis and abscesses:

100 mg/day as an infusion. Mean duration of treatment during clinical studies was 15 days (range 10 to 47 days).

Treatment of esophageal candidiasis:

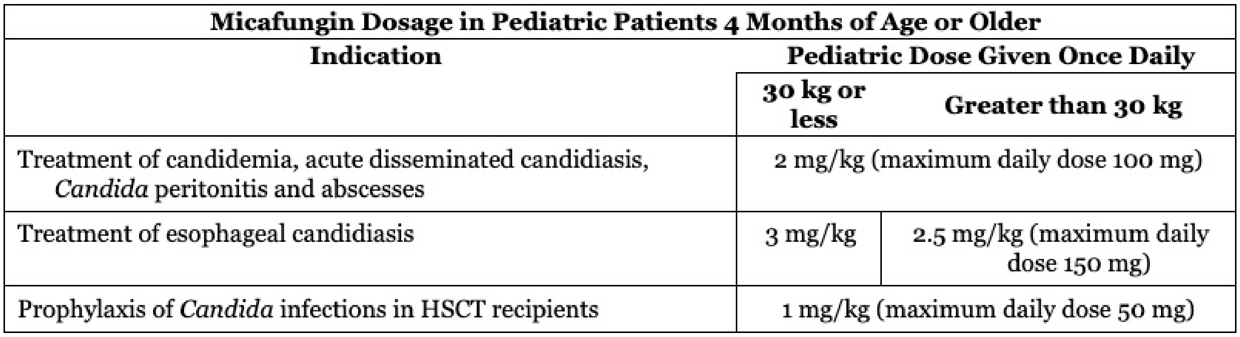
150 mg/day as an infusion. Mean duration of treatment during clinical studies was 15 days (range 10 to 30 days).

Prophylaxis of *Candida* infections in hematopoietic stem cell transplant (HSCT) recipients:

50 mg/day as an infusion. Mean duration of treatment in patients who responded successfully during clinical studies was 19 days (range 6 to 51 days).

PEDIATRIC DOSE

Recommended doses for pediatric patients based on indication and weight are outlined in the following chart.



Micafungin Dosage in Pediatric Patients 4 Months of Age or Older

Indication	**Pediatric Dose Given Once Daily**	
	30 kg or less	**Greater than 30 kg**
Treatment of candidemia, acute disseminated candidiasis, *Candida* peritonitis and abscesses	2 mg/kg (maximum daily dose 100 mg)	
Treatment of esophageal candidiasis	3 mg/kg	2.5 mg/kg (maximum daily dose 150 mg)
Prophylaxis of *Candida* infections in HSCT recipients	1 mg/kg (maximum daily dose 50 mg)	

Dosage for pediatric patients under 4 months of age:

Treatment of candidemia, acute disseminated candidiasis, Candida *peritonitis, and abscesses without meningoencephalitis and/ or ocular dissemination:* The recommended dose is 4 mg/kg once daily; see Limitations of Use.

DOSE ADJUSTMENTS

No dose adjustment indicated based on gender or race, in the elderly, or in patients with severe renal dysfunction or mild to moderate or severe hepatic insufficiency. ■ Not dialyzable; a supplementary dose following hemodialysis should not be required. ■ See Drug/Lab Interactions.

DILUTION

Each 50- or 100-mg vial must be reconstituted with 5 mL of NS (without a bacteriostatic agent) or with D5W. Following reconstitution, the 50-mg vial has a final concentration of 10 mg/mL. The 100-mg vial has a final concentration of 20 mg/mL. The use of strict aseptic technique is required. Swirl vial(s) gently to dissolve. ***Do not shake.*** Do not use if precipitation or foreign matter is observed. Each single adult dose (50, 100, or 150 mg) must be further diluted in 100 mL NS or D5W for infusion. For pediatric patients, calculate the dose in milligrams and withdraw the required volume from the selected concentration (10 mg/mL or 20 mg/mL). Add the withdrawn volume to an infusion bag or syringe containing NS or D5W. Final concentration of diluted solution should be between 0.5 and 4 mg/mL. Concentrations greater than 1.5 mg/mL should be infused through a central line.

Filters:

No study data available; if filtering is necessary, contact manufacturer.

Storage:

Store unopened vials at CRT. Reconstituted solution in original vial or diluted solution is stable up to 24 hours at 25° C (77° F). Protect diluted solution from light. Discard partially used vials.

COMPATIBILITY

Manufacturer states, "Do not mix or co-infuse micafungin with other medications. Has been shown to precipitate when mixed directly with a number of other commonly used medications." Flush IV line with NS before and after infusion.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush IV line with NS before and after infusion.

A single dose as an infusion equally distributed over 1 hour. Rapid infusion may result in more frequent histamine-mediated reactions (e.g., facial swelling, pruritus, rash, vasodilation). To minimize the risk of infusion reactions in pediatric patients, concentrations of greater than 1.5 mg/mL should be administered via a central catheter. Injection site reactions have been reported and occur more often in patients receiving micafungin via peripheral intravenous administration.

ACTIONS

A semi-synthetic lipopeptide. An echinocandin antifungal agent. Acts by inhibiting the synthesis of 1,3-beta-D-glucan, an integral component of the fungal cell wall not present in mammalian cells. The AUC increases as doses are increased (e.g., from 50 to 150 mg or from 3 to 8 mg/kg). Highly protein bound primarily to albumin but does not competitively displace bilirubin binding to albumin. 85% of steady-state concentration achieved after three daily doses. Metabolized in the liver. A substrate and weak inhibitor of CYP3A, but CYP3A is not a major pathway for metabolism. Half-life ranges from approximately 11 to 21 hours in adults and from 5 to 22 hours in pediatric patients. Primarily excreted in feces, with some excretion in urine.

INDICATIONS AND USES

Indicated in adult and pediatric patients 4 months of age and older for treatment of candidemia, acute disseminated candidiasis, *Candida* peritonitis, and abscesses. ■ Treatment of candidemia, acute disseminated candidiasis, *Candida* peritonitis, and abscesses ***without*** meningoencephalitis and/or ocular dissemination in pediatric patients under 4 months of age; see Limitations of Use. ■ Treatment of esophageal candidiasis in adult and pediatric patients 4 months of age and older. ■ Prophylaxis of *Candida* infections in patients undergoing hematopoietic stem cell transplantation.

Limitations of Use:

Safety and effectiveness of micafungin have ***not*** been established for the treatment of candidemia ***with*** meningoencephalitis and/or ocular dissemination in pediatric patients under 4 months of age as a higher dose may be needed. ■ Has not been adequately studied in patients with endocarditis, osteomyelitis, and meningitis due to *Candida* infections. ■ Efficacy against infections caused by fungi other than Candida not established.

CONTRAINDICATIONS

Hypersensitivity to micafungin, any of its components, or other echinocandins (e.g., anidulafungin), caspofungin.

PRECAUTIONS

Do not give as an IV bolus; for IV infusion only. ■ Isolated anaphylactoid reactions (including shock) and anaphylaxis have been reported. ■ Abnormal liver function tests have been reported. Isolated cases of significant hepatic dysfunction, hepatitis, or worsening hepatic failure have occurred. Incidence may be increased in patients with serious underlying conditions who are receiving additional concomitant medications. Evaluate risk versus benefit of continued micafungin therapy. ■ Elevations in BUN and creatinine have been reported. Isolated cases of significant renal dysfunction or acute renal failure have occurred. ■ Intravascular hemolysis and hemoglobinuria have been reported. Isolated cases of significant hemolysis and hemolytic anemia have occurred. Evaluate risk versus benefit of continued micafungin therapy. ■ Reports of clinical failures resulting from development of drug resistance have been reported. ■ See Monitor and Antidote.

Monitor:

Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Baseline CBC with differential and platelet count, BUN, SCr, and liver function tests (e.g., ALT, AST) may be indicated. ■ Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, hives, hypotension, rash, pruritus, swelling of eyelids, lips, or face); discontinue infusion if a hypersensitivity reaction occurs. ■ Monitor for evidence of worsening hepatic function (e.g., increased ALT, AST, serum alkaline phosphatase). ■ Monitor for evidence of worsening renal function (e.g., increased BUN, SCr). ■ Monitor for S/S of hemolytic anemia, hemolysis, and hemoglobinuria as indicated (lysis of RBCs, liberation of hemoglobin, blood in the urine). ■ Hematologic, hepatic, and renal effects may require discontinuation of micafungin.

Patient Education:

Promptly report shortness of breath, dizziness or fainting, itching, rash, or swelling of extremities. ■ Report S/S of liver dysfunction (anorexia, fatigue, jaundice, nausea and vomiting, dark urine, or pale stools). ■ Report any S/S of hemoglobinuria (blood in the urine). ■ Report S/S of renal dysfunction (decrease in urine output). ■ Review list of current medications with physician. Drug interactions are possible; see Drug/Lab Interactions.

Maternal/Child:

Pregnancy category C: use during pregnancy only if benefits justify risk to fetus. Some abnormalities, including abortion, occurred in animal studies. ■ Use caution if required during breast-feeding. Secreted in milk of drug-treated rats; not known if micafungin is secreted in human milk. ■ Safety and effectiveness for use in pediatric patients under 4 months of age not established. ■ Safety and effectiveness ***have*** been established for use in pediatric patients under 4 months of age for the treatment of candidemia ***without*** meningoencephalitis and/or ocular dissemination. Safety and effectiveness have ***not*** been established for use in the treatment of candidemia ***with*** meningoencephalitis and/or ocular dissemination in pediatric patients under 4 months of age as a higher dose may be needed.

Elderly:

Differences in response compared to younger adults not identified; however, greater sensitivity in the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

The effects of **itraconazole, nifedipine, and sirolimus** are increased with concurrent administration of micafungin. Monitor for itraconazole, nifedipine, or sirolimus toxicity and reduce their dose as indicated. ■ Not expected to alter effects of drugs metabolized by the CYP3A system.

SIDE EFFECTS

Side effect profile similar in both adult and pediatric patients. The most common side effects include diarrhea, fever, headache, nausea, thrombocytopenia, and vomiting. The most serious side effects that may occur regardless of indication include acute intravascular hemolysis, decreased WBC, hemoglobinuria, hemolytic anemia, histamine-mediated reactions (e.g., facial swelling, pruritus, rash, vasodilation), hypersensitivity reactions (e.g., anaphylaxis and anaphylactoid reactions [including shock]), significant hepatic dysfunction (e.g., hepatitis, hepatocellular damage, hyperbilirubinemia, or worsening hepatic failure), significant renal dysfunction, and/or acute renal failure. Abdominal pain, anemia, chills, delirium, dizziness, increased liver function tests (e.g., alkaline phosphatase, ALT, AST, BUN, transaminases), injection site reactions (including inflammation, phlebitis, and thrombophlebitis), leukopenia, lymphopenia, neutropenia, and somnolence occurred in patients treated for esophageal candidiasis. In addition, constipation, decreased appetite, dysgeusia (altered sense of taste), dyspepsia, fatigue, febrile neutropenia, flushing, hiccups, hyperbilirubinemia, hypertension, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, increased drug levels, increased SCr, and mucosal inflammation occurred in patients undergoing prophylactic use during HSCT.

Patients with esophageal candidiasis:

Also reported rash and phlebitis.

Patients with candidemia and other *Candida* infections and prophylaxis of *Candida* infection in HSCT:

Both reported bacteremia, hypertension, hypokalemia, hypomagnesemia, hypotension, peripheral edema, tachycardia, and thrombocytopenia.

Patients with candidemia and other *Candida* infections:

Also reported aggravated anemia, atrial fibrillation, bradycardia, decubitus ulcer, hyperkalemia, hypernatremia, hypoglycemia, increased blood alkaline phosphatase, pneumonia, sepsis, septic shock, vascular disorders.

Prophylaxis of *Candida* infection in HSCT:

Also reported anorexia, anxiety, constipation, cough, dizziness, dyspepsia, dyspnea, epistaxis, erythema, fatigue, febrile neutropenia, fluid overload, fluid retention, flushing, hypocalcemia, mucosal inflammation, neutropenia, pruritus, rash, and rigors.

Post-Marketing:

Disseminated intravascular coagulation (DIC), Stevens-Johnson syndrome, and toxic epidermal necrolysis.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Hematologic, hepatic, and renal effects may require evaluation for the risk/benefit of continuing micafungin. If a hypersensitivity reaction occurs, discontinue micafungin and treat as indicated. Appropriate treatment may include oxygen, epinephrine, antihistamines, vasopressors, corticosteroids, IV fluids, and ventilation equipment. S/S indicative of hepatic, renal, or hematologic side effects may require evaluation of benefits versus risk of continuing micafungin therapy. Not removed by hemodialysis. Resuscitate as indicated.

MIDAZOLAM HYDROCHLORIDE BBW

(my-**DAYZ**-oh-lam hy-droh-**KLOR**-eyed)
Midazolam HCl PF, Versed
Benzodiazepine
Sedative-hypnotic
Anesthetic adjunct
Amnestic
pH 3

USUAL DOSE

Pretreatment:

Presedation history required; see Monitor. See Maternal/Child.

Dose requirements for each patient may vary and will depend on the type and amount of premedication used. Doses given below are general guidelines. Individualize dose and titrate slowly to effect. Allow at least 2 minutes between each small injection to evaluate the full effect before administering additional doses.

Sedation, Anxiolysis (Antianxiety), and/or Amnesia for Short Diagnostic, Endoscopic, and Therapeutic Procedures

The initial IV dose for sedation in adult patients may be as little as 1 mg but should not exceed 2.5 mg in a normal healthy adult. Lower doses are necessary in patients over 60 years of age, debilitated patients, or patients receiving concomitant narcotics or other CNS depressants; see Dose Adjustments.

The desired endpoint for conscious sedation can usually be achieved in 3 to 5 minutes. Time will depend on total dose and type or dose of narcotic premedication used concomitantly.

Healthy adults under 60 years of age:

1 to 2.5 mg immediately before the procedure.

Begin with 1 mg and titrate slowly up to slurred speech or 2.5 mg. Some patients respond adequately to 1 mg. If additional medication is needed, wait a full 2 minutes, then titrate additional dosage slowly in small increments. Wait a full 2 minutes between each increment. A total dose exceeding 5 mg is rarely necessary. Reduce dose by 30% in the presence of narcotic premedication or other CNS depressants. 25% of the sedating dose can be used for maintenance only when clearly indicated by clinical evaluation.

Patients over 60 years of age or debilitated or chronically ill patients:

1 to 1.5 mg. Begin with 1 mg and titrate slowly up to slurred speech or 1.5 mg. May respond adequately to 1 mg. If additional medication is needed, wait a full 2 minutes, then titrate additional dosage in small increments (no more than 1 mg). Wait a full 2 minutes between each increment. A total dose exceeding 3.5 mg is rarely necessary. Reduce dose by 50% in the presence of narcotic premedication or other CNS

depressants. 25% of the sedating dose can be used for maintenance only when clearly indicated by clinical evaluation. 0.2 mg/kg as an initial dose may be adequate.

Sedation for Anesthesia or Treatment in a Critical Care Setting for Intubated and Mechanically Ventilated Patients

Continuous infusion:

Begin with a ***loading dose*** of 0.01 to 0.05 mg/kg (0.5 to 4 mg for a typical adult) to rapidly initiate sedation, if needed. Infuse over several minutes. May be repeated at 10- to 15-minute intervals until adequate sedation achieved.

For maintenance of sedation:

An initial infusion rate of 0.02 to 0.1 mg/kg/hr (1 to 7 mg/hr) may be used. Upper-end doses may be required, but use the lowest recommended doses in patients with residual effects from anesthetic drugs or in those concurrently receiving other sedatives or opioids. Initial infusion rate may be titrated up or down by 25% to 50% to maintain desired level of sedation. Decrease by 10% to 25% every few hours to find the minimum effective infusion rate. The lowest rate that produces the desired level of sedation is recommended. Agitation, hypertension, or tachycardia in response to stimulation in adequately sedated patients may indicate need for an opioid analgesic. Reduced rate of midazolam infusion may be indicated with the addition of an opioid analgesic. Taper dose gradually if midazolam has been used for more than a few days. Abrupt discontinuation may result in withdrawal symptoms.

Refractory Status Epilepticus (Unlabeled)

The Neurocritical Care Society recommends 0.2 mg/kg as a loading dose. Follow with a continuous infusion of 0.05 to 2 mg/kg/hr. Titrate to cessation of electrographic seizures. See literature for further information.

PEDIATRIC DOSE

In all situations, dose is based on lean body weight in obese pediatric patients. See Precautions and Maternal/Child.

Sedation, Anxiolysis, Amnesia

Intubated pediatric patients in critical care settings:

Begin with a loading dose of 0.05 to 0.2 mg/kg. May be allowed to breathe on own through intubation tube but assisted ventilation recommended in pediatric patients receiving other CNS depressants. In hemodynamically compromised pediatric patients, titrate the loading dose in small increments and monitor for hypotension, respiratory rate, and oxygen saturation. May be followed by a continuous IV infusion at 0.06 to 0.12 mg/kg/hr (1 to 2 mcg/kg/min). Increase or decrease infusion in 25% increments or use supplemental IV injection to maintain desired effect.

Sedation of Intubated Neonates in Critical Care Settings

Neonates under 32 weeks:

A continuous infusion at a rate of 0.03 mg/kg/hr (0.5 mcg/kg/min).

Neonates 32 weeks or older:

A continuous infusion at a rate of 0.06 mg/kg/hr (1 mcg/kg/min).

Do not use loading doses in neonates. Infusion may be run more rapidly for the first several hours to establish therapeutic plasma levels. Reassess rate carefully and frequently to use the lowest possible effective dose and reduce the potential for drug accumulation. Midazolam may contain benzyl alcohol and must be used with extreme caution in neonates.

Refractory Status Epilepticus (Unlabeled)

Pediatric patients 2 months of age or older:

See Usual Dose.

DOSE ADJUSTMENTS

Reduce dose by 30% to 50%, depending on age, in the presence of narcotic premedication or other CNS depressants; see Usual Dose. ■ Reduce dose in congestive heart failure, chronic obstructive pulmonary disease, impaired hepatic or renal function, debilitated patients, and patients over 55 years of age. Half-life is extended and depressant effects will be potentiated; see Usual Dose. ■ Dose based on lean body weight in obese pediatric patients. ■ See Drug/Lab Interactions.

DILUTION

Read Label Carefully and Confirm mg Dose. Available in Two Strengths: 1 mg/mL and 5 mg/mL.

IV injection:

May administer as a 1 mg/mL solution or may be diluted with D5W or NS to permit slow titration.

Infusion:

Dilute in either D5W or NS. Manufacturer recommends a final concentration of 0.5 mg/mL. Final concentrations of 0.5 or 1 mg/mL are suggested by other sources. Use of a controlled infusion device preferred to facilitate titration and control flow to prevent overdose.

Storage:

Store unopened vials at CRT. Midazolam at a concentration of 0.5 mg/mL is **compatible** with D5W or NS for up to 24 hours.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Sedation:

Any single increment of a total dose titrated slowly over at least 2 minutes. Stop at any point that the speech becomes slurred.

Infusion:

See Usual Dose. Midazolam can accumulate in peripheral tissue, especially with long-term infusion.

Pediatric rate:

Any single increment of a total dose over a minimum of 2 to 3 minutes. Rapid injection or infusion may cause severe hypotension or seizures in infants and neonates; incidence increased with concomitant fentanyl. See comments under Infusion.

ACTIONS

A short-acting benzodiazepine CNS depressant 3 to 4 times as potent as diazepam. Has anxiolytic, sedative, anticonvulsant, muscle relaxant, and anterograde amnestic effects. CNS effects are dependent on dose, route of administration, and the presence or absence of other premedications. Induction doses can depress the ventilatory response to CO_2 stimulation. Mechanics of respiration are not adversely affected with usual sedation doses. Mean arterial pressure, cardiac output, stroke volume, and systemic vascular resistance may be slightly decreased with induction doses. May cause HRs of less than 65 beats/min to rise and more than 85 beats/min to fall. Produces sleepiness and relief of apprehension, and diminishes patient recall very effectively. Onset of action occurs within 1.5 to 5 minutes. Widely distributed. Highly protein bound, primarily to albumin. Half-life is approximately 3 hours (range is 1.8 to 6.4 hours), shorter than that of diazepam. Time to recovery is usually within 2 hours but may take as long as 6 hours. Metabolized in the liver by cytochrome P_{450}-3A4 mediation and excreted as metabolites in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

To produce preoperative sedation, anxiolysis, and amnesia. ■ May be used with or without other CNS depressants to produce sedation, anxiolysis, and amnesia before or during short diagnostic, endoscopic, or therapeutic procedures (e.g., bronchoscopy, gastroscopy, cystoscopy, coronary angiography, cardiac catheterization, oncologic procedures, radiologic procedures, suture of lacerations, and other procedures). ■ Induction of anesthesia before administration of other anesthetic agents. ■ As a component in the induction and maintenance of balanced anesthesia. ■ Continuous infusions may be used in intubated and mechanically ventilated patients for sedation as a component of anesthesia or during treatment in a critical care setting.

Unlabeled use:

Treatment of refractory status epilepticus. ■ Palliative sedation.

CONTRAINDICATIONS

Acute narrow-angle glaucoma, known hypersensitivity to midazolam, open-angle glaucoma unless receiving appropriate treatment. Not recommended in pregnancy, childbirth, breast-feeding, shock, coma, acute alcohol intoxication with depression of vital signs. Contraindicated with ritonavir (Norvir).

PRECAUTIONS

Respiratory depression and/or respiratory arrest may occur, especially when used for sedation in non–critical care settings. In some cases in which this was not recognized promptly and treated effectively, death or hypoxic encephalopathy has resulted. Should be used only in a hospital or ambulatory care setting with continuous monitoring of respiratory and cardiac function (e.g., pulse oximetry). Resuscitative drugs (including flumazenil), oxygen, and age- and size-appropriate equipment for bag/valve/mask ventilation and intubation must be immediately available. Personnel must be skilled in airway management. ■ ***A dedicated individual with no other responsibilities should monitor deeply sedated patients throughout any procedure.*** ■ Hypotensive episodes requiring treatment during or after diagnostic or surgical manipulations have been reported rarely. Occurred more commonly in patients with hemodynamic instability and in sedation studies. ■ Agitation, involuntary movements (including tonic/clonic movements and tremor), hyperactivity, and combativeness have been reported. May be due to inadequate or excessive dosing or improper administration; however, the possibility of cerebral hypoxia or a true paradoxical reaction must also be considered. ■ A topical anesthetic agent should be used with midazolam during peroral procedures, and premedication with a narcotic is recommended in bronchoscopy because increased cough reflex and laryngospasm frequently occur. Premedication with a narcotic is also recommended with balanced anesthesia. ■ For IV/IM use only. ■ May contain benzyl alcohol. Do not use for intrathecal or epidural administration. ■ Use caution in neonates. At recommended doses benzyl alcohol is not expected to be toxic, but excessive benzyl alcohol may result in hypotension, metabolic acidosis, and increased incidence of kernicterus, especially in small preterm infants. ■ Use extreme caution in elderly patients; patients with chronic disease states, decreased pulmonary reserve, or hepatic or renal impairment; and patients with uncompensated acute illness (e.g., severe fluid or electrolyte disturbances); these patients may have increased risks of hypoventilation, airway obstruction, or apnea. ■ Avoid use in patients in shock or coma or in acute alcohol intoxication with depression of vital signs. ■ Use with caution in obese patients and patients with CHF. Half-life is prolonged. ■ See Pediatric Dose and Maternal/Child for additional precautions with infants and other pediatric patients. ■ Does not protect against increased intracranial pressure or hemodynamic changes noted with succinylcholine or pancuronium or associated with intubation under light general anesthesia.

Monitor:

Obtain a careful presedation history (e.g., medical conditions, concomitant medications), and complete a physical exam. Check for airway abnormalities. ■ Monitor for early signs of hypoventilation, airway obstruction, or apnea. Respiratory and cardiac function (e.g., BP, HR, pulse oximetry) should be continuously monitored. ***Has caused apnea and cardiac/respiratory arrest.*** Monitoring of ECG desirable. Maintain a patent airway and support adequate ventilation. Record assessments using standard assessment charts for scoring, especially in pediatric patients. Monitor for both adequate and excessive sedation. ■ Vital signs should continue to be monitored during the recovery period. ■ Extravasation or arterial administration hazardous. ■ See Drug/Lab Interactions.

Patient Education:

Do not drive or operate hazardous machinery until effects of the drug have subsided or until 1 full day after anesthesia and surgery, whichever is longer. Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates) for 24 hours after last dose. Review medications and alcohol consumption with provider. ■ May impair memory; request written postoperative instructions. ■ See Maternal/Child.

Maternal/Child:

Category D: avoid pregnancy. An increased risk of congenital malformations associated with the use of benzodiazepine drugs has been suggested in several studies. ■ Not recommended during pregnancy or labor and delivery. ■ Use caution in breast-feeding. ■ Safety and efficacy of midazolam for sedation/anxiolysis/amnesia have been established in pediatric patients. However, the FDA has issued a warning stating that repeated or prolonged exposure of general anesthetics and sedation medications during the third trimester of pregnancy and in pediatric patients under 3 years of age may result in adverse cognitive or behavioral effects. See prescribing information for further discussion on risk versus benefit of use. ■ Elimination rate is faster in infants and children. Pediatric patients generally require higher dosages of midazolam (mg/kg) than do adults. ■ Neonate has reduced or immature organ function. Clearance is decreased and half-life is increased in critically ill neonates. May be susceptible to profound and/or prolonged respiratory effects. ■ See Precautions and Monitor.

Elderly:

See Usual Dose and Dose Adjustments. Start with a small dose and increase gradually based on response. ■ Clearance is reduced compared to younger adults, and time to recovery may be prolonged. ■ All elderly are more sensitive to therapeutic and adverse effects (e.g., oversedation, ataxia, dizziness). Patients over 70 years of age may be particularly sensitive. ■ See Precautions and Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

The concomitant use of benzodiazepines and **opioids** (e.g., morphine, meperidine [Demerol], fentanyl) may result in profound sedation, respiratory depression, coma, and death. Monitor for respiratory depression and sedation. ■ Concurrent use with **other CNS depressants** (e.g., alcohol, antihistamines, barbiturates, inhalation anesthetics, MAO inhibitors, phenothiazines, and tricyclic antidepressants) may result in additive effects. May increase the risk of hypoventilation, airway obstruction, desaturation, or apnea and may contribute to profound and/or prolonged effect, depress ventilatory response to CO_2, or cause hypotension. Reduce doses of midazolam. ■ **Agents that inhibit cytochrome P_{450}-3A4 activity** (e.g., triazole antifungals [e.g., itraconazole, ketoconazole], cimetidine, diltiazem, verapamil, and macrolide antibiotics [e.g., erythromycin]) decrease clearance and increase the effects of midazolam, resulting in prolonged sedation. ■ **Protease inhibitors** (e.g., indinavir, nelfinavir, and saquinavir) may increase the risk of prolonged sedation and respiratory depression. Concurrent use not recommended. ***Contraindicated with ritonavir (Norvir);*** may cause life-threatening increased sedation and respiratory depression. ■ May increase serum concentrations of **digoxin;** monitor digoxin serum levels. ■ Hypotensive effects of benzodiazepines may be increased by any **agent that induces hypotension** (e.g., antihypertensives, CNS depressants, diuretics, lidocaine, paclitaxel). Monitor BP during and after use. ■ Use with **rifampin** increases clearance and reduces effects of benzodiazepines. ■ **Theophyllines** antagonize sedative effects of benzodiazepines.

SIDE EFFECTS

The most commonly reported adverse reactions involve fluctuations in vital signs, including apnea, decreased tidal volume and/or decrease in respiratory rate, and variations in BP and HR. The majority of serious adverse effects, particularly those associated with oxygenation and ventilation, have been reported when midazolam is administered with other CNS depressant medications. The incidence of these serious events is higher in patients undergoing procedures involving the upper airway without the protective effect of an endotracheal tube (e.g., upper endoscopy or dental procedures). Serious cardiorespiratory events may include airway obstruction, apnea, hypotension (especially with narcotic premedication), oxygen desaturation, respiratory arrest, and/or cardiac arrhythmias or arrest. Inadequate or excessive dosing may cause agitation, combativeness, involuntary movements (e.g., clonic, tonic, muscle tremor), and hyperactivity; may be caused by cerebral hypoxia or be true paradoxical reactions. Other common reactions are coughing, drowsiness, headache, hiccups, nausea and vomiting, nystagmus (especially in pediatric patients), induration, redness, or phlebitis at injection site. Capable of numerous other side effects. Has caused death and hypoxic encephalopathy. Withdrawal may be seen in patients receiving an infusion for extended periods of time.

Overdose:

Sedation, somnolence, confusion, impaired coordination, diminished reflexes, coma, and untoward effect on vital signs.

ANTIDOTE

Notify the physician of all side effects. Reduction of dosage may be required or will be treated symptomatically. Discontinue the drug for major side effects or paradoxical reactions. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Flumazenil (Romazicon) will reverse all sedative effects of benzodiazepines but will not reverse the effects of other concomitant medications; see flumazenil monograph. Monitor patient for resedation, respiratory depression, and other residual adverse effects for an appropriate period after treatment. Treat hypotension with IV fluids, Trendelenburg position, or vasopressors (e.g., dopamine) as indicated. Treat hypersensitivity reactions and resuscitate as necessary.

MILRINONE LACTATE

(**MILL**-rih-nohn **LAK**-tayt)
Primacor
Antiarrhythmic Inotropic agent
pH 3.2 to 4

USUAL DOSE

Pretreatment:

See Monitor.

50 mcg/kg (0.05 mg/kg) of body weight as the initial loading dose.
Follow with a maintenance infusion according to the following chart.

Milrinone Maintenance Dose Guidelines			
	Infusion Rate (mcg/kg/min)	**Total Daily Dose (24 Hours)**	
Minimum	0.375 mcg/kg/min	0.59 mg/kg	Administer as a continuous IV infusion.
Standard	0.50 mcg/kg/min	0.77 mg/kg	
Maximum	0.75 mcg/kg/min	1.13 mg/kg	

Titrate the infusion dose between 0.375 mcg/kg/min and 0.75 mcg/kg/min (26 mcg/min and 52 mcg/min for a 70-kg person) based on hemodynamic and clinical response. Do not exceed a total dose of 1.13 mg/kg/24 hr. Duration of infusion usually does not exceed 48 hours.

DOSE ADJUSTMENTS

Reduced dose required in impaired renal function based on CrCl according to the following chart.

Milrinone Dose Guidelines in Impaired Renal Function	
Creatinine Clearance (mL/min/1.73 M²)	**Infusion Rate (mcg/kg/min)**
5 mL/min/1.73 M²	0.2 mcg/kg/min
10 mL/min/1.73 M²	0.23 mcg/kg/min
20 mL/min/1.73 M²	0.28 mcg/kg/min
30 mL/min/1.73 M²	0.33 mcg/kg/min
40 mL/min/1.73 M²	0.38 mcg/kg/min
50 mL/min/1.73 M²	0.43 mcg/kg/min

DILUTION

Loading dose:

May be given undiluted, or each 1 mg (1 mL) may be diluted in 1 mL NS or ½NS for injection. Alternately, the loading dose may be diluted with NS, ½NS, or D5W to a total volume of 10 or 20 mL for injection.

Infusion:

Dilute with NS, ½NS, or D5W. Available prediluted as 200 mcg/mL in D5W. Amount of diluent may be increased or decreased based on patient fluid requirements. Another source suggests dilution with LR.

Guidelines for Dilution of Milrinone for Infusion			
Desired Infusion Concentration (mcg/mL)	**Milrinone 1 mg/mL (mL)**	**Diluent (mL)**	**Total Volume (mL)**
200 mcg/mL	10 mL	40 mL	50 mL
200 mcg/mL	20 mL	80 mL	100 mL

May be given through Y-tube or three-way stopcock of IV infusion set but should never come in contact with furosemide. Use only freshly prepared solutions.

Filters:

No data available from manufacturer.

Storage:

Store at room temperature before dilution; avoid freezing.

COMPATIBILITY

Manufacturer states, “Do not add supplementary medications.” Forms an immediate precipitate with furosemide (Lasix).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

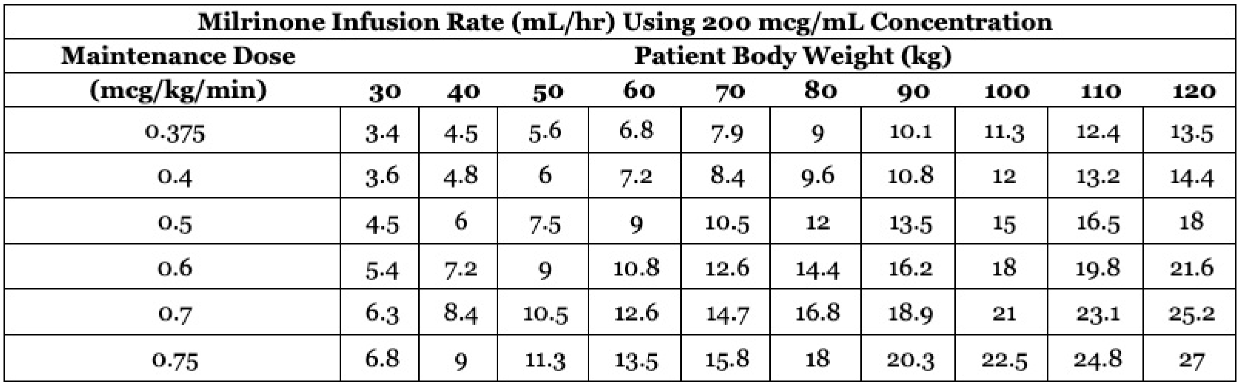
RATE OF ADMINISTRATION

Loading dose:

A single dose evenly distributed over 10 minutes.

Infusion:

Use an infusion pump to deliver milrinone in recommended doses. The following manufacturer's dose chart defines selected dose in mcg/kg/min in infusion rate of mL/hr. Adjust as indicated by physician's orders and progress in patient's condition. Reduce rate or stop infusion for excessive drop in BP.



Milrinone Infusion Rate (mL/hr) Using 200 mcg/mL Concentration

Maintenance Dose	Patient Body Weight (kg)									
(mcg/kg/min)	30	40	50	60	70	80	90	100	110	120
0.375	3.4	4.5	5.6	6.8	7.9	9	10.1	11.3	12.4	13.5
0.4	3.6	4.8	6	7.2	8.4	9.6	10.8	12	13.2	14.4
0.5	4.5	6	7.5	9	10.5	12	13.5	15	16.5	18

ACTIONS

A class of cardiac inotropic agent different in chemical structure and mode of action from digitalis glycosides and catecholamines. Similar to inamrinone, with fewer side effects. With a loading dose, peak effect occurs within 10 minutes. Continuous administration is required to maintain serum levels. It has positive inotropic action with vasodilator activity. Reduces afterload and preload by direct relaxant effect on vascular smooth muscle. Produces slight enhancement of AV node conduction. Cardiac output is improved without significant increases in HR or myocardial oxygen consumption or changes in arteriovenous oxygen difference. Pulmonary capillary wedge pressure, total peripheral resistance, diastolic BP, and mean arterial pressure are decreased. HR generally remains the same. Mean half-life is 2.4 hours. Primary route of excretion is in urine.

INDICATIONS AND USES

Short-term management of patients with acute decompensated heart failure.

CONTRAINDICATIONS

Hypersensitivity to milrinone or inamrinone.

PRECAUTIONS

Not shown to be safe or effective for use longer than 48 hours. No improvement in symptoms and an increased risk of death have been reported. ■ Use caution in impaired renal function; serum levels may increase considerably. ■ May be given to digitalized patients without causing signs of digoxin toxicity; correct hypokalemia with potassium supplements. ■ May increase ventricular response in atrial flutter/fibrillation. Consider pretreatment with digoxin. ■ Additional fluids and electrolytes may be required to facilitate appropriate response in patients who have been vigorously diuresed and may have insufficient cardiac filling pressure. Use caution. ■ Safety for use in the acute phase of myocardial infarction not established. ■ Should not be used in patients with severe obstructive aortic or pulmonary valvular disease in lieu of surgical relief of the obstruction. May aggravate outflow tract obstruction in hypertrophic subaortic stenosis.

Monitor:

Observe closely. Continuous ECG monitoring required to allow for prompt detection and management of cardiac events, including life-threatening ventricular arrhythmias. Emergency equipment must be readily available. ■ Monitoring of BP, urine output, renal function, fluid and electrolyte changes (especially potassium), liver function tests, and body weight is recommended. ■ Monitoring of cardiac index, pulmonary capillary wedge pressure, central venous pressure, and plasma concentration is very useful. ■ Observe for orthopnea, dyspnea, and fatigue. ■ Reduce rate or stop infusion for excessive drop in BP. ■ As cardiac output and diuresis improve, a reduction in diuretic dose may be indicated. ■ Possible risk of arrhythmias. Risk further increased with excessive diuresis and/or hypokalemia. Replace potassium as indicated. ■ Infusion site reactions may occur. Monitor site carefully.

Maternal/Child:

Category C: safety for use during pregnancy, breast-feeding, and in pediatric patients not established. Use during pregnancy only if potential benefit justifies potential risk.

Elderly:

Consider impaired renal function; may require a reduced dose.

DRUG/LAB INTERACTIONS

May cause additive hypotensive effects with **any drug that produces hypotension** (e.g., alcohol, benzodiazepines, lidocaine). ■ See Monitor.

SIDE EFFECTS

Supraventricular and ventricular arrhythmias including nonsustained ventricular tachycardia do occur; rare cases of torsades de pointes have been reported. Abnormal liver function tests, anaphylactic shock (rare), angina, bronchospasm, chest pain, headaches, hypokalemia, hypotension, infusion site reactions, rash, and tremor have been reported.

ANTIDOTE

Notify the physician of any side effect. Based on degree of severity and condition of the patient, may be treated symptomatically, and dose may remain the same, be decreased, or the milrinone may be discontinued. Reduce rate or discontinue the drug at the first sign of marked hypotension and notify the physician. May be resolved by these measures alone or vasopressors (e.g., dopamine) may be required. Treat dysrhythmias with the appropriate drug. Resuscitate as necessary.

MINOCYCLINE HYDROCHLORIDE

(mih-no-**SYE**-kleen hy-droh-**KLOR**-eyed)
Minocin
Antibacterial (tetracycline) Antiprotozoal
pH 4.5 to 5

USUAL DOSE

Pretreatment:

Baseline studies suggested; see Monitor.

An initial dose of 200 mg as an infusion. Follow with 100 mg every 12 hours. Do not exceed 400 mg/24 hr. Initiate oral dosing as soon as possible.

PEDIATRIC DOSE

Pediatric patients over 8 years of age:

An initial dose of 4 mg/kg of body weight. Follow with 2 mg/kg every 12 hours. Do not exceed adult dose. Transfer to PO dosing as soon as practical.

DOSE ADJUSTMENTS

In patients with renal impairment, do not exceed a dose 200 mg/24 hr. ■ Caution and lower-end dosing suggested in elderly patients. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Reconstitute each 100-mg vial with 5 mL SW. Must be further diluted immediately with 100 to 1,000 mL of NS, dextrose solutions, dextrose in saline solutions, or 250 to 1000 mL LR.

Storage:

Store unopened vials at CRT. Properly diluted solutions should be used immediately but are stable for up to 4 hours at RT or up to 24 hours if refrigerated. Discard any unused portion after 24 hours.

COMPATIBILITY

Manufacturer indicates that minocycline may not be diluted in solutions containing calcium other than LR. A precipitate may form, especially in neutral or alkaline solutions. Additives or other medications should not be added to the minocycline vial or infused simultaneously through the same IV line, including Y-connectors. If the same IV line is used for sequential infusion of additional medications, the line should be flushed before and after infusion of minocycline with NS, dextrose, dextrose in saline solutions, or LR.

RATE OF ADMINISTRATION

A single dose equally distributed over 60 minutes. Avoid rapid administration; may increase incidence of side effects.

ACTIONS

A broad-spectrum, semi-synthetic derivative of tetracycline that is bacteriostatic against many gram-positive and gram-negative organisms. Cross-resistance of these bacteria to tetracyclines is common. Mode of action is thought to be interference with protein synthesis. Well distributed in most body tissues. Half-life ranges from 15 to 23 hours. Partially metabolized in the liver and excreted in bile, urine, and feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of specific bacterial infections caused by susceptible isolates of specific bacteria; see prescribing information. ■ As an alternative agent for treatment of infections caused by susceptible organisms in patients allergic to penicillin.

CONTRAINDICATIONS

Hypersensitivity to minocycline or its components and other tetracyclines (e.g., doxycycline). ■ Not recommended in pediatric patients under 8 years of age unless expected benefits outweigh serious risks.

PRECAUTIONS

To reduce the development of drug-resistant bacteria, antibiotics should be used only to treat appropriate bacterial infections. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to minocycline. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ May cause an increase in BUN. Usual doses in patients with impaired renal function may cause accumulation and result in azotemia, hyperphosphatemia, acidosis, and liver toxicity. See Dose Adjustments and Monitor. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported; may range from mild to life threatening. Consider in patients who present with diarrhea during or after treatment with minocycline. ■ Organisms resistant to one tetracycline are usually resistant to others. ■ Use with caution in patients with impaired hepatic function; hepatotoxicity has been reported; see Drug/Lab Interactions. ■ Pseudotumor cerebri (intracranial hypertension [IH]) has been reported in adults. S/S include blurred vision, diplopia, headache, and vision loss. Papilledema can be found on fundoscopy. Women of childbearing age who are overweight or have a history of IH are at greater risk of developing tetracycline-associated IH. ■ Not indicated for use during tooth development (in utero, infancy, and childhood) unless other drug options may not be effective or are contraindicated; see Maternal/Child. ■ Drug rash with eosinophilia and systemic symptoms (DRESS), including some fatal cases, have been reported; see Antidote. ■ Minocycline for injection contains magnesium sulfate heptahydrate. Use with caution in patients with renal impairment, heart block, or myocardial damage.

Monitor:

Determine absolute patency of vein and avoid extravasation. Monitor injection site for thrombophlebitis. ■ Baseline and periodic monitoring of CBC with differential and platelet count and renal and hepatic function tests are suggested. ■ Test patients with gonorrhea with a serologic test for syphilis at diagnosis. Retesting in 3 months is indicated. ■ Due to anti-anabolic effect of tetracyclines, monitoring of creatinine and BUN indicated in patients with impaired renal function. ■ If visual disturbance occurs during treatment, prompt ophthalmologic evaluation is warranted. Patients should be monitored until vision stabilizes. See Dose Adjustments and Precautions. ■ Because minocycline for injection contains magnesium, close monitoring is recommended in patients with heart block or myocardial damage. ■ Monitor magnesium levels in patients with renal impairment.

Patient Education:
